2052. Stolzenburg, U. (2000): Nachweis der Arktischen Smaragdlibelle (*Somatochlora arctica* Zetterstedt, 1840) in der Radeburger Heide. Veröff. Mus. Westlausitz Kamenz 22: 93-96. (in German). [Saxonia, Germany, Landkreis Meißen, NSG "Töpfergrund in der Radeburger Heide"; *S. arctica* was recorded in June / July 2000 and May/June 2001. The habitat and co-occurring odonate species are described, and some conservation measures are proposed.] Address: Stolzenburg, U., Bärnsdorfer Str. 1a, D-01471 Berbisdorf, Germany

2053. Tanaka, S. (2000): Induction of darkening by corazonins in several species of Orthoptera and their possible presence in ten insect orders. *Applied Entomology & Zoology* 35(4): 509-517. (in English). ["(His7)-corazonin is known to play an important role in the control of body-color polymorphism in the migratory locust, *Locusta migratoria* (Orthoptera: Acrididae). Another neuropeptide, (Arg7)-corazonin, which has been isolated from other insects, is also known to induce darkening in this locust. These two neuropeptides were injected into nymphs of other orthopteran species to determine if they could induce darkening in those species. The test species belonged to 4 families: Acrididae (*Acrida cinerea*, *Gastrimargus marmoratus* and *Nomadacris succincta*), Catantopidae (*Oxya yezoensis*), Pyrgomorphidae (*Atractomorpha lata*), and Tettigoniidae (*Euconocephalus pallidus*). Except for the katydid, *E. pallidus*, all species injected with 1 nmol of (His7)-corazonin turned dark as compared with oil-injected controls. (Arg7)-corazonin showed a similar effect in the two acridid species tested, but no effect in the katydid. These results suggest that (His7)-corazonin or a similar neuropeptide may be involved in the control of body color in the locusts and grasshoppers, but not in the katydid. When a brain and/or corpora cardiaca (CC)

When a brain and/or corpora cardiaca (CC) taken from nymphs of each test species were implanted in albino nymphs of *L. migratoria*, dark color was induced in the latter, indicating that all test orthopterans contained some factor identical or similar to (His7)- or (Arg7)-corazonin. Likewise, brain-CC complexes from 47 other species of 10 insect orders including Orthoptera, Dermaptera, Dictyoptera, Isoptera, Homoptera, Hemiptera, Odonata, Hymenoptera, Lepidoptera, and Diptera induced darkening in albino locusts, whereas those from 8 species of Coleoptera all failed to do so." 2057. Zipfel, C.; Xylander, W.E.R. (2000): Zoogeographical investigations on *Cercion lindenii* (Odonata, Coenagrionidae) based on morphometry and isoenzyme-PAGE. *Zoology* 103 (Suppl. 3): 14. (in English). [Verbatim: *C. lindenii* occurs in Germany with at least two isolated populations that are considered to represent different subspecies. *C. lindenii* has been increasing its zoogeographical distribution significantly since the early eighties and the isolation may be overcome within the next years. In this investigation, therefore, 117 adult specimens from five localities have been investigated regarding their wing morphometry and protein differences in electrophoresis: two each from southwestern (Giessen, Hessen; St. Leon, Baden-Württemberg) and central (Rheine, Nordrhein-Westfalen; Hameln, Niedersachsen), and one from eastern Germany (Großer Schwansee, Brandenburg). Wing morphometry showed significant differences (euclidean distance and UPGMA) between the eastern and all other populations. The males of the eastern population had larger wings whereas there was no significant difference between the females. This corresponds to earlier results (Beutler, H., 1985, *Faun. Abh. Staatl. Mus. Tierk., Dresden* 49, 82) but may, however, not definitively indicate the occurrence of an eastern subspecies, whereas odonate populations from colder regions tend to have larger wings (Carius, W., 1993, Dissertation,

Univ. Bremen). 5 of 21 enzymes tested were polymorphic (IDH, esterases, PGM, GPD, diaphorase); in all cases but one the less frequent allele(s) occurred only in heterozygotes. Specimens from central Germany showed the highest heterozygosity (up to half of the population in IDH) whereas all other locations tested showed very high frequencies of one allele and low frequencies of all others or were homozygote. Also similarities between distant populations are often higher than to those from nearer locations. Regarding the isoenzyme patterns found, the German *C. lindenii* populations appear to be biochemically rather uniform and the variability is too low for postulating two subspecies. The evaluation of the total protein spectrum, however, showed that two groups can be differentiated: one group comprising all western populations investigated (Hameln, Rheine, Giessen, St. Leon) showed a homogeneous pattern of protein bands (within and between populations). The protein samples from the Schwansee population, however, differed significantly. The similarity between the Schwansee and the other populations decreased continuously from north to south.] Address: Zipfel, C., Staatliches Museum für Naturkunde Görlitz, PF 300154, D-02806 Görlitz, Germany

2058. Andrés, J.A.; Cordero Rivera, A. (2001): Survival rates in a natural population of the damselfly *Ceragrion tenellum*: effects of sex and female phenotype. *Ecological Entomology* 26: 341-346. (in English). ["1. *Ceragrion tenellum* females show genetic colour polymorphism. Androchrome (erythrogastrum) females are brightly (male-like) coloured while gynochrome females (typica and melanogastrum) show cryptic colouration. 2. Several hypotheses have been proposed to explain the existence of more than one female morph in damselfly populations. The reproductive isolation and intraspecific mimicry hypotheses predict greater survival of gynochrome females, while the density dependent hypothesis predicts no differential survival between morphs. 3. Mature males had greater recapture probability than females while the survival probability was similar for both sexes. Survival and recapture rates were similar for androchrome and gynochrome females. 4. Gynochrome females showed greater mortality or migration rate than androchrome females during the pre-reproductive period. This result is not predicted by the above hypotheses or by the null hypothesis that colour polymorphism is only maintained by random factors: founder effects, genetic drift, and migration." 2059. Andrew, R.J. (2001): Evidence of sperm displacement in *Ischnura aurora* (Brauer) (Zygoptera: Coenagrionidae). *Odonatologica* 30(4): 435-439. (in English). ["Five spindle-shaped sperm 'pellets' (bundles) were found in the vagina of copulation-interrupted androchrome female. The second and third pellets had a long thin tail while the fourth had partly and the fifth completely disintegrated. In an other female, the vagina was packed with sperm material even though the sperm storage organs (spermatheca and bursa copulatrix) were completely filled. It is proposed that this sp. exhibits a transitional reproductive behaviour with respect to

sperm competition." (Author)] Address: Andrew, R.J., Department of Zoology, Shri Shivaji ESA's Science College, Congress Nagar, Nagpur - 440012 (MS), India

2060. Anholt, B.; Vorburger, C.; Knaus, P. (2001): Mark-recapture estimates of daily survival rates of two damselflies (*Coenagrion puella* and *Ischnura elegans*). *Canadian Journal of Zoology* 79(5): 895-899. (in English with French summary). ["Male-biased operational sex ratios are very common in sexually mature dragonflies. These may be due to differential survival or differences in time spent at the breeding site by the sexes. Because most studies are carried out at the breeding site, these two processes can be measured as survival rates or recapture rates using modern capture-mark-recapture methods. We marked 66 female and 233 male *Coenagrion puella*, and 137 female and 347 male *Ischnura elegans* during three capture periods spread over 18 days. Each time an animal was recaptured it was remarked so that the capture history of any captured animal could be readily identified. We recaptured 131 *C. puella* and 55 *I. elegans* at least once. We used the Cormack-Jolly-Seber model to estimate the daily probability of survival and recapture. The probability of recapture was, on average, more than three times higher for male *C. puella* (0.489) than females (0.133) with significant day to day variation. The daily probability of survival did not differ significantly between the sexes (0.860), with no significant variation among days. In contrast, in *I. elegans* the probability of recapture did not differ between the sexes (0.139 for the first 5 days; between 0.032 and 0.287 for the final 3 days), but the daily probability of surviving was much higher for males (0.812) than for females (0.579). Assuming that the sex ratio was unity at sexual maturity, the recapture and survival rates predicted well the sex ratio of the sample of *C. puella* but predicted more males than were observed in the sample of *I. elegans*. This suggests that male *I. elegans* may suffer higher mortality than females in the immature stage." 2062. Artiss, T.; Schultz, T.R.; Polhemus, D.A.; Simon, C. (2001): Molecular phylogenetic analysis of the dragonfly genera *Libellula*, *Ladona*, and *Plathemis* (Odonata: Libellulidae) based on mitochondrial cytochrome oxidase I and 16S rRNA sequence data. *Molecular Phylogenetics & Evolution* 18(3): 348-361. (in English). ["Molecular phylogenetic relationships among members of the odonate genus *Libellula* (Odonata: Anisoptera: Libellulidae) were examined using 735 bp of mitochondrial COI and 416 bp of 16S ribosomal RNA gene sequences. Considerable debate exists over several relationships within *Libellula*, as well over the status of two putative genera often placed as subgenera within *Libellula*: *Ladona* and *Plathemis*. Parsimony and maximum-likelihood analyses of the separate and combined data sets indicate that *Plathemis* is basal and monophyletic and that *Ladona* is the sister clade to the remainder of *Libellula sensu stricto* (s.s.) (all species within the genus *Libellula*, excluding *Plathemis* and *Ladona*). Moreover, two European taxa, *Libellula fulva* and *L. depressa*, were found to occupy a sister group relationship within the *Ladona* clade. Relationships within *Libellula* s.s. are less well resolved. However, monophyletic lineages within the genus are largely consistent with morphologically based subgeneric classifications. Although tree topologies from each analysis differed in some details, the differences were in no case statistically significant. The analysis of the combined COI and 16S data yielded trees with overall stronger support than analyses of either gene alone. Several analyses failed to support the monophyly of *Libellula sensu lato* due to the inclusion of one or more outgroup species. However, statistical comparisons of topologies produced by unconstrained analyses and analyses in which the monophyly of *Libellula* was constrained indicate that any differences are nonsignificant. Based on morphological data, we therefore reject the paraphyly of *Libellula* and accept the outgroup status of *Orthemis ferruginea* and *Pachydiplax longipennis*." 2063. Babbitt, K.J. (2001): Behaviour and growth of southern Leopard frog (*Rana sphenoccephala*) tadpoles: Effects of food and predation risk. *Canadian Journal of Zoology* 79(5): 809-814. (in English with French summary). ["I examined the effects of a nonlethal predator, larvae of the odonate *Anax junius*, and food-resource level on behaviour and growth of larval southern Leopard frogs (*Rana sphenoccephala*) to test whether the strength of effects of a nonlethal predator was influenced by background resource level. I crossed two levels of food resources, growth-limiting and non-growth-limiting, with the presence or absence of *A. junius*. Tadpoles responded to predators by altering spatial distribution and activity. When predators were present, tadpoles on both food treatments had similar low levels of activity, but tadpoles on the nonlimiting food treatment showed a much larger reduction in activity than tadpoles on the growth-limiting treatment. Tadpoles on both food treatments delayed metamorphosis when exposed to predators. Growth and size at metamorphosis were affected significantly by food treatment but not by predator treatment. However, the direction of response to predators differed. Tadpoles on the growth-limiting treatment were larger at metamorphosis and grew faster when exposed to predators; the opposite was true for tadpoles on the non-growth-limited food treatment. This raises the interesting possibility that for some species experiencing low resource availability, predators may induce a behaviourally mediated positive effect on growth." 2064. Baptista, D.F.; Dorville, L.; Buss, D.F.; Nessiamian, J.L. (2001): Spatial and temporal organization of aquatic insects assemblages in the longitudinal gradient of a tropical river. *Brazilian Journal of Biology* 61(2): 295-304. (in English with Portuguese summary). ["The distribution and abundance of aquatic insects were studied in the longitudinal gradient of the watershed of Macae River, a coastal Atlantic Forest river in Southeastern Brazil. Sampling stations were selected in the first, second, fourth, fifth, and sixth orders and sampled in April, July, and October 1995. This represented the end of the rainy season, the dry season, and the beginning of another rainy season, respectively. In each month four samples were collected using a Surber sampler from each of the following substrates: sand, litter deposited in pool areas, litter in riffle areas, and stones. A total of 46,431 specimens of aquatic insects belonging to ten orders were obtained. The data were analyzed by the multivariate methodologies of Correspondence Analysis (CA) and Cluster Analysis (UPGMA) using the similarity index of Morisita, for all three months. Both showed a significant faunal disruption in the river, which can be divided in two sections: the upper one, from first to fourth orders, and the lower section, including fifth and sixth orders. The same results were obtained with presence-absence matrices, using Jaccard similarity index, showing that the changes are not only due to quantitative differences. A Mantel test was used to compare the assemblage composition temporally and no difference was detected between the three months. Moreover, a Canonical Correspondence Analysis (CCA) was applied to the data to check which of the 14 physical and chemical variables significantly

explained macro-invertebrate community variation. The most significant variables were conductivity, CPOM, and pH for the upper stations (1st, 2nd and 4th orders), and alkalinity, FPOM, and HCO₃ for the lower stations (5th and 6th orders)." 2065. Benke, A.C.; Wallace, J.B.; Harrison, J.W.; Koebel, J.W. (2001): Food web quantification using secondary production analysis: Predaceous invertebrates of the snag habitat in a subtropical river. *Freshwater Biology* 46(3): 329-346. (in English). ["1. Secondary production was estimated for Plecoptera, Odonata and Megaloptera (mostly large predators) occurring on the snag habitat of a subtropical blackwater river in the southeastern U.S.A. Coastal Plain for 2 years. Production estimates and gut analyses were used in estimating species-specific ingestion to construct a quantitative foodweb of the predator portion of the invertebrate assemblage. Neither basal resources (e.g. detritus) nor predaceous vertebrates (e.g. fishes) were considered in this analysis. A discharge-specific model of snag-habitat availability was used to convert values per m² of snag surface to values per m² of river bed. 2. These three orders included the major large predators on the snag habitat, as well as two detritivorous stoneflies. The major predators were the hellgrammite (*Corydalus cornutus*), five perlid stoneflies (*Paragnetina kansensis*, *Perlesta placida*, *Neoperla clymene*, *Acroneturia evoluta* and *A. abnormis*) and two dragonflies (*Neurocordulia molesta* and *Boyeria vinosa*). The detritivores were *Pteronarcys dorsata* and *Taeniopteryx lita*. 3. Total predator production was high, but varied from only 7.1 to 7.4 g dry mass (DM) m⁻² y⁻¹ of snag surface (2.4-2.7 g DM m⁻² y⁻¹ of river bed) over two years. *Corydalus* was the largest predator and had the highest production (2.8-3.1 g DM m⁻² of snag surface). The most productive stoneflies were *Perlesta* (0.7-1.0 g DM m⁻² of snag surface) and *Paragnetina* (1.0-1.3 g DM m⁻² of snag surface). The most productive dragonfly was *Neurocordulia* (0.7-1.9 g DM m⁻² of snag surface). Production of the non-predaceous stoneflies was 1.0-2.3 g DM m⁻² of snag surface. Production values per m² of river bed were 2-3.5 times lower than the values per m² snag surface. 4. Measurement of ingestion fluxes within the predator portion of the food web showed that predaceous invertebrates were primarily supported by chironomid and mayfly prey. However, the greatest consumption of chironomids and mayflies was by omnivorous hydropsychid caddisflies, which had a considerably higher production than the larger predators. There was a hierarchy of feeding with *Corydalus* as top predator consuming all other groups, followed in order by dragonflies, stoneflies and hydropsychids. Although the feeding hierarchy suggested the presence of four predatory trophic levels within the invertebrate assemblage, calculations of trophic position indicated there were less than two. With primary consumers (e.g. midges) having a trophic position of 2, *Corydalus* had a trophic position of only 3.5. 5. A relatively high fraction of invertebrate production was consumed by predaceous invertebrates, ranging from 9 to > 100% for various primary consumer groups, with total consumption representing 52% of total production. Because these estimates do not include vertebrate consumption or emergence, it means that a high fraction of larval mortality is due to predation."

2066. Benstead, J.P.; Barnes, K.H.; Pringle, C.M. (2001): Diet, activity patterns, foraging movement and responses to deforestation of the aquatic tenrec *Limnogale mergulus* (Lipotyphla: Tenrecidae) in eastern Madagascar. *Journal of Zoology (London)* 254(1): 119-129. (in English). ["The aquatic or web-footed tenrec *Limnogale mergulus* is a semi-aquatic lipotyphlan insectivore known only from stream habitats of eastern Madagascar. *Limnogale* is considered a high conservation priority because of its rarity, suspected vulnerability to habitat degradation, and unique ecological niche on the island. However, its ecology and behaviour remain poorly understood. Quantitative faecal analysis and radio-tracking were used to study the diet and foraging activity of *Limnogale* in eastern Madagascar. Faecal pellet counts along forest and zero-canopy streams were also conducted to examine the response of aquatic tenrec populations to catchment deforestation. Faecal analysis indicated that the diet of *Limnogale* consists mainly of larval and adult aquatic insects, larval anurans and crayfishes. The most important prey were Ephemeroptera, Odonata and Trichoptera larvae. Diets did not differ substantially between forest and zero-canopy streams. Radio-tracking of two individuals indicated that *Limnogale* is strictly nocturnal and remains in streamside burrows during daylight. Nocturnal movement was restricted solely to stream channels and consisted of active foraging by swimming and diving. Distance travelled per night ranged from 200 to 1550 m along the stream channel (means 1067 and 860 m, respectively). The total lengths of stream channel used by the two aquatic tenrecs during each radio-tracking study were 1160 and 505 m, respectively. Faecal pellet counts along forest and zero-canopy streams suggested that *Limnogale* was at least as abundant in zero-canopy streams. This finding suggests that *Limnogale* is not an obligate forest species; however, it preys on benthic communities that are extremely vulnerable to sedimentation. Control of excessive sedimentation and maintenance of healthy benthic communities are essential to *Limnogale* conservation. We include an updated list of known sites for *Limnogale* and recommend the use of faecal pellet surveys to assess the current distribution of the species." 2067. Benzler, A. (2001): Seltene, bedrohte und endemische Tier- und Pflanzenarten - Auswahl von Artengruppen und Arten für ein bundesweites Naturschutzmonitoring. *Natur und Landschaft* 76(2): 70-87. (in German with English summary). ["In 1999 a nationwide monitoring concept for nature conservation was elaborated by a working group comprising experts of the nature conservation authorities of the German federal states (Länder) and the German Federal Agency for Nature Conservation. This was spurred by the lack of biotic data on national level, which is needed urgently in order to evaluate biodiversity status and trends, and to provide arguments for the policy process. This paper considers only one component of the overall concept, namely the monitoring of rare, threatened and endemic animal and plant species. Three groups of species are considered; species which must be monitored under

commitments resulting from international agreements and directives, species which are the object of particular German responsibility (e.g. endemic species) and species which are the focus of conflicts between nature conservation and land-use interests. The objective of monitoring is to meet the need for nation-wide representative data on these species. The paper describes the methods of selecting systematic species groups and species, and presents the species lists in an annex. There is a need for further work to develop monitoring methods." *Aeshna viridis*, *Coenagrion hylas*, *C. mercuriale*, *Epitheca bimaculata*, *Stylurus flavipes*, *Leucorrhinia albifrons*, *L. caudalis*, *L. pectoralis*, *Nehalennia speciosa*, *Ophiogomphus cecilia*, *Oxygastra curtisii*, and *Sympecma paedisca* are selected for odonatological monitoring.] Address: Benzler, A., Bundesamt für Naturschutz, Konstantinstr. 110, D-53179 Bonn, Germany

2068. Bilton, D.T.; Foggo, A.; Rundle, S.D. (2001): Size, permanence and the proportion of predators in ponds. *Arch. Hydrobiol.* 151(3): 451-458. (in English). ["The species richness and proportion of predatory species were investigated in ponds of differing area and permanence on the Lizard Peninsula, West Cornwall, UK, an area with a high density of seasonally fluctuating waterbodies, and a rich aquatic biota. A total of 169 taxa [including "Odonata"] were identified through monthly sampling of 16 ponds. Permanence, rather than pond area, was strongly related to overall species richness and the proportion of predators found. These results contrast with other studies which have shown strong effects of area on such community parameters. We suggest that issues of scale, and differences in regional species pools account for these contrasting results, and should be considered when searching for common factors underlying community attributes." 2069. Bönsel, A. (2001): Zusammenhänge zwischen der Gewässereutrophierung und der Ausbreitung von *Erythromma viridulum* (CHARP. 1840) (Zygoptera: Coenagrionidae), am Beispiel von Mecklenburg-Vorpommern. *Zeitschrift für Ökologie und Naturschutz* 9: 211-217. (in German with English summary). ["*E. viridulum* obviously established local populations only during the last 10-20 years in the northern part of Mecklenburg-Vorpommern. Only in the southern part the species was found already in the 1960's. At the end of the 20th century it occurred all over the county [...]. The phenomenon of expansion was not connected with the global climate change. It was rather the water eutrophication that created the conditions for a successful establishment of the originally Mediterranean species in northern Central Europe. Eutrophication supported the expansion of *Ceratophyllum* species. The enormous biomass production caused foul sludge deposits which entailed a decreasing water level. Shallow waters warm up rapidly. So numerous thermically favourable larval waters were created for the Mediterranean species. Besides few predatory species or other dragonflies were found amongst the tangle of the *Ceratophyllum*-population. This missing pressure by competition and predators is also considered as a favourable habitat constellation for the establishment of *Erythromma viridulum*." 2070. Borisov, S.N.; Haritonov, A.Y. (2001): A study of dragonflies of central Asian Nature Reserves. *Belyshevia* 1(1): 2-5. (in Russian, with short English summary). [In Central Asia 15 Nature Reserves were established; 7 of them - the one with information of their odonate fauna - are shortly characterised. The Odonata are presented in a checklist with information on their presence in the very Nature Reserve. It is not clear if the list was checked critically, for it seems impossible that e.g. *Coenagrion scitulum* is occurring in the region (The species was given for the nature Reserve Ramit).] Address: Haritonov, A.YU.; Laboratory of Insect Ecology, Biological Institute of the Siberian Branch of the Academy of Sciences, Frunze str. 11, RUS-630091 Novosibirsk, Russia

2071. Braune, P.; Rolff, J. (2001): Parasitism and survival in a damselfly: Does host sex matter? *Proc. Royal Soc. Biol. Sci. Ser. B* 268(1472): 1133-1137. (in English). ["We present experimental data on the survivorship of damselflies infested by parasitic water mites from a population in field cages. In addition, we show correlative laboratory data under simulated severe weather conditions. In the manipulative experiment, parasitized females' individual condition, which was measured as weight at emergence, was an important determinant of survival under field conditions. In contrast, such a relationship did not occur in males and unparasitized females. It was found in the laboratory experiment that water mites as well as weight at emergence both contributed significantly to the reduced survivorship of male and female damselflies. It was concluded that the impact of parasitism depends on environmental conditions and that host sexes differ in their responses to parasitism. This is discussed in the light of immunocompetence in invertebrates." 2072. Bree, D. (2001): Further notes on the Odonata of Sandbanks Provincial Park. In: Cating, P.M., C.D. Jones & P. Pratt (Eds): *Ontario Odonata*, vol. 2. Toronto Entomologist's Association, Toronto, Ontario: 24-26. (in English) ["Records on flight periods, abundance, and behaviour are provided for 17 species of odonates from Sandbanks Provincial Park, Ontario. *Aeshna canadensis*, *Sympetrum internum*, and *S. semicinctum* are added to the park list, while *Argia jumipennis violacea* is removed." (Author)] Address: Bree, D., Box 123, Bloomfield, Ontario K0K 1G0, Canada. E-mail: dbree@post.kosone.com

2073. Buczynski, P. (2001): Dragonflies (Insecta: Odonata) of the Krzczonowski Landscape Park. *Park Narodowe i Rezerwat Przyrody* 20(1): 63-78. (in Polish with English summary). [The area of Krzczonowski Landscape Park is deforested and impacted by an intensive agriculture. Water basins occur almost exclusively in river valleys. The rivers Gieiczew, Gielczewka and Olszanka drain the area. They are free of organic pollution. Only the Olszanka is impacted by poultry droppings. The rivers are partially regulated and their valleys are reclaimed. Dragonflies were studied in the years 1998 - 2000 at 38 localities of which only 26 are dragonfly habitats. 37 species have been found. The

species number is low, especially compared with other protected areas in the SE Poland (e.g. Poleski National Park: 52 species, Janowskie Forests Landscape Park: 58). Only 13 species occurred outside of the river valleys, but all species are representatives of the "valley-fauna": 15 species were collected in the Olszanka, 24 in the GieJczewka, and 36 in the Gietczew valley. The highest diversity was found at ponds and small pools.] Address: Buczynski, P., Dept of Zool., Marie Curie-Sklodowska University, Akademicka 19, PL-20-033 Lublin, Poland. E-mail: pbuczyns@biotop.umcs.lublin.pl

2074. Buczynski, P. (2001): The first record of *Coenagrion armatum* (Charpentier, 1840) (Odonata: Coenagrionidae) from the Roztocze Upland. *Wiad. entomol.* 20(1-2): 87-88. (in Polish). [The in Poland "Critically Endangered" *C. armatum* was discovered in May 2000 in the floodplain of River Wieprz near the village Gućiów. Locality, habitat and co-occurring species are described, and the current situation of the species in Poland is discussed.] Address: Buczynski, P., Dept of Zool., Marie Curie-Sklodowska University, Akademicka 19, PL-20-033 Lublin, Poland. E-mail: pbuczyns@biotop.umcs.lublin.pl

2075. Buskirk, J. van; Saxer, G. (2001): Delayed costs of an induced defense in tadpoles? Morphology, hopping, and development rate at metamorphosis. *Evolution* 55(4): 821-829. (in English). ["Models for the evolution of plasticity predict that individuals having phenotypes induced by exposure to enemies should experience relatively low fitness when enemies are absent. However, costs of induced phenotypes have been difficult to find in both plants and animals, perhaps because costs are expressed at later stages in the life cycle. We searched for delayed costs of an induced defense in larvae of the water frog *Rana ridibunda*, which exhibits strong phenotypic responses to predators. Tadpoles grew to metamorphosis in outdoor artificial ponds, in either the presence or absence of *Aeshna* dragonfly larvae confined within cages. We collected metamorphs at forelimb emergence, estimated their development rate until tail resorption was complete, and measured their body and leg shape and hopping performance. Development rate through metamorphosis reflects the duration of a transitional period during which metamorphs are especially vulnerable to predators, and hopping performance may reflect ability to escape predators. Froglets from the dragonfly treatment lost mass through metamorphosis significantly faster than those from predator-free ponds, but they resorbed their tails at about the same rate, despite the fact that their tails were relatively large to begin with. Froglets developing from predator-induced tadpoles had shorter, more muscular legs, and hopped 5% longer distances (difference not significant). Therefore, producing an induced defense against insect predators during the tadpole stage did not exact a cost during or immediately after metamorphosis; if anything, tadpoles with the predator-induced phenotype gave rise to more vigorous froglets. These results focus attention on other costs of the induced phenotype, as well as alternative explanations for plasticity that do not rely on direct fitness trade-offs." (Authors)] Address: Buskirk, J. van, Institute of Zoology, University of Zürich, CH-8057 Zürich, Switzerland. E-mail: jvb@zool.unizh.ch

2076. Buskirk, J. van (2001): Specific induced responses to different predator species in anuran larvae. *Jour. evol. biol.* 14(3): 482-489. (in English). ["Models of de-

fence against multiple enemies predict that specialized responses to each enemy should evolve only under restrictive conditions. Nevertheless, tadpoles of *Rana temporaria* can differentiate among several predator species. Small tadpoles used a refuge when *Notonecta* backswimmers were in the pond, but showed a weaker hiding response to adult *Triturus alpestris* newts and no response to aeshnid dragonfly larvae (*Aeshna* and *Anax*). All predators caused a decline in feeding and swimming activity. Large tadpoles reserved the strongest behavioural response for dragonflies, while *Triturus* caused no response. The shift during development suggests that tadpoles distinguished among predators, rather than exhibiting a graded dosage response to a single cue associated with predation. Information on habitat distributions of predators suggests that they are regularly encountered, which would facilitate evolution of adaptive behavioural responses. Morphological responses to all predators were similar, perhaps because similar morphologies defend against all four predators. The evolutionary maintenance of specialized responses to multiple predators may be possible because adaptive responses do not conflict and the predators themselves do not interact strongly." (Author)] Address: Buskirk, J. van, Inst. Zool., Univ. of Zürich, CH-8057 Zürich, Switzerland. E-mail: jvb@zool.unizh.ch

2077. Carchini, G.; Chiarotti, F.; Di Domenico, M.; Mattocchia, M.; Paganotti, G. (2001): Fluctuating asymmetry, mating success, body size and heterozygosity in *Coenagrion scitulum* (Rambur) (Odonata: Coenagrionidae). *Animal Behaviour* 61(3): 661-669. (in English). ["For decades fluctuating asymmetry (FA) has been considered a good descriptor of developmental stability. Correlations have been shown between FA and several fitness components, including mating success and heterozygosity level. However, some doubts have been expressed about the generalization of these results, perhaps because of bias towards positive results and a poor critical approach in the first phase of FA studies. Studies on Odonata are scarce and are concentrated on the Coenagrionidae family, with contrasting results in the relationships between FA and mating success, size and other fitness components. We investigated the relationships between FA expressed as right - left wing length ($R - L$), body size expressed as $(R+L)/2$, multilocus and single locus heterozygosity assessed by allozyme electrophoresis and short-term mating success (SMS) assessed from the status (mated or not) of the males at the moment of collection. We collected 260 males from a breeding population. The data were analysed by both univariate and multifactorial statistical methods. After excluding a correlation between FA and body size, we checked the presence of a true FA by using tests for normality, directional asymmetry, antisymmetry and difference from the interindividual variations. The results showed no correlation between FA (either signed or absolute) and heterozygosity, body size and SMS, while heterozygosity was clearly positively correlated with body size and with SMS. Our data suggest an effect of the presence of some particular alleles on SMS, instead of an effect of the multilocus heterozygosity, even if the presence of only three polymorphic loci weakens the conclusions. Finally, no correlation was found between body size and SMS." (Authors)] Address: Carchini, G., Dipartimento di Biologia, Università 'Tor Vergata', Via della Ricerca Scientifica, I-00133, Roma. Italy. E-mail: carchini@uniroma2.it

2078. Cashatt, E.D.; Vogt, T.E. (2001): Description of the larva of *Somatochlora hineana* with a key to the larvae of the North American species of *Somatochlora* (Odonata: Corduliidae). *Int. Jour. Odonatology* 4(2): 93-105. (in English). ["A detailed description of the final stadium of *Somatochlora hineana*, with brief notes on the penultimate stadium, is presented. An illustration of the entire larva and separate line drawings of the labium and dorsal and lateral views of the abdomen are also included. The habitat of the larva is discussed briefly. Combinations of diagnostic characters are used for distinguishing the *S. hineana* larva from its allied congeners.[...]" (Authors)] Address: Cashatt, E.D., Zoology Section, Illinois State Museum Research and Collection Center, 1011 East Ash, Springfield, IL 62703, USA. E-mail: cashatt@museum.state.il.us

2079. Chivers, D.; Mirza, R.S. (2001): Importance of predator diet cues in responses of larval wood frogs to fish and invertebrate predators. *Journal of Chemical Ecology* 27(1): 45-51. (in English). ["We examined the effects of predator diet on the antipredator responses of larval woodfrogs (*Rana sylvatica*). We found that tadpoles showed stronger responses to fish (*Perca flavescens*) than were fed tadpoles than those fed invertebrates. Similarly, we found that tadpoles responded more strongly to larval dragonflies (*Anax* spp.) fed tadpoles than to dragonflies fed invertebrates. The overall intensity of response of tadpoles to fish was much stronger than that to dragonflies. Predator diet effects are not ubiquitous in predator-prey systems. We discuss possible reasons why predator diet effects are seen in some, but not all, predator-prey systems." (Authors)] Address: Chivers, D., Department of Biology, University of Saskatchewan, 112 Science Place, Saskatoon, Saskatchewan, S7N 5E2. Canada. E-mail: doug.chivers@usask.ca

2080. Clausnitzer, H.-J. (2001): Auswirkungen von Naturschutzmaßnahmen auf Libellen und Lurche: Ökologische Verbesserung an Bächen durch Rückbau von Teichen. *Natur und Landschaft* 76(4): 145-151. (in German with English summary). ["In the basin of the Lutter, a small river in Lower Saxony (Germany), three large fishpond areas through which the river flows were converted with the aim of ecological restoration of the river. Two former fishpond areas are developing into oligotrophic spring fens; the river flows through these. It does not flow through the third former fishpond area; here, after the removal of dams, small pools, ponds and ephemeral waters have resulted. The article describes the effects of these measures on amphibians and dragonflies. All previous amphibian species are still present, but *Bufo bufo* is not expected to have much breeding success in the future. *Rana esculenta* is also reproducing less. On the other hand, *Rana temporaria* is profiting from the modification, with increasing populations. As concerns dragonflies, in the two oligotrophic fens seven widespread and frequent species have decreased or disappeared, while seven stenoeicous species of swamps and springs have settled. In the third area, with new habitats formed by ponds and pools, there have been only two new species settlements, while four species have disappeared. The removal of the commercial fishponds in the river basin has had positive ecological effects in total, as rare habitats have developed for stenoeicous and endangered species. Losses are limited to euryoeicous and therefore widespread species." (Author) Populations of *Ceragrion*

tenellum, *Orthetrum coerulescens*, *Sympetrum pedemontanum*, *Coenagrion hastulatum*, and *Aeshna juncea* increased, populations of *Lestes viridis*, *Erythromma najas*, *Aeshna mixta*, and *A. grandis* decreased. *Calopteryx splendens*, *C. virgo*, *Cordulegaster boltonii*, *Lestes dryas*, *Sympetrum flaveolum*, *Ischnura pumilio*, and *Libellula depressa* are new.] Address: Clausnitzer, H.-J., Eichenstr. 11, D-29348 Eschede, Germany.

2081. Clausnitzer, V. (2001): Notes on *Trithemis bifida* and *T. donaldsoni* (Odonata: Libellulidae). *Int. Jour. Odonatology* 4(2): 107-117. (in English). ["*Trithemis bifida* is reported for the first time from East Africa. Previously there were only two Afrotropical records of this species: one male from Zambia and one male from the Ivory Coast. The male of *T. bifida* is described and compared with the closely related *T. donaldsoni* which is also found in East Africa. Taxonomically relevant structures are figured, differential features between both species are described and notes on the ecology of *T. bifida* are given."(Author)] Address: Clausnitzer, Viola, Liebenauer Str. 180, D-06110 Halle/Saale, Germany. 2082. Cleto, F.S.E.N.; Walker, I. (2001): Efeitos da ocupação urbana sobre a macrofauna de invertebrados aquáticos de um igarapé da cidade de Manaus/AM - Amazonia central. *Acta Amazonica* 31(1): 69-89. (in Portuguese with English summary). ["Effects of urban occupation on the aquatic macroinvertebrates from a small stream of Manaus, Amazonas State, Brazil. - Conditions of water quality and of the invertebrate fauna in the stream Mindu, originating in undisturbed forest area and crossing the city of Manaus/AM, were studied from 1993 to 1995. Deforestation and invasive colonization along the headwater streams and pollution in the city center caused drastic alterations of the limnological and faunistic conditions. Thus, water temperature, conductivity, pH values and quantity of sediments in suspension rose significantly, while oxygen levels dropped. Together with the natural reduction of flow speed and increased solar radiation these alterations resulted in eutrophication and a marked change of the composition of the invertebrate fauna." (Authors)] Address: Cleto, F.S. & Walker, Ilse, INPA/CPEC/PPG, Manaus, AM, Brasil, E-mail: sergiocleto@bol.com.br, iwalker@inpa.gov.br

2083. Córdoba-Aguilar, A. (2001): Sperm displacement ability in the damselfly *Calopteryx haemorrhoidalis asturica* Ocharan: no effect of male age, territorial status, copulation duration and syn-copulatory behaviour (Zygoptera: Calopterygidae). *Odonatologica* 30(4): 375-380. (in English). ["During copulation and before sperm transfer, odonate males are able to manipulate rival sperm stored in the 9 sperm storage organs (usually the bursa copulatrix and spermathecae). Males of the territorial *C. h. asturica* use 2 mechanisms for this. Bursal sperm is removed physically whilst spermathecal sperm is displaced via aedeagal stimulation (through a series of abdominal flexions) of the female sensory system that controls spermathecal sperm ejection. Most bursal sperm is removed but there is individual variation in spermathecal sperm displacement. Previous results have found that this variation is related to aedeagal width. In this paper 4 variables that may also explain variation in spermathecal sperm displacement ability are investigated: Male age and status (territorial and nonterritorial), duration of the sperm displacement sta-

ge and the number of aedeagal stimulatory flexions. Variation in the ability to displace spermathecal sperm, however, was not related to these variables. This suggests that variation in this ability is reliant only on <J genitalic attributes, aedeagal width. These results are briefly discussed in terms of current theory of sexual selection as the process propelling genitalic evolution." 2086. Couteyen, S.; Papazian, M. (2001): Contribution à la connaissance des Odonates de l'île de la Réunion 4. *Sympetrum fonscolombii* (Selys, 1840), une espèce nouvelle pour l'île (Odonata, Libellulidae). *Martinia* 17(2): 51-53. (in French with English summary). [*S. fonscolombii* has recently been discovered in La Réunion at app. 2000 a.s.l. The presence of this species on this island proves that it is able to colonize high altitude tropical regions.] Address: Couteyen, S., 188 chemin Nid Joli, F-97430 Le Tampon, La Réunion, France

2087. Curio, E. (2001): Wie Vögel ihr Auge schützen: Zur Arbeitsteilung von Oberlid, Unterlid und Nickhaut. *Journal für Ornithologie* 142: 257-272. (in German with English summary). ["Birds close their eyes during sleep in various taxon-specific ways. Either the lower lid moves up as in the majority of species including the Anseres, Accipitres, Falconiformes, Galli, Charadriodea, Columbiformes, and Oscines; or the upper lid moves down (Psittaciformes, Trochili), or both lids close the eye as in

Strigiformes and Caprimulgi. Such information is absent for most orders, or the handbooks provide wrong or conflicting information. Beside the tonic, sleep-related eye closure, birds move one or both lids in a phasic, usually swift mode when awake. These frequent lid movements are typified by their different co-ordination and function. Photographic and observational evidence strongly suggests mechanical protection of the eye as a novel function (where this had not been proposed previously). When an impact from any object is imminent from in front of or above the head, the upper lid shuts in pigeons, owls and oscines, and with water splashing, the lower lid as well (Cinclus). The most convincing evidence for mechanical protection comes from the deployment of the upper lid during the picking up of spiny insect prey as compared to easy-to-swallow berries, when both lids stay at rest (*Gallucolumba*). [...] In fig. 1 a black and white drawing shows a Negro Bleeding-heart Pigeon (*Gallucolumba keayi*) from the Philippines picking up a dragonfly. Closure of the eye with the upper lid in response to imminent mechanical impact (after Curio et al. 2000, see OAS 2019), where alternatively, the picking up of a berry with open eyes is documented.] Address: Curio, E., Conservation Biology Unit, Ruhr-Universität Bochum, PF 102148, 44780 Bochum, Germany. Email: Eberhard.curio@ruhr-uni-bochum.de

2088. d'Aguiar, J. (2001): Les descriptions originales des Odonates d'Europe 7. Sulzer, Johan Heinrich (1735-1813). *Martinia* 17(2): 69-74. (in French with English summary). [Faksimiles of Johan Heinrich Sulzer's descriptions of *Pyrrhosoma nymphula* and *Sympetrum danae* are published and shortly commented.] Address: d'Aguiar, J., 7, rue Adrien Lejeune, F-93170 Bagnolet, France

2089. Danielzik, J. (2001): FFH-Umsetzung in Nordrhein-Westfalen aus Sicht der Entomofaunistik. - Situationsanalyse zur Realisierung der Fauna-Flora-Habitat-Richtlinie. *Naturschutz und Landschaftsplanung* 33(11): 344-350. (in German with English summary). ["The study examines the FFH site proposals in the Federal State of North Rhine-Westphalia (NW), Germany to the European network of conservation areas "Natura 2000". After introducing faunistic characteristics and investigation methods of the sites the paper illustrates why the 490 FFH site proposals and the 15 International Bird Areas are assessed as insufficient from a nature conservation point of view as regards the insects according to Appendix II of the Habitats Directive (34 species in Germany, 11 in NW). [...] The present scientific knowledge of the distribution and ecology of the species needs urgent improvement as well as the quality of the data, which are partly difficult to access." It is said that only *Coenagrion mercuriale* and *Leucorrhinia pectoralis* occur in NW; their habitat requirements and threats are shortly outlined.] Address: Danielzik, J., Auf der Kämpe 11, D-46244 Bottrop, Germany. E-mail: daejd@gmx.de

2090. De Marmels, J. (2001): *Aeshna* (*Hesperaeschna*) *condor* sp. nov. from the Venezuelan Andes, with a redescription of *A. (H.) joannisi*, comments on other species, and descriptions of larvae (Odonata: Aeshnidae). *Int. Jour. Odonatology* 4(2): 119-134. (in English). ["*Aeshna* (*Hesperaeschna*) *condor* sp. nov. is described and illustrated from four males and six exuviae. The adult color pattern does not resemble that of any other Venezuelan species, but structurally the new species

comes closest to *A. (H.) punctata* and *A. (H.) joannisi*. This latter is here recorded for the first time from Venezuela, and its exuviae are described. The larva of *A. (Marmaraeschna) vigintipunctata* is also described and figured. A key to the ultimate instar larvae of all aeshnids found in the region of the upper Rio Quinimari, Tachira State, Venezuela, is presented." (Author)] Address: De Marmels, J., Inst. Zool. Agricola, Fac. Agronomia, Univers. Central de Venezuela, Apdo. 4579, Maracay 2101, Edo. Aragua, Venezuela. E-mail: demarmjc@hotmail.com

2091. De Marmels, J. (2001): *Sympetrum paramo* sp. n. (Odonata: Libellulidae) from the Venezuelan high Andes, with a key to the species of *Sympetrum* Newman, 1833 found in Venezuela. *Entomotropica* 16(1): 15-19. (in English with Spanish summary). ["The new species is described and illustrated on the basis of four males and one female (holotype cf. Venezuela: Merida State, Sierra Nevada National Park, Paramo El Tisure, Laguna Tisure, 3 650 m, 29.XII.1994; MIZA). Diagnostic characters are the strongly developed first white lateral thoracic stripe, the dark tibiae and the checkered abdominal pattern. A key to adults of all species of *Sympetrum* found in Venezuela is provided. The difference at the species level between *S. illotum* (Hagen) and *S. gilvum* (Selys) is confirmed and illustrations of important features of both are given." (Author)] Address: De Marmels, J., Inst. Zool. Agricola, Fac. Agronomia, Univers. Central de Venezuela, Apdo. 4579, Maracay 2101, Edo. Aragua, Venezuela. E-mail: demarmjc@hotmail.com

2092. Donath, H. (2001): Erstnachweis der Feuerlibelle (*Crocothemis erythraea* (Brullé)) in der Niederlausitz. *Biologische Studien, Luckau* 30: 56-58. (in German). [The second record of this southern species in Brandenburg, Germany (Neuer Grubensee, Bornsdorf) in June and July 2001 is documented in detail: description of habitat, field diagnostic flight behaviour, co-occurring species (including the rare *Leucorrhinia caudalis* and *L. albifrons*), and some reflections for species turn over in Brandenburg. In the past years new records represent Ethiopian or Mediterranean species (*Anax ephippiger*, *Aeshna affinis*, *Crocothemis erythraea*). Only *L. caudalis* - an Eurosiberian element of fauna - was successful to colonise the region Niederlausitz more recently. Regionally declining or even extinct species belong in general to the Eurosiberian, continental faunistic element.] Address: Donath, H., Caule Nr. 1, D-15926 Zieckau, Germany

2093. Doty, G.; Welch, A. (2001): Advertisement call duration indicates good genes for offspring feeding rate in gray tree frogs (*Hyla versicolor*). *Behavioral Ecology & Sociobiology* 49(2-3): 150-156. (in English). ["Indicator or "good genes" models of sexual selection predict that mating preferences allow females to choose mates that are genetically superior. Female gray tree frogs (*Hyla versicolor*) prefer male advertisement calls of long call duration, which can be indicators of enhanced offspring growth performance. We tested the effects of father's call duration and the presence of a caged predator (dragonfly naiad) on tadpole activity and growth in a factorial experiment, controlling for maternal and environmental effects. The effect of food availability (a repeated measure) on tadpole activity was also examined. Tadpoles responded to predator presence and to high food availability by decreasing activity and feeding.

Tadpoles exposed to a caged predator were smaller after 14 days than those exposed to an empty cage, suggesting that spending less time feeding carries the cost of reduced growth. Offspring of males with long versus short calls responded similarly to the presence of a predator. Nonetheless, offspring of long-calling males spent more time feeding than did offspring of short-calling males, except when a predator was present but no food was available. Increased time spent feeding may contribute to enhanced offspring growth and, therefore, to the indirect benefit that a female may realize by selecting a mate with long calls. However, because the behavioral differences depended on the environment, and because the fitness consequences of such behavioral differences should also vary with the environment, the benefit of mating with a long-calling male may depend on the conditions encountered by the offspring." (Authors)] Address: Doty Grace & Welch Allison, Department of Biology, University of North Carolina, Coker Hall, Chapel Hill, NC, 27599-3280, USA. E-mail: welcha@unc.edu

2094. Dronzikova, M.V. (2001): "Life cycles of separate species of dragonflies in conditions of Kuznetskoi valley". *Belyshevia* 1(1): 6-9. (in Russian with short English summary). [Life cycles of *Libellula quadrimaculata*, *Sympetrum flaveolum*, *Aeshna viridis*, *Orthetrum cancellatum*, *Coenagrion hastulatum*, and *Leucorrhinia pectoralis* were studied in the Altai-Sajan mountains, Russia.] Address: Dronzikova, M.V., Novokuznetskii Pedagogicheskii Institut, 654000 Novokuznetsk, PR., Pionerskii, 13, Russia

2095. Ellenrieder, N. von (2001): A synopsis of the Patagonian species of the genus *Aeshna* Fabricius (Anisoptera: Aeshnidae). *Odonatologica* 30(3): 299-325. (in English). ["This synopsis includes diagnoses for adults, a key for male and female, illustrations of taxonomic characters and updated distribution data for each sp. The ventral terga contour is found to vary interspecifically allowing identification of all species. Other useful characters are the presence or absence of black stripes over frontoclypeal and fronto-ocular grooves, abdominal colour pattern and shape of the cerci. Some colour characters of *A. variegata* vary geographically and two forms are described: a dark (humid biomes) and light form (dry biomes). The synonymy of *A. peralta* and *A. variegata* is considered doubtful." 2097. Englund, R.A. (2001): Long-term monitoring of one of the most restricted insect populations in the United States, *Megalagrion xanthomelas* (Selys-Longchamps), at Tripler Army Medical Center, Oahu, Hawaii (Zygoptera: Coenagrionidae). *Odonatologica* 30(3): 255-263. (in English). ["Long-term monitoring of a remnant population of *M. xanthomelas*, located at Tripler Army Medical Center (TAMC) began in May 1997 and continued to Febr. 2000 for the mitigation ponds and June 2000 for the TAMC stream. This sp. has been reduced to little more than 100 m of stream habitat on Oahu at the TAMC. Threats to *M. xanthomelas* include alien fish spp., stream dewatering, and habitat alteration. The TAMC stream now requires augmented water flow because construction of a facility up gradient of the TAMC stream disrupted the normal hydrology of the small stream. The Oahu race of *M. xanthomelas* will soon become extinct if the stream were allowed to become dry, as nearly happened in June 1997. The most cost-effective way to ensure the survival of this sp. on Oahu would be to continue some mitigation water flows to the TAMC stream. The next step would be the establishment of another wild population to a stream lacking alien fish spp. It is highly recommended that a cooperative association of biologists from the Bishop Museum, University of Hawaii, U.S. Fish and Wildlife Service, and U.S. Army environmental staff continue to monitor the population of *M. xanthomelas*, arguably the rarest insect population in the United States." 2099. Fincke, O.M.; Hadrys, H. (2001): Unpredictable offspring survivorship in the damselfly, *Megaloprepus coerulatus*, shapes parental behavior, constrains sexual selection, and challenges traditional fitness estimates. *Evolution* 55(4): 762-772. (in English). ["Evolutionary biologists typically assume that the number of eggs fertilized or developing embryos produced is correlated with an individual's fitness. Using microsatellite markers, we document for the first time estimates of realized fitness quantified as the number of offspring surviving to adulthood in an insect under field conditions. In a territorial damselfly whose males defend tree hole oviposition sites, patterns of offspring survivorship could not be anticipated by adults. Fewer than half of the parents contributing eggs to a larval habitat realized any reproductive success from their investment. The best

fitness correlate was the span over which eggs in a clutch hatched. Among parents, female fecundity and male fertilization success were poor predictors of realized fitness. Although body size was correlated with female clutch size and male mating success, larger parents did not realize greater fitness than smaller ones. The uncoupling of traditional fitness surrogates from realized fitness provides strong empirical evidence that selection at the larval stage constrains selection on mated adults." 2100. Fossati, O.; Wasson, J.-G.; Hery, C.; Salinas, G.; Marin, R. (2001): Impact of sediment releases on water chemistry and macroinvertebrate communities in clear water Andean streams (Bolivia). *Archiv für Hydrobiologie* 151(1): 33-50. (in English). ["The impact of sediment releases due to road construction on water chemistry and invertebrate communities was studied in a clear water river system in the tropical humid Bolivian Andes. Eight sites (2 reference, 1 source and 5 impacted along the main river) were sampled during the 1997 low flow season. Suspended sediment concentrations exhibited a 500-fold increase downstream from the source of pollution compared to the reference site, but recovered to natural levels within 90km in the main river. Suspended solids had only a minor influence on other chemical parameters, but had a clear negative effect on invertebrate density (200-fold decrease in abundance) and diversity (6-fold decrease in number of taxa) in the main river. The most affected insects were epibenthic gatherers (e. g. Ephemeroptera: Leptohyphidae, Coleoptera: Elmidae), swimmers (Ephemeroptera: Leptophlebiidae), and scrapers (Coleoptera: Psephenidae, Trichoptera: Hydroptilidae). These families are therefore considered to be the best potential bio-indicators of sediment release impact in clear-water Andean rivers." (Authors) The density of Odonata ("Libellulidae, Gomphidae") in the streams surveyed is very low.] Address: Fossati, Odile, Institut de Recherche pour le Developpement (IRD) - Université Lyon 1, Ecologie des Hydrosystemes fluviaux, 43 Bd du 11 novembre 1918, 69622 Villeurbanne Cedex, France. - E-mail: j.o.fossati@wanadoo.fr

2101. Gaino, E.; Reborá, M. (2001): Apical antennal sensilla in nymphs of *Libellula depressa* (Odonata: Libellulidae). *Invertebrate Biology* 120(2): 162-169. (in English). ["In an ultrastructural study of the apical antenna of the last nymphal stages of *L. depressa*, we found long sensilla trichodea, 2 sensory pegs, and a coeloconic sensillum on the last article of the flagellum (the distal part of the antenna). The long sensilla trichodea are mechanoreceptors, almost identical to the long filiform hairs of some terrestrial insects and the first sensilla of this kind to be described in aquatic insects. Particular attention was given to the complex coeloconic sensillum, a compound sensillum innervated by 2 groups of 3 neurons wrapped in a dendritic sheath. A cuticular sleeve envelops the distal portion of the outer dendritic segment. The cuticle of the coeloconic sensillum shows wide channels and is contiguous to the underlying granular and fibrillar layer. Similar structures on the antennae of the adults of other dragonflies were identified as chemoreceptors in previous studies. We hypothesize that this larval coeloconic sensillum might likewise have a chemosensory function, responding to molecules that diffuse through the cuticle and the un-

derlying granular and fibrillar layer, as no clear pore or pore-tubule system is visible. Alternative functions are also explored on the basis of morphological details." 2102. Gallie, J.A. ; Mumme, R.L.; Wissinger, S.A. (2001): Experience has no effect on the development of chemosensory recognition of predators by tadpoles of the American toad, *Bufo americanus*. *Herpetologica* 57(3) : 376-383. (in English). ["Although chemosensory recognition of predators by larval amphibians is well known, the extent to which experience plays a role in the development of this anti-predator behavior is unclear. We addressed this issue by exposing laboratory-reared (naive) and wild-caught (experienced) tadpoles of the American toad, *Bufo americanus*, to water-borne chemical cues of three different potential predators (bluegill sunfish, *Lepomis macrochirus*, larvae of the odonate *Anax junius*, and adults of the red-spotted newt, *Notophthalmus viridescens*). Compared to control tadpoles exposed to dechlorinated water, tadpoles exposed to chemical cues of *Lepomis* and *Anax* significantly decreased activity and significantly increased aggregation. However, the behavior of tadpoles exposed to chemical cues of *Notophthalmus* was identical to that of control tadpoles. Most importantly, we found no difference in anti-predator behavior between laboratory-reared and wild-caught tadpoles. We conclude that larval experience with predators is unnecessary for the development of chemosensory predator recognition and that anti-predator behavior in this species is largely innate." thors)] Address: Gonzalez-Soriano, E., Depto Zoologia, Inst. Biol., Universidad Autonoma, Apartado Postal 70-153, 04510 Mexico, D.F., Mexico. E-mail: esoriano@mail.ibiologia.unam.mx

2106. Gonzalez-Soriano, E. (2001): An unusual male aggregation in the Odonata: An aerial mating swarm in *Protoneura cara* Calvert and notes on other Mexican Protoneuridae (Zygoptera). *Odonatologica* 30(3): 335-340. (in English). ["On several occasions aggregations were seen hovering high among trees beside streams in Mexico. Intermittent arrival of conspecific females at some aggregations and their departure, sometimes in tandem, and the apparent absence of foraging within aggregations supports the inference that such aggregations are mating swarms. It remains to be discovered whether trees over which swarms form are potential oviposition sites for this sp., or are places in which both males and females overnigh. Flying aggregations of males in other spp. of Protoneuridae are described and discussed." (Author)] Address: Gonzalez-Soriano, E., Depto Zoologia, Inst. Biol., Universidad Autonoma, Apartado Postal 70-153, 04510 Mexico, D.F., Mexico. E-mail: esoriano@mail.ibiologia.unam.mx

2107. Gossum, H. van; Stoks, R.; De Bruyn, L. (2001): Reversible frequency-dependent switches in male mate choice. *Proceedings of the Royal Society Biological Sciences Series B* 268(1462): 83-85. (in English). ["Current sexual-selection theories predict that mating should occur preferentially with the highest-quality partner, and assume that for distinguishing among potential mates the choosy sex applies an internal representation of the characteristics of the desired mate, i.e. a template. Binary choice experiments were performed to test male mate choice between two different female colour morphs in the damselfly *Ischnura elegans*. Choice experiments were conducted before and after an habituation period, during which males were exposed to only one female colour morph. Given the choice between the two female morphs, males did exhibit a choice for the most recently experienced female morph. This is the first evidence for a reversible switch in mate choice in a frequency-dependent way. In contrast with previous studies on mate choice, template formation in male *I. elegans* seems not to be based on quality. Switching mate choice in a frequency-dependent manner, choosing the most common morph, probably allows males to minimize their search efforts and to maximize fitness." 2110. Hampton, S.E.; Gilbert, J.J. (2001): Observations of insect predation on rotifers. *Hydrobiologia* (446-447): 115-121. (in English). ["Interactions between rotifers and their insect predators have not received adequate attention, possibly due to the assumption that rotifers are too small for insects to eat. In laboratory experiments, we offered the rotifers *Hexarthra mira*, *Platinius patulus* and small and large *Synchaeta pectinata* to four common insect predators: the notonectids *Notopecta lunata* and *Buenoa macrotibialis*, the smaller hemipteran *Neoplea striola* and small (1.5 mm) aeshnid dragonfly larvae. Excepting *Platinius* offered to dragonflies, all rotifer preys were consumed to some degree. No size selectivity was apparent for predators that ate few rotifers, but small instar *Buenoa* ate significantly more large (420 µm) than small (300 µm) *Synchaeta*. Predator size appeared to be less important than predatory style and prey morphology in determining ingestion rates. *Neoplea* and dragonflies ate more *Hexarthra* than *Platinius*, while the pattern was reversed for *Buenoa*, possibly because *Buenoa* is able to manipulate the hard lorica of *Platinius* better. Insect predators are capable of direct suppression of rotifer populations, an interaction which may be particularly important in littoral zones and fishless ponds where macroinvertebrates are numerous." (Author)] Address: Hampton, Stephanie, Department of Biological Sciences, Dartmouth College, 6044 Gilman, Hanover, NH, 03755-3576, USA. 2111. Hansen, M.D. (2001): Mass occurrence and migration of *Libellula quadrimaculata* at the Skaw Peninsula, N Jutland, Denmark in 2000. *Flora og Fauna* 107(1): 22-26. (in Danish with English summary). ["During May and June 2000 *L. quadrimaculata* was extremely common at the Skaw Peninsula in northern Jutland, Denmark. A sudden, massive emergence from the small, shallow lakes (water-covered area >1 km²) on the peninsula took place on May 8, after a long period of hot and sunny weather conditions. The density of larval exuviae in this area was estimated to exceed 1 m², and on May 14, more than 3000 stationary dragonflies were recorded in a 300 m transect count. At the northernmost coastline of the peninsula, migrations took place during the period May 12-16, with a pronounced peak on May 16 when thousands of dragonflies migrated towards west against a light westerly breeze. Four 1-minute counts were performed, and the mean density was estimated to 160 migrating *L. quadrimaculata* per 50 meter front per minute. As the width of the migratory wave was approx 500 meters, it can be calculated that, on this day, almost 100.000 *L. quadrimaculata* per hour migrated towards west on the Skaw Peninsula. Although the species was still very common during the following weeks, no further migrations were recorded, probably due to cold and windy weather conditions. These observations are discussed in relation to the migration ecology of the species." (Author)] Address: Han-

2112. Heino, J. (2001): Regional gradient analysis of freshwater biota: Do similar biogeographic patterns exist among multiple taxonomic groups? *Journal of Biogeography* 28(1): 69-76. (in Danish with English summary). ["Aim: To examine if different groups of freshwater organisms show concordant distribution patterns at large spatial scales. Location: Northern Europe: Denmark, Sweden, Norway, Finland. Methods: I analysed provincial distribution records of macrophytes, dragonflies, stoneflies, dytiscid beetles and teleost fishes in northern Europe. I conducted multivariate analyses, including two-way indicator species analysis (TWINSPAN), canonical correspondence analysis (CCA) and Mantel test to reveal biogeographical patterns and the degree of concordance in the distribution patterns among taxa. Results: TWINSPAN and Mantel tests indicated that broadly similar biogeographical patterns existed among the taxonomic groups. The results of CCA confirmed that variation in provincial species composition was generally related to climatic variation along latitudinal and altitudinal gradients. However, variation partitioning revealed that less than 50% of variation in the distribution patterns of each taxonomic group was accounted for by the climatic and geographical variables. Main conclusions: The distribution patterns of most taxonomic groups were strongly concordant and related to provincial climate and geographical location. Such patterns suggest that large-scale factors determine not only provincial species combinations, but also express severe constraints on the composition of local communities. Therefore, these factors should also be considered in studies on the structure and conservation of local freshwater systems. [...] Dragonflies: Data for the distribution of dragonflies were derived from Askew (1988) and references therein. Although less accurate than the maps for macrophytes, these distribution maps are based on relatively good north European literature. Original data were transformed to provincial records. Altogether 56 species of dragonflies were regarded as having breeding populations in the area." (Author)] Address: Heino, J., Department of Biology, University of Oulu, 90401, Oulu, Finland. 2113. Hero, J.-M.; Magnusson, W.E.; Rocha, C.F.D.; Catterall, C.P. (2001): Antipredator defenses influence the distribution of amphibian prey species in the central Amazon Rain Forest. *Biotropica* 33(1): 131-141. (in English with Portuguese summary). ["The high diversity of amphibians in the central Amazon Rain Forest allowed us to examine the influence of tadpole antipredator defenses on assemblage structure and composition within bodies of water (alpha diversity) and among aquatic sites (beta diversity) at a local scale. During a three-year study of tadpole assemblage composition, we found that the anuran community used a variety of bodies of water for reproduction; these ranged from streams and streamside ponds to isolated forest ponds. The distribution of several tadpole species was negatively related to fish density, while other species coexisted with high densities of fish. Tadpole size did not ensure survival against fish, and few tadpoles avoided fish by hiding in the leaf litter. Controlled predation experiments using a single tadpole species in a no-choice situation were conducted over 24- to 48-hour periods. Nearly all species of tadpoles that occurred in habitats

with high fish densities were unpalatable to fish (except *Centrolenella oyampiensis*), indicating that unpalatability is a major adaptation allowing tadpoles and fish to coexist in this system. Unpalatability (to fish), however, was not an effective antipredator defense against odonate larvae, the other major tadpole predator in this system. The combination of predation pressure and the antipredator traits exhibited by individual species largely determined the composition of tadpole assemblages in individual bodies of water (alpha diversity). The heterogeneous distribution of predators among bodies of water and the diversity of antipredator defenses exhibited by larval amphibians facilitated high diversity in this community (beta diversity)." 2116. Hopkinson, P.; Travis, J.M.J.; Evans, J.; Gregory, R.D.; Telfer, M.; Williams, P.H. (2001): Flexibility and the use of indicator taxa in the selection of sites for nature reserves. *Biodiversity & Conservation* 10(2): 271-285. (in English). ["'Minimum' sets of complementary areas represent all species in a region a given number of times. In recent years, conservation assessments have centred around the evaluation of these 'minimum' sets. Previous research shows little overlap between 'minimum' sets and existing nature reserves and between 'minimum' sets for different taxonomic groups. The latter has been used as an argument to discount the use of indicator taxa in the selection of sites for nature reserves. However, these 'minimum' set analyses have only considered a single set for each taxonomic group when there are, in fact, a large number of equally valid 'minimum' sets. We present new methods for evaluating all of these alternative 'minimum' sets. We de-

monstrate that if all of the sets are evaluated, significantly higher levels of overlap are found between 'minimum' sets and nature reserves, and pairs of 'minimum' sets for different taxonomic groups. Furthermore, significantly higher proportions of species from non-target taxonomic groups are recorded in the 'minimum' sets of target groups. Our results suggest that previous conservation assessments using 'minimum' sets may have been unduly pessimistic." 2117. Hopper, K.R (2001): Flexible antipredator behavior in a dragonfly species that coexists with different predator types. *Oikos* 93(3): 470-476. (in English). ["Two of the main predators of dragonfly larvae, insectivorous fish in communities with fish and large dragonfly species in communities without fish, differ markedly in their mode of predation. In general, dragonfly species coexist successfully with one predator or the other, but larvae of the dragonfly *Pachydiplax longipennis* can coexist successfully with both. I examined the behavioral response of these larvae to a simulated predator attack to determine whether their response (1) differs between the two communities, and (2) is sensitive to waterborne cues about the type of predator present. I compared larvae from two different communities: fish ponds where insectivorous fish were the top predators, and fish-free ponds where large dragonflies were the top predators. Larvae from fish-free ponds actively moved away from an attack significantly more than did larvae from fish ponds, provided each was attacked in its native pond water. Larvae collected from a fish-free pond but then attacked in fish water moved less than did controls (larvae attacked in fish-free water). Likewise, larvae collected from a fish pond but attacked in fish-free water moved more than did controls (larvae attacked in fish water). Larvae attacked first in water from their native pond and then in water from the contrasting pond changed their response in the expected direction. These results indicate that escape behavior in *P. longipennis* differs between communities with different predator types and is sensitive to water-borne cues in a manner consistent with the mode of predation employed by each predator." (Author)] Address: Hopper, K.R. Biological Sciences, Univ. of Kentucky Lexington Community College, Lexington, KY, 40506-0235, USA. E-mail: hopper@pop.uky.edu

2118. Hostettler, K. (2001): Libellen (Odonata) in Vorarlberg (Österreich). *Vorarlberger Naturschau* 9: 9-134. (in German with English summary). ["In 1991 the first mapping of dragonflies for Vorarlberg was started at the Rhine delta. In the course of the subsequent eight years, in collaboration with the Vorarlberger Naturschau, it was extended to the other regions of this mountainous region. At nearly 336 habitats 55 species of dragonflies were recorded. 49 species were found in the valley and 37 species in mountainous at subalpine altitudes. In particular the large populations of *Sympetma paedisca* and *Sympetrum depressiusculum* in the Rhine delta at the Lake of Constance have to be mentioned, but also the relatively good presence of *Somatochlora alpestris*, *Orthetrum coerulescens*, *Aeshna caerulea*, *Leucorrhinia dubia*, and *Cordulegaster bidentata* at certain altitudes and regions." Each species is characterised in a monographic way containing a map of its regional distribution, and information

on habitat and ecology, threat and protective measures. "For the first time a red list of the endangered species of dragonflies is provided for Vorarlberg. Finally some types of habitats (mires, flowing waters) and their dragonfly fauna are presented." (Author) This paper also includes a short introduction into dragonfly biology and some nice colour photographs of species and habitats.] Address: Hostettler, K., Schulstr. 7, CH-8590 Romanshorn, Switzerland

2119. Hunger, H.; Röske, W. (2001): Short-range dispersal of the Southern Damselfly (*Coenagrion mercuriale*, Odonata) defined experimentally using UV fluorescent ink. *Zeitschrift für Ökologie und Naturschutz* 9: 181-187. (in English with German summary). [Specimens of *C. mercuriale* were marked with numbers and with a dot of UV fluorescent ink. At night "controls with a portable UV-lamp allowed high recapture rates. Only few individuals, however, were recaptured in study sites different from the ones where they had been marked. The maximum distance covered by an individual was 300 m. [...] this means that protective measures with the aim of preventing further habitat fragmentation are of extreme importance for *C. mercuriale* as one of the most endangered Odonata species of Central Europe." (Authors)] Address: Hunger, H., Institut für Naturschutz und Landschaftsanalyse (INULA), Am Pfahlgraben 8, D-79276 Reute, Germany

2120. InsectLine (2001): Insects reported during April and July 2001. *Atropos* 14: 33-35. (in English). ["[...] Dragonfly immigration was also low-key. Single Red-veined Darter *Sympetrum fonscolombei* were reported at Heysham, Lancashire (also seen the next day), and near Tring, Hertfordshire, on 6th. Reports also came from some of the suspected West Country breeding sites later in the month, but all in very low numbers and more suggestive of immigration. Single Lesser Emperor *Anax parthenope* were at the Middleton Industrial Estate, Lancashire, and Dungeness RSPB, Kent, on 23rd, Marazion Marsh RSPB, Cornwall, from 28th with one nearby on the Lizard the following day. A Small Red-eyed Damselfly *Erythromma viridulum* was reported at Sizewell, Suffolk, on 31st. 2121. Johansson, F.; Stoks, R.; Rowe, L.; De Block, M. (2001): Life history plasticity in a damselfly: Effects of combined time and biotic constraints. *Ecology* 82(7): 1857-1869. (in English). ["Optimal values for life history traits are expected to depend upon environmental conditions during development and the period within which development is constrained (e.g., biotic factors and time constraints, respectively). Theory predicts that life history responses to both biotic factors and time constraints may be both direct and behaviorally mediated. Few experimental studies of life histories have considered the joint effects of biotic factors and time constraints, and fewer still have been able to disentangle direct from behaviorally mediated effects. We studied such interactions by manipulating the perceived time to the onset of winter, predation risk, and food resources level in larvae of the damselfly *Lestes sponsa*. In the first experiment (predation X time constraint), the presence of a predator caused an overall reduction in foraging activity, development rate, and mass at emergence. However, larvae that had less time available before the end of the season, increased foraging activity and development

rate, while mass at emergence decreased. These results suggest that the observed changes in life history characters were behaviorally mediated in the presence of predators. In contrast, life history responses of time-constrained larvae occurred independently of the behavioral changes and, therefore, were direct. In the second experiment (food level X time constraint) larvae under high food levels had a higher foraging activity, increased development rate, and higher growth rates, compared to low food-level treatments. Time-constrained larvae accelerated development and had a smaller mass at emergence at high food levels than larvae that were not time constrained. In contrast, and opposite to predictions, time-constrained larvae at low food levels had the slowest development rate and the largest mass at emergence. We suggest that larvae in the latter group were aiming to delay emergence to the next season (cohort splitting). Our results suggest that both behaviorally mediated and direct responses to biotic factors and time constraints are a feature of the life history of this damselfly." 2122. Karouna-Renier, N.K.; Sparling, D.W. (2001): Relationships between ambient geochemistry, watershed land-use and trace metal concentrations in aquatic invertebrates living in stormwater treatment ponds. *Environmental Pollution* 112(2): 183-192. (in English). ["Stormwater treatment ponds receive elevated levels of metals from urban runoff, but the effects of these pollutants on organisms residing in the ponds are unknown. We investigated the accumulation of Cu, Zn, and Pb by macroinvertebrates collected from stormwater treatment ponds in Maryland serving commercial, highway, residential and open-space watersheds, and determined whether watershed land-use classification influences metal concentrations in macroinvertebrates, sediments, and water. Three types of invertebrate samples were analyzed - molluscs, odonates, and composite. Zn concentrations in odonates from ponds draining watersheds with commercial development (mean = 113.82 $\mu\text{g g}^{-1}$) were significantly higher than concentrations in the other land-use categories. Similarly, Cu levels in odonates from commercial ponds (mean = 27.12 $\mu\text{g g}^{-1}$) were significantly higher than from highway (mean = 20.23 $\mu\text{g g}^{-1}$) and open space (mean = 17.79 $\mu\text{g g}^{-1}$) ponds. However, metal concentrations in sediments and water did not differ significantly among land-uses. The results suggest that despite the high variation in ambient metal concentrations within each land-use category, macroinvertebrates in ponds serving commercial watersheds accumulate higher levels of Cu and Zn. The levels of Cu, Zn, and Pb in invertebrates from all ponds were less than dietary concentrations considered toxic to fish." 2125. Kesel, A.B. (2001): The ultralight aerofoils of insects - an evolutionary masterpiece. *Zoology* 103: 222-229. (in English). ["The development of wings can be regarded as the key innovation in the course of insect evolution. They make locomotion in a three-dimensional space possible, a world wide spreading and the inhabitation of almost all biotopes. Due to their low mass and high stability, wings can be interpreted as ultralight aerofoils. To guarantee the enormous mechanical demands of flight, the material and its geometrical arrangement are of crucial importance. The wings are part of the cuticular exoskeleton of the insects. This cuticle is a helicoidal fibre reinforced material of crystalline biopolymers, embedded in a protein matrix. Apart from providing the necessary stability, the ingenious structure design induces excellent aerodynamic performance. The statics as well as the aerodynamic quality of the highly complex system wing are supported throughout all hierarchic levels by a series of fine structures." (Author) *Libellula depressa* has "a very conservative wing vein pattern. An encircling marginal vein, serving as mechanical protection and stiffening of the wing and, compared to other species, a complex network of smaller veins with thin membranes stretched between them."] Address: Kesel, Antonia, Department of Zoology, Technical Biology and Bionics; University of Saarland; D - 66041 Saarbrücken. - 2127.** Ketelaar, R. (2001): Verspreidingsgegevens van libellen als instrument bij het herstel van vennen. *Levende Natuur* 102(4): 166-170. (in Dutch with English summary). ["Distribution records of dragonflies as a management tool in moorland pool restauration projects. - In The Netherlands moorland pools (shallow lakes on sandy soils) are highly valuable in terms of dragonfly species diversity. However, most pools are negatively influenced by acidification, eutrofication and desiccation. Especially dragonflies of (weakly) buffered, mesotrophic, moderately acid pools have declined severely during the last century. A number of restauration plans for moorland pools have been prepared or executed in the past decade in the southern part of The Netherlands. These measures include removal of the organic top layer of both the bottom of the pool and the shore and cutting of forest and (artificially) restauration of the buffering capacity. However the ecological demands of fauna are often not taken into consideration and this sometimes result in 'fauna accidents': special fauna elements disappear. In the province of Noord-Brabant dragonfly distribution data are now available for most moorland pools, thus making it possible to take full account of dragonflies while making restauration plans. Dependent on the number of characteristic dragonfly species four scenarios for restauration are presented: If more than two characteristic dragonfly species are present: Stop restauration. If there are one or two characteristic species present: Take care while planning the restauration. If there are no characteristic species present: Continue. If there is insufficient data available: More research." (Author)] Address: Ketelaar, R., De Vlinderstichting, 6700 AM, Wageningen, The Netherlands. E-mail: robert.ketelaar@vlinderstichting.nl
- 2128.** Kilgour, R. (2001): Emperor Anax imperator predating Brimstone *Gonepteryx rhamni*. *Atropos* 14: 62. (in English). [UK, Park Corner Heath Butterfly Conservation reserve, East Sussex, 4 June 2001, "[...] Libellula depressa and an Emperor Anax imperator were also present. - 2129.** Kirkton, S.D.; Schultz, T.D. (2001): Age-specific behavior and habitat selection of adult male damselflies, *Calopteryx maculata* (Odonata: Calopterygidae). *Journal of Insect Behavior* 14(4): 545-556. (in English). ["We compared the age, movement, and time-activity budgets of male *Calopteryx maculata* damselflies occupying off-stream tree-fall gaps with those at stream sites within a 10-ha woodland. All males collected at off-stream sites were younger than males collected at stream sites-as indicated by their significantly higher wing transmittance. Thirty-three percent of teneral males marked at off-stream gaps moved to stream sites within 4 days (mean distance = 140 m), while mature males marked at stream sites never left the stream. In contrast to stream site males, off-stream males spent significantly more time capturing prey and never engaged in aggressive interactions with other males. Behavioral differences were not due to variations in the operative body temperature. However, malaise trapping revealed a greater frequency of suitable prey in forest light gaps. Our findings support the idea that teneral male *Calopteryx* leave their emergence sites along the stream for off-stream light gaps to forage without interference and build the energy reserves necessary to attain and hold streamside territories." (Authors)] Address: Schultz, T. D. Dept of Biology, Denison University, Granville, Ohio 43023, USA. E-mail: Schultz@Denison.edu

- 2133.** Kosterin, O.E.; Haritonov, A.; Inoue, K. (2001): Dragonflies of the part of Novosibirsk Province east of the Ob River, Russia. *Sympetrum Hyogo* 7/8: 24-49. (Bilingual in Japanese and English). ["An annotated list of the dragonfly fauna is presented of the part of the Novosibirsk Province situated east of the Ob River as the most interesting territory including the city, within 53° 28' - 56° 03' N and 82° 48' - 85° 10' E. and comprising the Bolotninskii, Moshkovskii, Toguchinskii, Novosibirskii, Iskitimskii, Cherepanovskii, Maslyaninskii, and Suzunskii Districts. A short sketch of natural conditions of this region is presented. 48 species are recorded. In-

formation is given on the distribution of dragonfly species over the territory considered, their biotope preferences and approximate flight periods. The fauna has in general a western appearance. 5 species (*Lestes dryas*, *Aeshna subarctica*, *A. juncea*, *Sympetrum danae*, *Libellula quadrimaculata*) have holarctic ranges, 21 species (*Lestes sponsa*, *Sympecma paedisca*, *Coenagrion armatum*, *C. johannsoni*, *C. lunulatum*, *Erythromma najas*, *Enallagma cyathigerum*, *Ischnura elegans*, *Nehalennia speciosa*, *Aeshna mixta*, *A. crenata*, *A. serrata*, *A. viridis*, *Stylurus flavipes*, *Epitheca bimaculata*, *Somatochlora metallica*, *S. arctica*, *Cordulia aenea*, *Sympetrum flaveolum*, *S. pedemontanum*, *S. vulgatum*) have Transpalearctic or nearly Transpalearctic ranges. 18 species (*Calopteryx splendens*, *Lestes barbarus*, *L. virens*, *Coenagrion hastulatum*, *C. puella*, *C. pulchellum*, *Platycnemis pennipes*, *Aeshna affinis*, *A. grandis*, *Ophiogomphus serpentinus*, *Gomphus vulgatissimus*, *Somatochlora flavomaculata*, *Leucorrhinia caudalis*, *L. pectoralis*, *L. albifrons*, *L. dubia*, *L. rubicunda*, *Sympetrum sanguineum*) have West Palearctic ranges, 4 species (*Nihonogomphus ruptus*, *Gomphus epophthalmus*, *Macromia amphigena*, *Sympetrum croceolum*) have East Palearctic ranges being distributed from the Pacific to the Ob River and found in the territory considered the western borders of their ranges. Distribution in Siberia of *Gomphus epophthalmus*, *Macromia amphigena*, and *Sympetrum croceolum* is given in detail [...]. The two former are East-Asiatic species absent (or at least extremely local) from the vast territory of East Siberia (not taking into account a very doubtful original report of *G. epophthalmus* for Irkutsk) but appear in the piedmonts of the western South Siberian mountains: in the environs of Krasnoyarsk, in North Altai, Kuznetskii Alatau, Gomaya Shoria and Salairskii Kryazh Mts. For *S. croceolum* only two localities are hitherto known in its western range: on NW Altai (Kosterin, 1987a, b, 1997b) and the SE extreme of the Novosibirsk Province (Belyshev et al., 1989) (detailed information on these two localities is given in this paper). Such a disjunctive Altai-Far Eastern range type was recently isolated for some Lepidoptera connected with nemoral forest formations. It is supposed to be exhibited by some species which acquired a continuous Siberian-Far Eastern distribution during the Climatic Optimum of the Holocene due to westward migrations but later retrived due to cooling and aridisation of the climate, leaving isolates in sufficiently moist NW part of the Altai-Sayan Mountain System (Dubatolov, Kosterin, 1998; 2000). Interesting is the fact that an in general rare species *Gomphus epophthalmus* predominates over other Gomphid species on the Inya River while *G. vulgatissimus* (so far not found in other regions in Siberia) prevails on all other rivers and rivulets. An intergeneric copulation was observed and photographed between a male *Cordulia aenea* and a female *Epitheca bimaculata*. [To assess the success of revitalisation of a running water of the town of Linz, Austria ("Sammelgerinne Urfahr"), starting in 1995 the odonate fauna of some stretches was surveyed. The following species are analysed in detail: *Calopteryx splendens*, *C. virgo*, *Platycnemis pennipes*, *Gomphus vulgatissimus*, *Ophiogomphus cecilia*, *Onychogomphus forcipatus*, and *Cordulegaster boltonii*. There was no significant difference between regulated and revitalised stretches of the running water. Ecological quality for dragonflies depends on structural diversity of the running waters and ecological processes (e.g. availability of sand or gravel banks) more than on revitalisation or not.] Address: Laister, G., Naturkundliche Station, Neues Rathaus, Hauptstr. 1-5, A-4041 Linz, Austria

2140. Lang, C.; Müller, H.; Waringer, J.A. (2001): Larval habitats and longitudinal distribution patterns of *Cordulegaster heros* Theischinger and *C. bidentata* Selys in an Austrian forest stream (Anisoptera: Cordulegastriidae). *Odonatologica* 30(4): 395-409. (in English). ["From May 1997 to April 1998 larvae were recorded at the Weidlingbach, a fourth order tributary of the Danube nr Vienna, at 12 sampling stations from source to mouth. From the 14 larval instars reported for the genus, 5 (F to F-4; based on head width) could be identified in both spp.; head widths of female larvae were significantly larger than in male. Both spp. were most abundant within medium sand sediments with a mean grain size (Q50) of 2.04 mm in *C. bidentata* and 2.79 mm in *C. heros*. Mean water depths and nose current speeds measured at larval microhabitats were 4.4 cm and 2.3 cm s⁻¹ (*C. bidentata*) and 5.6 cm and 2.6 cm s⁻¹ (*C. heros*). During the winter months larvae chose the water depths slightly deeper than during summer. Throughout the observation period, a high proportion of the larvae (*C. bidentata*: 70-100%; *C. heros*: 41-90%) were burrowed in sandy sediments, either totally or displaying the typical ambush posture with only head and anal pyramid visible. In winter, the proportion of burrowing larvae was insignificantly higher than in summer. *C. bidentata* larvae were most abundant near the sources, preferring first order stream sections (discharge 0.1 -3.21 s⁻¹) with high hardness (up to 34

German degrees) and conductivity (up to 1100 uS cm⁻¹) and a high proportion of fine sediments. Although *C. heros* larvae were also collected at such first order sites, they reached their highest abundance (larval density up to 7.84 specimens per 10 meter shore length) at second order stream sections (discharge 0.3-6.0 l s⁻¹) with lower hardness and conductivity and a higher proportion of coarse sediments." 2144. Lenders, H.J.R.; Leuven, R.S.E.; Nienhuis, P.H.; Nooij, R.J.W. de; Rooij, S.A.M. van (2001): BIO-SAFE: A method for evaluation of biodiversity values on the basis of political and legal criteria. *Landscape & Urban Planning* 55(2): 121-137. (in English). ["This paper presents a Spreadsheet Application For Evaluation of Biodiversity (BIO-SAFE) on the basis of political and legal criteria derived from national and international policy plans, laws, treaties and directives. The BIO-SAFE is developed as a management tool to optimise mutual attuning of nature conservation policies and other interests in spatial planning. Fields of application of BIO-SAFE comprise designs and evaluations of physical planning projects, environmental impact assessments and comparative landscape-ecological studies. Taxonomic groups involved in BIO-SAFE are higher plants, dragonflies and damselflies, butterflies, fish, amphibians, reptiles, birds and mammals. The development of BIO-SAFE was based on species characteristic of rivers and their floodplains, but the principles of the me-

thod can easily be applied to other ecosystems as well. The BIO-SAFE has been applied on behalf of a combined flood risk reduction and ecological rehabilitation plan for the Rijnwaarden floodplains (River Rhine, the Netherlands). Application to flora and fauna data available for this area showed that the BIO-SAFE method enables the user to express politically and legally based biodiversity values in quantitative terms and to compare biodiversity values for various taxonomic groups, landscape-ecological units (e.g. ecotopes) and physical planning scenarios. By linking habitat preferences of the species selected to ecotopes, the method also allows the user to derive relevant information at the ecosystem level. Because of its policy-based character, BIO-SAFE yields complementary information to more established ecological biodiversity indices." 2145. Leroy, T. (2001): Les Odonates des lacs-tourbières de l'Artense en Auvergne (Puy-de-Dôme et Cantal). *Martinia* 17(2): 37-50. (in French with English summary). [Between 1996 to 1999, composition and the structure in terms of frequency and abundance of the odonate fauna of 8 bog lakes of Artense, France was studied. 40 species are present, of which 34 are autochthonous. The species composition is characterised by a high degree of species typical for the peat bogs of the Massif Central (e.g. *Somatochlora arctica*, *Leucorrhinia dubia*) and a strong contingent of species not belonging to bogs, most of them of Mediterranean or Atlantic affinity (e.g. *Platycnemis acutipennis*, *Lestes v. virens*).] Address: Leroy, T., Le Bourg, F-63210 Heume-L'Église, France

2146. Leung, B.; Forbes, M.R.; Baker, R.L. (2001): Nutritional stress and behavioural immunity of damselflies. *Animal Behaviour* 61(6): 1093-1099. (in English). ["Increased mortality in the presence of stress may result from stress-reduced availability of energy for immune function, coupled with the presence of pathogens or parasites. We tested the hypothesis that stress reduces antiparasite responses of damselflies *Ischnura verticalis* (Hagen) to their ectoparasitic mites *Arrenurus pseudosuperior* (Marshall). Numbers of colonizing mites did not differ between nutritionally stressed and unstressed damselflies. However, unstressed damselflies successfully removed more attached mites than nutritionally stressed host larvae. Furthermore, certain damselfly behaviours increased in the presence of non-feeding mite larvae. Some of these behaviours were effective in defending against mites, but were reduced by nutritional stress. These results are sufficient to explain inverse relations found between damselfly condition and intensity of mite parasitism seen in nature, and are likely to be applicable to other host-ectoparasite associations." 2147. Lotzing, K. (2001): Die Plattbauchlibelle (*Libellula depressa* L.) - Insekt des Jahres 2001. *Halophila* 42: 17. (in German). [Short and general remarks on the "Insect of the Year" in Germany, *L. depressa*.] Address: Lotzing, K., Am Hollschen Bruch 4c, D.39435 Unseburg, Germany

2148. Manteifel, Y.B.; Reshetnikov, A.N. (2001): Selective predation on tadpoles of three anuran species. *Zhurnal Obshchei Biologii* 62(2): 150-156. (in Russian with English summary). ["In laboratory experiments an introduced fish *Perccottus glenii* consumed selectively tadpoles of three numerous anuran amphibian species of Moscow Province. *Perccottus glenii* actively consumed all seized tadpoles of the *Rana arvalis* and *R. temporaria*. These predators consumed significantly lesser number of *Bufo bufo* tadpoles and frequently rejected them after seizing without considerable damages. Observations showed that *P. glenii* rejects *B. bufo* after intraoral testing. Larvae of dragonfly *Aeshna cyanea* also actively consumed almost all seized *R. arvalis* tadpoles, while usually rejected *B. bufo* after attacking and damaging them. Larvae of diving beetle *Dytiscus marginalis* sucking out captured prey, intensively consumed tadpoles of *R. arvalis* and *B. bufo* and did not reject them." (Authors)] Address: Manteifel, Y.B., A. 2150. Martens, A. (2001): Initial preference of oviposition sites: discrimination between living and dead plant material in *Sympecma fusca* and *Coenagrion caerulescens* (Odonata: Libellulidae, Coenagrionidae). *European Journal of Entomology* 98: 121-123. (in English). ["*Sympecma fusca* and *Coenagrion caerulescens* mainly deposit their eggs into floating dead parts of emergent plants. In their initial choice of oviposition site (selection of landing site) *S. fusca* does not distinguish between fresh and dead plant material, whereas *C. caerulescens* significantly prefers dead material. In *S. fusca*, the missing discrimination of the plant condition in the choice of the landing site is explained by its oviposition period in the beginning of the vegetation period when the green plant material is rare. *C. caerulescens* reproduces in summer and finds dead and living plants side by side. I suggest that in the latter species an early recognition of dead material is advantageous because of the reduction of the expense in searching." (Author)] *S. fusca* was studied between 1989 and 1995 near Gifhorn, Germany, and *C. caerulescens* from 20 to 30 June 1993 at the Canal de Vergières, France.] Address: Martens, A., Zool. Inst. 2152. Mauco, L.; Favero, M.; Bo, M.S. (2001): Food and feeding biology of the Common Tern during the nonbreeding season in Samborombon Bay, Buenos Aires, Argentina. *Waterbirds* 24(1): 89-96. (in English). ["Common Terns (*Sterna hirundo*), which breed in North America and migrate into the southern hemisphere in winter, show a wide nonbreeding distribution that includes the Atlantic coasts of Argentina and Brazil. At Punta Rasa (Samborombon Bay, Argentina), there were about 30,000 Common Terns. Their diet in winter was assessed by the analysis of regurgitated pellets collected at Punta Rasa. Adult Coleoptera, Odonata, Orthoptera and Hemiptera were the main insects found in the diet. A total of 14 species of fishes were identified. Argentine Anchovy (*Engraulis anchoita*) and Anchovy (*Anchoa mitchilli*) (Family Engraulidae), represented 79% by number and the 78% of the consumed biomass of fish prey. The average length of fish prey was 90.0 ± 17.6 mm. Half the prey lived in seawater, while the other half was taken in estuarine or seawater. There was no evidence of fish prey taken by terns foraging in freshwater habitats. Total consumption of food was estimated as 106 tons of fish (most of them juvenile) during a five month period at Punta Rasa." 2154. McPeck, M.A.; Grace, M.; Richardson, J.M. L. (2001): Physiological and behavioral responses to predators shape the growth/predation risk trade-off in damselflies. *Ecology* 82(6): 1535-1545. (in English). ["Most organisms must simultaneously find enough food for themselves while trying not to become food for some other organism. Previous field experiments have shown that larvae of *Enallagma* and *Ischnura* species are able to coexist in the littoral zones of lakes because they resolve this growth/predation risk trade-off differently: *Ischnura* species grow more quickly than *Enallagma* species, but *Ischnura* species suffer higher mortality rates than *Enallagma*. We performed a series of laboratory studies to explore the mechanistic basis for the difference in growth between the genera. When held in complete isolation and with unlimited food, larvae of a number of *Enallagma* species that coexist with fish accumulated mass at much faster rates than *Ischnura* species. This difference in isolation was due to the fish-lake *Enallagma* simply ingesting more food. In contrast,

contrast, when held in the presence of other damselflies or a fish predator, *Ischnura* had significantly higher growth rates than *Enallagma* species from fish lakes. All species decreased the amount of food they ingested in the presence of the fish predator as compared to when fish were absent, which resulted in decreased growth in the presence of the predator for all species. However, the interspecific differences in growth rate were due primarily to differences in the abilities of the species to convert ingested food into their own biomass; in the presence of fish, comparably sized larvae ingested nearly identical amounts of food, but *Ischnura* larvae grew faster because they converted significantly more ingested food into their own biomass than did larvae of *Enallagma* species from fish lakes. This difference in conversion efficiency between the genera was not apparent when larvae were raised in complete isolation. These results indicate that *Enallagma* and *Ischnura* species differ in physiological stress responses to the presence of predators, and this difference may facilitate the coexistence of *Enallagma* and *Ischnura* species in the field." 2157. Misof, B.; Rickert, A. M.; Buckley, T.R.; Fleck, G.; Sauer, K. P. (2001): Phylogenetic signal and its decay in mitochondrial SSU and LSU rRNA gene fragments of Anisoptera. *Molecular Biology & Evolution* 18(1): 27-37. (in English). ["The phylogeny of Anisoptera, dragonflies in the strict sense, has proven to be notoriously difficult to resolve. Based on morphological characters, several recent publications dealing with the phylogeny of dragonflies proposed contradicting inter- and intrafamily relationships. We explored phylogenetic information content of mitochondrial large-subunit (LSU) and small-subunit (SSU) ribosomal gene fragments for these systematic problems. Starting at published universal primers, we developed primer sets suitable for amplifying large parts of the LSU and SSU rRNA genes within dragonflies. These fragments turned out to harbor sufficient phylogenetic information to satisfactorily resolve intrafamily relationships, but they contain insufficient phylogenetic structure to permit reliable conclusions about several interfamily relationships. We demonstrate that decay of phylogenetic signal progresses from intrafamily to interfamily to outgroup relationships and is correlated with an increase of genetic di-

stances. As expected, signal decay is most pronounced in fast-changing sites. Additionally, base composition among fast-changing sites significantly deviates from the expected homogeneity. Homogeneity of base composition among all included taxa was restored only after removing fast-changing sites from the data set. The molecular data tentatively support interfamily relationships proposed by the most recent publication based on morphological characters of fossil and extant dragonflies." 2159. Moore, N.W. (2001): Changes in the dragonfly communities at the twenty ponds at Woodwalton Fen, Cambridgeshire, United Kingdom, since the study of 1962-1988. *Odonatologica* 30(3): 289-298. (in English). ["The pattern of the number of spp. per pond changed completely between 1988 and 2000. The growth of scrub on the edges of the ponds caused a decline in the number of dragonfly spp. when more than 50% of pond edge was shaded by bushes. When the ponds were completely shaded they lost all their dragonfly spp. The decline in spp. appeared to be caused by shading rather than changes in the aquatic flora caused by shading. When the scrub was not controlled the ponds were inhabited by dragonflies from 26 to at least 39 yr. In ponds where no scrub developed, or where it was controlled, *Coenagrion puella*, *Ischnura elegans*, *Aeshna cyanea*, *Libellula quadrimaculata*, *Sympetrum striolatum* and *Sympetrum sanguineum* were still conti-

ning to inhabit the ponds after 39 yr. *Aeshna grandis*, which had occurred most yr. in the 1962-1988 period, was still present in 2000. *Pyrrhosoma nymphula* and *Brachytron pratense*, which had bred from 1964 to 1972 and 1968 to 1973 respectively, both reappeared after 20 yr. absence. Their return to the ponds appeared to be connected with their increase in adjacent habitats at Woodwalton Fen in the 1989-2000 period. *Anax imperator* and *Libellula fulva*, which had also increased at Woodwalton Fen, were seen for the first time at the ponds during this period. The reason for the recent disappearance of *Lestes sponsa* from the ponds and adjacent habitats is not known. This study yet further emphasises the need to conserve large core populations of dragonflies, and it reiterates the need for really long term monitoring." (Author)] Address: Moore N.W., The Farmhouse, 117 Boxworth End, Swavesey, Cambridge CB4 5RA, United Kingdom

2160. Müller, J.; Schorr, M. (2001): Verzeichnis der Libellen (Odonata) Deutschlands. *Entomofauna Germanica* 5: 9-44. (in German with English summary). [Data on the representation of the German odonate fauna are compiled in a table (checklist). Each species is arranged according to its occurrence and its current status in the 16 Federal States of Germany. The compilation is based on an extensive survey and on a critical discussion of literature data. In some cases annotations on nomenclatorial problems are made. In other cases it is mandatory to evaluate the identification of species, to discuss possible misidentifications or to discuss trends of range extension. This refers to the following species: *C. armatum*, *C. ornatum*, *C. scitulum*, *G. pulchellus*, *G. flavipes*, *O. cecilia*, *B. pratense*, *A. isoceles*, *A. ephippiger*, *C. bidentata*, *L. depressa*, *L. fulva*, *C. erythraea*, *S. fonscolombii*, and *S. meridionale*. A selected but representative bibliography and some introductory remarks on the German odonatological history provide some additional information.] Address: Müller, J., Frankefelde 3, D-39116 Magdeburg, Germany. 2163. Naraoka, H. (2001): Post-copulatory behaviour in the dragonfly *Sympetrum parvulum* Bartenef (Anisoptera: Libellulidae). *Odonatologica* 30(4): 411-422. (in English). ["According to their social status, the males are divided into 2 categories: territory holders (territorial males) and non-territory holders (wandering males). The duration of copulation was longer in wandering (461.5±347.8 s.n = 46) than in territorial pairs (201.3±149.8 s.n = 85). Oviposition modes are 3-fold: viz. (1) single, with non-contact guarding (territorial pairs: 115.1±75.5 s.n = 27; wandering pairs: 133.9±45.5 s.n = 14); (2) tandem oviposition (territorial pairs: 214.6±76.6 s.n = 5; wandering pairs: 141.0±76.2s.n = 7); - and (3) tandem oviposition + non-contact guarding (NCGO) (territorial pairs: 131.6±93.8 s.n = 5; wandering pairs: 157.5±72.8 s.n = 2). The first type was most common in territorial (75%) and in wandering pairs (62.1 %). The second type was in wandering pairs (24.1 %) twice as frequent as in territorial pairs (10.4%). The third mode was infrequent (territorial pairs: 14.6%, wandering pairs: 13.8%). The relationships between male social status and the interference of territorial males on one hand, and the duration of copulation and the oviposition mode on the other, are discussed. The effects of vegetation and air temperature on the oviposition mode are briefly outlined." 2167. Oyediran, I.O.; Heinrichs, E.A. (2001): Arthropod populations and rice yields in direct-seeded and transplanted lowland rice in West Africa. *International Journal of Pest Management* 47(3): 195-200. (in English). ["Two methods for planting rice in irrigated lowland were evaluated during the wet seasons of 1994 and 1995 to determine their effect on rice arthropod numbers, insect-caused rice plant damage and rice grain yield. The six treatments tested were: hand transplanting of seedlings at spacings of 14 cm X 14 cm, 20 cm X 20 cm, and 30 cm X 30 cm; and direct-seeding of rice at 60 kg seeds ha⁻¹, 90 kg seeds ha⁻¹ and 120 kg seeds ha⁻¹. The most abundant arthropods in the study were the diopsid flies, *Diopsis longicornis* Maquart and *D. apicalis* Dalman; the green leafhoppers *Nephotettix* spp.; the white leafhoppers *Cofana unimaculata* (Signoret) and *C. spectra* (Distant); spiders; dragonflies and damselflies; and stem borers. There was no overall difference between transplanting and direct-seeding, or between plant densities, in regard to sweep net counts of *Cofana* spp. and spiders. *Diopsis longicornis* and *D. apicalis* adult numbers were highest in the 20 cm X 20 cm transplanted plots in 1994, but no significant differences occurred in 1995. *Nephotettix* spp. adult numbers were highest in the 120 kg seeds ha⁻¹ direct-seeded plots in 1995 but no significant differences occurred in 1994. The percentage of tillers infested with stem borers was highest in the three transplanted and the 120 kg seed ha⁻¹ direct-seeded treatments in 1994 and the three transplanted treatments in 1995. In 1995, the percentage of whiteheads (empty panicles) caused by stem borer feeding was highest in the direct-seeded treatments, increasing from the low rate of 60 kg seeds ha⁻¹ to the highest rate of 120 kg seeds ha⁻¹. Grain yields were generally similar in the transplanted and direct-seeded plots. Implications of planting methods and plant density as management practices in rice IPM and labour requirements for rice production are discussed." ["[...] Although there is a form with a brighter abdomen, showing some blue along its entire length, this has so far not been reported in Britain." This colour form is discussed in detail and compared with *Aeshna mixta*, *Anax ephippiger*, and males and females of *A. imperator*.] Address: Parr, A.J., 10 Orchard Way, Barrow, Bury St. Edmunds, Suffolk IP29 5BX, UK

- 2169.** Peacor, S.D.; Werner, E.E. (2001): The contribution of trait-mediated indirect effects to the net effects of a predator. *Proceedings of the National Academy of Sciences of the United States of America* 98(7): 3904-3908. (in English). ["Many prey modify traits in response to predation risk and this modification of traits can influence the prey's resource acquisition rate. A predator thus can have a "nonlethal" impact on prey that can lead to indirect effects on other community members. Such indirect interactions are termed trait-mediated indirect interactions because they arise from a predator's influence on prey traits, rather than prey density. Because such nonlethal predator effects are immediate, can influence the entire prey population, and can occur over the entire prey lifetime, we argue that nonlethal predator effects are likely to contribute strongly to the net indirect effects of predators (i.e., nonlethal effects may be comparable in magnitude to those resulting from killing prey). This prediction was supported by an experiment in which the indirect effects of a larval dragonfly (*Anax* sp.) predator on large bullfrog tadpoles (*Rana catesbeiana*), through nonlethal effects on competing small bullfrog tadpoles, were large relative to indirect effects caused by density reduction of the small tadpoles (the lethal effect). Treatments in which lethal and nonlethal effects of *Anax* were manipulated independently indicated that this result was robust for a large range of different combinations of lethal and nonlethal effects. Because many, if not most, prey modify traits in response to predators, our results suggest that the magnitude of interaction coefficients between two species may often be dynamically related to changes in other community members, and that many indirect effects previously attributed to the lethal effects of predators may instead be due to shifts in traits of surviving prey." - 2172.** Phillips, E.C. (2001): Life history, food habits and production of *Progomphus obscurus* Rambur (Odonata: Gomphidae) in Harmon Creek of east Texas. *Texas Journal of Science* 53(1): 19-28. (in English). ["*P. obscurus* is a burrowing dragonfly species which is abundant in eastern Texas sandy streams. The naiads and adults of *P. obscurus* were collected from and around Harmon Creek (Walker County, Texas) from November 1995 through May 1997. This species has a univoltine life cycle and produces a total of 11 instars. At Harmon Creek, emergence of adults began in mid April and continued until mid to late September. Oviposition was observed from early May through mid August. First instar naiads were collected from May through early September. May, June and July were the months of greatest recruitment. Penultimate naiads were first collected during late February. The annual secondary production estimate for *P. obscurus* was 6.842 g/m²/yr, the standing stock biomass was 1.682 g/m², and the cohort production/biomass ratio (P/B ratio) was 4.067. The primary food items consumed by naiads of *P. obscurus* were chironomid larvae, followed by mayfly naiads of the families Caenidae and Baetidae." - 2175.** Reinhardt, K.; Gerighausen, U. (2001): Oviposition site preference and egg parasitism in *Sympecma paedisca* (Odonata: Lestidae). *Int. Jour. Odonatology* 4(2): 221-230. (in English). ["Oviposition of *Sympecma paedisca* was observed in eastern Kazakstan. The main oviposition substrates were living *Phragmites* leaves. In comparison with European and Japanese popu-

lations we propose geographic variation in the proportional use of horizontal versus vertical oviposition substrates. Ovipositing females seemed to avoid the inner parts of Phragmites stands and there was a preference for individual plants. Eggs were on average 1.28 mm long and densities of up to one egg per mm² leaf area were observed. Parasitoid wasps of the genus *Anagrus* emerged from almost 2% of 13,938 eggs examined. Further estimates revealed that 22.4% of the eggs were parasitized. There was no significant correlation between the degree of parasitism and egg density. We propose that clutch size may not be the best female fitness parameter in endophytically laying odonate species." 2176. Relyea, R.A. (2001): The lasting effects of adaptive plasticity: Predator-induced tadpoles become long-legged frogs. *Ecology* 82(7): 1947-1955. (in English). ["Changes in environmental conditions often alter the traits of individuals; however, we have a poor understanding of how changes in phenotypically plastic traits early in development may affect traits later in life. Such effects are of particular interest in organisms with complex life cycles in which early and late life stages can have drastically different morphologies and occupy different habitats. In this study, I examined how differences in the mass, morphology, and larval period of wood frog tadpoles (*Rana sylvatica*) subsequently affected the mass and morphology of metamorphic frogs. I found three major patterns: (1) larval mass and larval period were positively related to metamorphic mass; (2) larval period was positively related to metamorph hindlimb and forelimb length and negatively related to metamorph body width; and (3) larval body length was positively related to metamorph forelimb size. I then used these correlations to interpret the connection between the traits of predator-induced tadpoles and the subsequent traits of metamorphic frogs. Tadpoles reared with caged predators (aeshnid dragonflies) developed relatively deeper tail fins and had shorter bodies, lower mass, and longer developmental times than tadpoles reared without predators. Metamorphs emerging from larval predator environments exhibited no differences in mass but developed relatively large hindlimbs and forelimbs and narrower bodies than metamorphs emerging from predator-free larval environments. These differences arose primarily due to predator-induced changes in larval development time and not due to the predator-induced changes in larval morphology. By focusing on a large number of traits and a wide range of trait values, one can readily generate predictions about how a variety of environments, which alter traits early in development, can subsequently alter traits later in development." 2177. Richardson, J. (2001): A comparative study of activity levels in larval anurans and response to the presence of different predators. *Behavioral Ecology* 12(1): 51-58. (in English). ["Activity level is a key behavioral trait in many animals which mediates a trade-off between finding food and avoiding predation. Optimal activity level will therefore depend on environment, and plasticity in response may increase fitness (if an organism encounters multiple environments in a lifetime).

One group in which activity level, and its relationship to foraging and predation risk, has been well studied is larval anurans. Anurans inhabit a range of distinct freshwater aquatic community types that are created by differences in pond permanency and top predator. Species segregate across these pond types and therefore tadpoles from different species encounter different selection regimes. I hypothesized that species from different pond types would therefore differ in activity behavior, and in plasticity of this behavior. I tested this in a phylogenetic framework to consider the evolution of plasticity in anurans diversifying into different pond types. Time spent active was quantified for larvae of each of 13 anuran species (from three taxonomic families) in four conditions: when no predator was present, and in the non-lethal presence of a dragonfly, newt, or fish predator. Species nested within pond type by taxonomic family differed significantly in time spent active. A significant interaction between predator treatment and taxonomic family was also observed. A phylogenetic analysis of change in behavior revealed strong positive correlations in evolution of these behaviors and suggests constraints on the ability of larval anurans to independently modify activity levels in the presence versus absence of predators." 2180. Ryazanova, G.I. (2001): Ontogenesis of behavior in insects: Specific features in sexual behavior of odonate larvae. *Zoologicheskii Zhurnal* 80(1): 45-51. (in Russian with English summary). ["Specific features in sexual behavior of *Calopteryx splendens* Harris larvae were revealed. Such a specificity was found in responses of larvae to a large threatening object and in conspecific interactions of larvae. The behavioral peculiarities are manifested to a greater degree in increasing the aggressiveness of male larvae resulted in a greater damage of them. The specific sexual behavior described is considered as a display of forming the future imago behavior similar to developing imaginal morphology in larvae of hemimetabolic insects. The behavior of elder larvae is characterized as a forced compromise of the larva adaptive behavior and peculiarities of developing imaginal behavior which are of no adaptive value." 2181. Sahlén, G.; Ekestubbe, K. (2001): Identification of dragonflies (Odonata) as indicators of general species richness in boreal forest lakes. *Biodiversity & Conservation* 10(5): 673-690. (in English). ["We argue the need to select indicator species on empirical data to avoid influence of personal opinions. To test an empirical selection process based on a nested subset matrix, we sampled partivoltine dragonfly larvae from 74 small lakes in central Sweden. A nestedness matrix was set up using the 'nestedness temperature calculator' program, selecting 11 species as potential indicators of species richness. These were tested against a known indicator species for water quality (the pool frog) and plant diversity through inventories and comparison to existing surveys of biological values ('rich' lakes vs. 'ordinary' lakes). We could only see a trend towards the pool frog occurring in dragonfly-rich lakes, but found a significant connection between the number of aquatic plants along the shore line and the number of dragonfly species present. A significantly higher number of indicators were encountered in lakes previously surveyed as 'rich' in plants than in lakes classified as 'ordinary'. Dragonfly species richness therefore appears to be positively associated with species richness of vascular plants. We propose nestedness matrices to be a good selecting tool for indicator species, particularly in groups where the biology of the species is not well known. However, it is important to define what such indicators really indicate." 2186. Sherwin, G. (2001): White-faced Darter *Leucorrhinia dubia* and Black Darter *Sympetrum danae* in Tandem. *Atropos* 14: 64. (in English). [United Kingdom, Scotland, Highlands, Glen Affric, 27 July 2001; mixed couple of a *Sympetrum danae* male and a female of *Leucorrhinia dubia* with a blue coloured abdomen] Address: Sherwin, G., The Beeches, Sporle Road, Little Dunham, Kings Lynn, Norfolk, PE32 2DG, UK

2187. Silsby, J. (2001): Dragonflies of the world. Natural History Museum, London. ISBN 0-565-09165-4: VII + 216 pp. (in English). [This valuable book presents, for the first time, a comprehensive account of representatives of each of the 73 subfamilies of the Odonata, together with an account of their habits and habitats, and clear colour photographs of preserved or (more often) living specimens of larvae and adults and (sometimes) typical habitats. In this regard it fills a long-standing lacuna in the odonatological literature. Besides the main chapter devoted to representatives of subfamilies, there are 12 others treating various aspects of odonate biology, five of which have been authored by appropriate specialists. Eight other specialists have contributed sections within chapters. A wide range of diverse information about odonate biology is included in the book, for the most part being cited to secondary sources. Apart from its unique value in documenting representatives of all subfamilies, the book is likely to be much in demand for its many beautiful photographs, of odonates and of their habitats, mostly by the author, but including those from 27 other people. Another strength of the book, which achieves a stated aim of the author, is that biological and technical information is presented in a way that makes it readily accessible, and enjoyable, to the non-specialist. The book has been attractively produced, and the lay-out makes excellent use of the large page size of 22.5 x 25.5 cm. It is expected that all odonatologists, no matter how experienced they are, will wish to possess a copy of this fine book. Philip Corbet] Address: The Natural History Museum, Cromwell Road London SW7 5BD, UK. Price: £27.50

2188. Sirot, L.K.; Brockmann, H.J. (2001): Costs of sexual interactions to females in Rambur's fork-tail damselfly, *Ischnura ramburi* (Zygoptera: Coenagrionidae). *Animal Behaviour* 61(2): 415-424. (in English). ["Several species of damselflies, dragonflies and butterflies are characterized by a female-limited polymorphism in which one type of female, the andromorph, looks and behaves like males whereas the other type of female, the gynomorph, looks and behaves differently. Sexual conflict has been hypothesized to play a role in the maintenance of this polymorphism in that andromorphs

may have an advantage over gynomorphs by avoiding costly sexual interactions through male mimicry. We tested for costs of sexual interactions to female *Ischnura ramburi* damselflies by comparing the success of singly mated females maintained with no males to the success of females maintained continuously with males at a 3:1 (male to female) operational sex ratio (OSR) and a 1:1 OSR. Our findings suggest that sexual interactions affect the two morphs differently. The time spent feeding, number of eggs laid and egg-laying rate of andromorphs were lower in the 3:1 OSR treatment than in the treatment with no males. Time spent feeding and number and rate of eggs laid by gynomorphs did not differ among treatments. Sexual conflict may be occurring between males and mated andromorphs because sexual interactions are associated with net costs to mated andromorphs whereas sexual interactions with mated andromorphs are beneficial to males because there is high last-male sperm precedence. Based on this experiment, andromorphs cannot be said to have an advantage over gynomorphs by avoiding costly sexual interactions because sexual interactions were not associated with net costs to gynomorphs." 2189. Siva-Jothy, M.T.; Tsubaki, Y.; Hooper, R.E.; Plaistow, S.J. (2001): Investment in immune function under chronic and acute immune challenge in an insect. *Physiological Entomology* 26(1): 1-5. (in English). ["In this paper we investigate the relationship between the chronic burden of mid-gut parasites (eugregarine trophozoites) and the effect of an acute haemolymph challenge (a nylon insert) on two important insect immune effector systems (phenol oxidase (PO) and the encapsulation response) in a field-population of damselflies. PO levels in the haemolymph, and the magnitude of the encapsulation response were maintained, regardless of chronic and subsequent acute experimental immune challenges. The maintenance of these effector systems is therefore probably an important life-history requirement in these damselflies. Investment in mid-gut PO levels was significantly negatively related to the animal's chronic parasite burden after an acute experimental challenge in the haemolymph, suggesting that maintaining PO levels across two physiological compartments (haemolymph and mid-gut) is costly. The results suggest that the immune effector system activity in different physiological compartments in an insect's body is affected by chronic parasite burdens in the face of the demands imposed by an acute immune insult." 2192. Stoks, R. (2001): Male-biased sex ratios in mature damselfly populations: Real or artefact? *Ecological Entomology* 26(2): 181-187. (in English). ["1. There is ongoing controversy about whether biased sex ratios in diploid insect populations are real or an artefact caused by different behaviours and/or different catchability of the sexes. This was tested by monitoring two field and three semi-natural populations of the damselfly *Lestes sponsa*. 2. Capture-mark-recapture data showed that population size estimates were about twice as large for males as for females at both field sites. Independent estimates of the sex ratios based on total numbers of males and females captured supported the male bias. 3. Males had higher recapture probabilities than females due to longer times between successive visits in females. Because the same pattern was found in the semi-natural populations, the longer intervals in females are no artefact due to their lower detectability. 4. Theoretical models show that the strong temporary emigration of females tends, if anything, to overestimate female population sizes and that the heterogeneity of recapture probabilities observed in males tends to underestimate male population sizes. Hence, behavioural differences between the sexes do not cause an artificially male-biased sex ratio. 5. Spatial data show that operational sex ratios are male biased at the pond but become female biased in the plots further away from the shoreline; however because of the decrease in densities away from the shoreline, this does not result in a global even sex ratio. 6. Spatial data, temporary emigration patterns, and independent estimates suggest strongly that the male-biased sex ratios in mature damselfly populations are real." 2193. Stoks, R. (2001): What causes male-biased sex ratios in mature damselfly populations? *Ecological Entomology* 26: 188-197. (in English). ["1. Several hypotheses to account for biased sex ratios in mature insect populations were tested by monitoring two field popula-

tions of the damselfly *Lestes sponsa* and by performing experiments in field cages. The population sex ratios are heavily male biased in this species. 2. The observed sex ratio at emergence was even and both sexes emerged synchronously. Females had longer maturation times but these were insufficient to explain the observed sex ratio shift. 3. Mass increases during maturation were consistently larger in females. In agreement with this, immature females made more flights per unit of time, which should make them more vulnerable to predation, however maturation probabilities were lower in females only in one field cage experiment. This inconsistency may be due to long bad weather conditions. Interestingly, predators reduced mass increase and this reduction was larger in females than in males. 4. Calculations based on the sex specific maturation times show that only slightly lower daily survival probabilities during maturation in females are enough to generate the observed sex ratio shift. 5. Mature survival was higher in males than in females in one field population but not in another, indicating that this cannot be a general mechanism causing the sex ratio. A higher maturation probability in males is therefore the most plausible mechanism causing the sex ratio shift in damselfly populations." (Author)] Address: Stoks, R., Laboratorium voor Aquatische Ecologie, K.U.Leuven, De Beriotstraat 32, B-3000 Leuven, Belgium. E-mail: robby.stoks@bio.kuleuven.ac.be

2194. Suh, A.; N.; Samways, M.J. (2001): Development of a dragonfly awareness trail in an African botanical garden. *Biological Conservation* 100: 345-353. (in English). ["The IUCN/SSC Status Survey and Conservation Action Plan: Dragonflies calls for an increase in educating the public and increasing awareness of dragonflies (Odonata). Dragonflies are conspicuous and attractive, and can 'stand in' for other invertebrates in raising awareness of the necessity to conserve invertebrates. While reserves have been set aside for dragonfly awareness and conservation in the northern hemisphere, no such dragonfly reserves appear to exist in the southern hemisphere, despite its rich dragonfly fauna. This paper describes the development of a dragonfly-awareness trail in an established and well-visited botanical garden (The National Botanical Gardens, Pietermaritzburg, South Africa). Correlations between species and environmental variables were significantly high for six measured environmental variables: pH, percentage shade, vegetation (structural and compositional), ambient and water temperature, and water depth. Multivariate analyses of data, classified 20 a priori selected sampling units into four ecologically meaningful biotope types, each with a characteristic dragonfly assemblage. The four biotopes provided potential viewing points. To these were added a further three duplicate biotopes so as to link the trail into a circuit. Questionnaires assessed public awareness of dragonflies, and helped design a preliminary leaflet. A final trail design was drawn up along with an expanded booklet. The trail has now been implemented. Recommendations are made on the minimal scientific underpinning required for future trail design." 2195. Suhling, F.; Lepkojus, S. (2001): Differences in growth and behaviour influence asymmetric predation among early-instar dragonfly larvae. *Canadian Journal*

of Zoology 79(5): 854-860. (in English with French summary). ["Libellulid dragonflies lay large egg clutches. When eggs of two or more species are deposited at the same time and patch, one can expect a high density of early-instar larvae. Thus, interspecific interactions should be evident. We studied the interaction of two species, *Sympetrum fonscolombii* and *Orthetrum cancellatum*, which typically co-occur in French rice fields. We experimentally simulated the laying of egg clutches of both species at the same time and site. Survival of *O. cancellatum* was reduced compared with that of controls without *S. fonscolombii* and also with that of *S. fonscolombii* in the two-species treatment. At the end of the experiment, mean head width of *S. fonscolombii* was greater than that of *O. cancellatum*, which may be one reason for the differential survival. In a second experiment we observed the behaviour of pairs of early-instar larvae of both species in different size combinations. Small larvae of *S. fonscolombii* reduced locomotory activity in the presence of larger *O. cancellatum*. In contrast, small *O. cancellatum* did not do so in the presence of larger *S. fonscolombii*. This behavioural difference may also cause asymmetric interspecific predation." (Authors)] Address: Suhling F., Zool. Inst., TU Braunschweig, Fasanenstr. 3, D-38092 Braunschweig, Germany. E-mail: f.suhling@tu-bs.de

2196. Suhling, F. (2001): Intraguild predation, activity patterns, growth and longitudinal distribution in running water odonate larvae. *Archiv für Hydrobiologie* 151(1): 1-15. (in English). ["I studied predation by larval *Cordulegaster boltonii* on larvae of two other dragonfly species in a laboratory artificial stream. *Onychogomphus forcipatus unguiculatus* suffered significantly higher predation than *Onychogomphus uncatus*. Activity was much lower in *O. uncatus*, which is interpreted as an antipredation trait against *C. boltonii*. The higher activity of *O. f. unguiculatus* makes it vulnerable to the Sit-and-wait predator *C. boltonii* due to increased encounters. Rearing of both *Onychogomphus* in field cages under the same conditions of temperature, food availability and density revealed lower growth rates of *O. uncatus*, which may be interpreted as a cost of the antipredation behaviour. To test whether experimental results have relevance for large-scale distribution patterns of the two *Onychogomphus*, samples were taken at 23 sites in river-systems of southern France where both species co-occur. In the field I found that *O. f. unguiculatus* does not coexist with *C. boltonii* at sites where the latter occurs in high numbers. In contrast, *O. uncatus* is established even at high density of *C. boltonii*." (Author)] Address: Suhling F., Zool. Inst., TU Braunschweig, Fasanenstr. 3, D-38092 Braunschweig, Germany. 2200. Thurnheer, S.; Reyer, H.-U. (2001): Spatial distribution and survival rate of waterfrog tadpoles in relation to biotic and abiotic factors: A field experiment. *Amphibia-Reptilia* 22(1): 21-32. (in English). ["Predictions about population and community dynamics are usually based on lab experiments. Because the results are difficult to transfer to natural conditions, the major purpose of this study was to test the effects of biotic and abiotic factors on tadpole populations in a natural environment. We stocked six ponds, created the previous year, with known numbers of *Rana esculenta* and *R. lessonae* tadpoles and followed their development over several months. When compared among ponds, tadpole density correlated positively with the nitrate:phosphate ratio. This suggests that water chemistry may have affected survival, either directly or indirectly via productivity. Within ponds, both species showed a clear preference for the shallow zone. This behavior probably reflects a preference for warm water close to the surface, rather than avoidance of predators, because relative densities of odonates also increased from deep to shallow zones. This study is one of few that not only considers the distribution of the anuran tadpoles but the distribution of their predators as well." (Authors)] Address: Thurnheer, Sylvie, Zoological Institute, University of Zürich, CH-8057 Zürich, Switzerland. E-mail: ulireyer@zool.unizh.ch

2201. Tolonen, K.T.; Hämäläinen, H.; Holopainen, I. J.; Karjalainen, J. (2001): Influences of habitat type and environmental variables on littoral macroinvertebrate communities in a large lake system. *Arch. Hydrobiol.* 152(1): 39-67. (in English). ["The community structure of littoral macroinvertebrates was explored by multivariate analyses in three basins of the large Lake Saimaa system (eastern Finland). The basins differed in trophic status and degree of human influence. It was hypothesized that the structure of littoral invertebrate communi-

ties is influenced by lake trophic status, as is the case in profundal communities. Three littoral habitat types with different substrate (stony, sandy and vegetated shores) were sampled from the shoreline to a depth of 1.5-3 meters. The habitat type was found to be largely determined by the slope of the shore and the wind exposure. Each habitat type supported fairly characteristic fauna, and detrended correspondence analysis grouped the invertebrate assemblages by habitat type rather than by basin. Within each habitat type, canonical correspondence analysis indicated that species composition changed along the trophic gradient. In the vegetated littoral zone, the greatest change in community structure occurred within the macrophyte beds, varying from the outer edge of macrophytes to the shoreline. Two alternative or complementary explanations are given for this horizontal gradient. First, a horizontal gradient of abiotic characteristics results in a change of community composition. Second, the macrophyte beds may form a horizontal transition zone in predation, from invertebrate predation inshore to fish predators offshore. On the stony and sandy shores, the magnitude of wave action was also important in structuring the communities. As each habitat type harbors characteristic fauna, a variety of habitats needs to be protected in order to conserve littoral macroinvertebrate diversity in large lakes. To make among-lake comparisons of littoral macroinvertebrate assemblages, stratification by habitat type is obviously necessary. The effects of eutrophication on invertebrate assemblages were most pronounced in stony habitats." (Authors) 13 odonate taxa (11 on species level) are listed in appendix 1.] Address: Tolonen, K.T., Department of Ecology, Karelian Institute, University of Joensuu, P.O. Box 111, 80101 Joensuu, Finland. E-mail: ktolonen@cc.joensuu.fi

2204. Weekers, P.H.; De Jonckheere, J.F.; Dumont, H.J. (2001): Phylogenetic relationships inferred from ribosomal ITS sequences and biogeographic patterns in representatives of the genus *Calopteryx* (Insecta: Odonata) of the West Mediterranean and adjacent West European zone. *Molecular Phylogenetics & Evolution* 20 (1): 89-99. (in English). ["Western Europe is a reinvansion zone for the riverine dragonfly genus *Calopteryx* (Insecta: Odonata). Reinvansion may have been from central West Asia or from the West Mediterranean refugium. Phylogenetic relationships of West Mediterranean and West European taxa of the genus *Calopteryx* from different localities were inferred from sequences of the internal transcribed spacers (ITS1 and ITS2) of the nuclear

ribosomal RNA genes. 26 taxa belonging to the species groups *C. splendens*, *C. meridionalis*, *C. haemorrhoidalis*, *C. virgo*, *C. xanthostoma*, and *C. exul* were analyzed, with two North American species, *C. amata* and *C. aequabilis*, as outgroup. Sequence data and phylogenetic analyses were used to infer biogeographical patterns. The ribosomal spacers (ITS1 and ITS2) and the intervening 5.8S rDNA gene were amplified by PCR and sequenced. The ITS2 sequences of the West Mediterranean and West European calopterygids show no length variation but the ITS1 region was slightly variable in length. The sequence variation for ITS1 and ITS2 regions between different West Mediterranean and West European calopterygids was 14.5 and 6.1%, respectively. Phylogenetic relationships inferred from ITS sequences only partly confirm morphological data. A monophyletic origin of all West Mediterranean and West European species emerged. They are separated into two main clades; the splendens-like forms and the virgo/meridionalis/haemorrhoidalis group. Intraspecific variability, indicating different stages of speciation, was detected only in West Mediterranean representatives (e.g., *C. xanthostoma*) but not in invasive representatives in West Europe. The North African endemic *C. exul* is more closely related to the Italian *C. s. caprai* than to *C. splendens sensu strictu*. Based on the present information, Cretan populations are the only splendens-like taxa in addition to *C. s. caprai* that deserve subspecies status." (Authors)] Address: Dumont, H.J., Univ. Gent, Inst. Animal Ecology, K.L. Ledeganckstr. 35, B-9000 Gent, Belgium. E-mail: Henri.Dumont@rug.ac.be

2205. Wendzonka, J. (2001): Dragonflies (Odonata) of Gostyn at its environs (southern Wielkopolska). *Badania fizjograficzne nad Polska zachodnia Ser. C., Zool.* 48: 29-39. (in Polish with English summary). [In 1995-2000 the Odonata of Gostyn and its environs in southern Wielkopolska-Kuiawy Lowland, Poland have been investigated. A total of 44 species was recorded, including several rare species such as *Aeshna affinis*, *Orthetrum albistylum*, *Sympetrum striolatum*, *Leucorrhinia caudalis*, and *L. albifrons*, and some species which are not rare but "insufficiently presented in published papers", such as *Lestes barbarus*, *Ischnura pumilio*, and *Erythromma viridulum*. *A. affinis* has its northern range limit in Wielkopolska ("Great Poland"), so this is a region where the species reproduces probably only temporarily. *O. albistylum*, almost till the end of the 20th century only known from the south of Poland, now has been found also in other parts of the country, mostly in mid-eastern and northeastern parts. Two localities near Gostyn, described in this paper, are the northernmost in western Poland. *O. albistylum* significantly prefers gravel and sand pits, unshaded habitats, protected from wind, generally with well-developed vegetation but also with some bare patches. At the locality Pokrzywnica *O. albistylum* predominated over the rare *O. cancellatum*, however in Smilowo the former species was rare and occupied positions away from water. In Smitowc only tandems and ovipositing females used habitats, where *O. cancellatum* and *L. depressa* (aggressive towards each other) predominated.] Address: Wendzonka, J., Zakład Ekologii, Akademia Bydgoska im. 2208. Wildermuth, H. (2001): Das Rotationsmodell zur Pflege kleiner Moorgewässer. - Simulation naturgemäßer Dynamik. *Naturschutz und Landschaftsplanung* 33(9): 269-273. (in German with English summary). ["The model describes a management mode enabling the establishment of a mosaic of all succession stages, with changes in space and time on a confined area. By offering different succession stages at the same time it is intended to provide permanent habitats for a high diversity of aquatic organisms. The model simulates the fictitious dynamics of small water bodies in certain moorland biotopes formerly unimpaired by human activities. It has been applied for about 20 years in a nature reserve in the Swiss Alpine Foothills where peat was exploited by hand up to 1950. Long-term monitoring of selected plant and animal taxa shows that typical biocoenoses of small peat ponds could be preserved and promoted in various succession stages. Special attention was given to the population dynamics of the local dragonfly fauna including the highly endangered *Leucorrhinia pectoralis*, a species of the Bern Convention and the Habitats Directive of the EU. The prerequisites, possibilities and limits of the model are discussed with respect to biodiversity conservation and landscape management as well as in terms of their practicability."] (Author)] Address: Wildermuth, H., Haltbergstr. 43, CH-

8630 Rütli, Switzerland. E-mail: hansruedi@wildermuth.ch

2209. Wong, A.; Forbes, M.R.; Smith, B.P. (2001): Characterization of AFLP markers in damselflies: Prevalence of codominant markers and implications for population genetic applications. *Genome* 44(4): 677-684. (in English with French summary). ["Amplified fragment length polymorphism (AFLP) analysis is becoming increasingly popular as a method for generating molecular markers for population genetic applications. For practical considerations, it is generally assumed in population studies that AFLPs segregate as dominant markers, i.e., that present and absent are the only possible states of a given locus. We tested the assumption of dominance in natural populations of the damselfly *Nehalennia irene* [...] Electro-blotted AFLP products from 21 samples were probed with individual markers. Eleven markers were analyzed, of which two were monomorphic and nine were polymorphic. Only two of the polymorphic markers behaved in a strictly dominant manner. The remaining seven polymorphic markers displayed various degrees of codominance, with 2-10 visible alleles in the sample. Of the three markers displaying the highest degree of variability, two contained microsatellite repeat tracts. Our results suggest that the assumption of dominance is unfounded. As a result, AFLP analysis may be unsuitable for estimating several important population genetic parameters, including genetic diversity."] (Authors)] Address: Forbes, M.R., Dept of Biology, Carleton University, 587 Tory Building, 1125 Colonel By Drive, Ottawa, ON K1S 5B6, Canada. 2210. Wood, P.J.; Greenwooda, M.T.; Barkerb, S.A.; Gunn, J. (2001): The effects of amenity management for angling on the conservation value of aquatic invertebrate communities in old industrial ponds. *Biological Conservation* 102: 17-29. (in English). ["The conservation value of aquatic macroinvertebrate assemblages in old industrial mill ponds was examined within the urban environment. Of the 60 pond sites identified, 18 (31%) have been drained and/or redeveloped since 1985. Canonical correspondence analysis identified differences between the invertebrate communities of managed and unmanaged ponds. Community composition was strongly influenced by the percentage of vegetation cover and the presence of stocked fish for recreational angling. Managed/ stocked ponds have communities dominated by burrowing Oligochaeta and Chironomidae. Unmanaged sites had higher macroinvertebrate diversity compared to managed/stocked ponds and were typified by larval Trichoptera, Coleoptera and Zygoptera. However, unmanaged and 'derelict' sites are at greater risk of drainage and redevelopment in the urban environment. The potential conflict between active management of old industrial mill ponds for recreational angling and the conservation of macroinvertebrate biodiversity is explored."] (Authors) In an appendix the invertebrate taxa recorded and the number of ponds at which they were recorded are documented: *Coenagrion puella* (15), *Ischnura elegans* (14), *Enallagma cyathigerum* (12), and *Pyrrhosoma nymphula* (1).] Address: Wood, P.J.; Department of Geography, Loughborough University, Loughborough, Leicestershire, LE1 1 3TV, UK. 2211. Woodward, G.; Hildrew, A.G. (2001): Invasion of a stream food web by a new top predator. *Journal of*

Animal Ecology 70(2): 273-288. (in English). [1. A new top predator, the dragonfly *Cordulegaster boltonii* Donovan, 'invaded' a stream with a well-described food web. 2. The pre-invasion web was species-poor but complex, with prevalent intraguild predation, cannibalism and omnivory. Such characteristics differ from expectations based upon the early food web literature, but are consistent with more recent empirical webs and theoretical developments. 3. Exhaustive sampling was necessary to describe web structure, with the gut contents of several hundred individuals being required to reach the asymptote of the total number of links for individual species. There was no single 'standard' sample size that was applicable for estimating the number of links: sampling 'x' guts gave a different fraction of the asymptotic value for different species. Smaller predators were more prone to under-estimation of links than larger species higher in the web. 4. The number of feeding links, trophic status and the degree of omnivory increased progressively with predator body size, both within and among species. The diet of each predator species (or instar) was effectively a subset of the diet of the next largest predator. 5. The invader was extremely polyphagous and fed at all trophic levels. Mean chain length increased by half a link following the invasion. Web complexity, and omnivory in particular, also increased. Pre- and post-invasion webs displayed intervality and rigid circuitry. The resident predators were frequently eaten by the invader, but the only significant predators of *C. boltonii* were larger conspecifics. Although no species have yet been deleted, there has been a 21% increase in links for a 6% increase in species since the invasion, suggesting that the members of the web had become more tightly packed within niche space. Most prey species were eaten by every predator species (including *C. boltonii*), indicating the potential for strong apparent competition within the web." (Authors)] Address: Woodward, G., IERM, University of Edinburgh, Mayfield Road, Edinburgh, EH9 3JU: UK. E-mail: Guy.Woodward@ed.ac.uk

2212. Worthen, W.B.; Blue, T.; Haney, D.C.; Andersen, C.B. (2001): Abundance of *Boyeria vinosa* larvae in the Enoree River basin, USA: chemical, physical, and biological correlates (Odonata: Aeshnidae). *Int. Jour. Odonatology* 4(2): 231-240. (in English). [Relationships between the abundance of *B. vinosa* larvae and the chemical, physical and biological properties of the Enoree River of South Carolina, USA and nine of its tributary stream systems are described. "The abundance (number/sample) of *B. vinosa* was positively correlated with stream means for pH, bicarbonate, silicon, magnesium, and calcium ($p < 0.01$). Also, *B. vinosa* were more abundant in streams with a higher frequency of sandy bottoms sites ($r = 0.622$, $p < 0.05$). At the site scale, sites with *B. vinosa* had significantly more crayfish, fish, and other odonates, higher pH, and dissolved oxygen, and less chloride than sites without *B. vinosa* (Mann-Whitney U tests, $p < 0.05$). Where *B. vinosa* were present, abundance was positively correlated with fish abundance, odonate abundance, pH, conductivity, and concentrations of sodium, calcium, magnesium, bicarbonate, bromine, silicon, and aluminum ($p < 0.05$). As such, larval abundance of *B. vinosa* was strongly correlated with chemical and physical parameters at both site and stream scales, but only covaried with the abundance of other organisms at the site scale. Larval abundance did not correlate with the abundance of predatory centrarchid fish at either scale." (Authors)] Ad-

dress: Worthen, W.B. D., Department of Biology, Furman University, Greenville, SC, USA, 29613. E-mail: worthen@furman.edu

2213. Wright, A.B.; Smock, L.A. (2001): Macroinvertebrate community structure and production in a low-gradient stream in an undisturbed watershed. *Arch. Hydrobiol.* 152(2): 297-313. (in English). ["Macroinvertebrate community composition, abundance and production were measured in a sand-bottomed, headwater stream on the Coastal Plain physiographic province in the southeastern U.S.A. The stream's watershed had experienced almost no anthropogenic disturbance for over 100 years and thus the stream represented as close to pristine, reference conditions as occurs in this geographic region. Macroinvertebrates were sampled over one year in the three dominant habitats in the stream: sand sediment, submerged wood and macrophytes (*Sparganium americanum*). Total taxa richness as well as the taxa richness of Ephemeroptera, Plecoptera, Trichoptera and Chironomidae all were greater than in streams flowing through more disturbed watersheds in the area. Annual mean habitat-specific density and biomass were highest in the sediment; density was lowest on the wood and biomass lowest on *Sparganium*. Habitat-specific production was $39-42 \text{ gm}^{-2} \text{ y}^{-1}$ in the sediment and on wood and $16 \text{ gm}^{-2} \text{ y}^{-1}$ on *Sparganium*. The majority of production in all three habitats was by Chironomidae, which comprised 80-92% of total production in each habitat. Taxa in the collector-gatherer and predator functional feeding groups accounted for the majority of production in the sediment and on wood, whereas filter-feeders were predominant on *Sparganium*. Whole-stream production, calculated by summing habitat-specific values that had been weighted for habitat availability, was $64 \text{ gm}^{-2} \text{ y}^{-1}$, considerably higher than production in more disturbed streams in the region. About 65 % of the total production occurred in the sediment, 26 % on wood, and 9 % on *Sparganium*. [...] The production to biomass ratio for the macroinvertebrate community was 33.3; ratios for six taxa of chironomids exceeded 100. Along with the higher species richness in this stream, production of macroinvertebrates was at least twice as high as that in nearby streams with more disturbed watersheds. These differences may be attributable to the long time since the last anthropogenic disturbance of the stream's watershed, which has led to a mature forest covering nearly all of the watershed and which has resulted in a more stable stream flow and less disturbance of the sediment during high flow than in streams in more disturbed watersheds." (Authors) In tab. 1 *Boyeria vinosa*, *Calopteryx maculata*, *Cordulegaster maculata*, and *Dromogomphus spinosus* are listed.] Address: Smock, L.A., Department of Biology, Virginia Commonwealth University, Richmond, Virginia, U.S.A. 23284-2012.

2214. Yourth, C.P.; Forbes, M.R.; Smith, B.P. (2001): On understanding variation in immune expression of the damselflies *Lestes* spp. *Canadian Jour. Zoology* 79(5): 815-821. (in English with French summary). ["Immune ability and immune expression have been viewed as life-history traits that are influenced by such factors as the likelihood of being parasitized, intensity and costs of parasitism, and trade-offs associated with immune expression. In this paper we show that different patterns of infestation by a generalist ectoparasite, *Arrenurus planus* Marshall (Arrenuridae: Hydrachnida), do not fully explain the variation in immune expression ac-

ross four species of sympatric damselflies (Lestidae: Zygoptera). Within species, no gender biases in immune expression were evident. Whereas both males and females of one oft-exploited species did not mount immune responses against attending larval mites, males and females of three other species showed similar immune responses, with variable expression. The immune response was melanotic encapsulation of mite feeding tubes, and was associated with dead mites. Of the three species showing immune expression, the species with the highest prevalence and intensity of infestation had a significantly higher proportion of individuals responding immunologically to mites. In conclusion, current infestation levels only partially predict immune investment; consideration of the timing of emergence of different species suggests that season may be an important predictor of immune investment." - 2220.** Nishu, S. (1997): Report of the survey trip of the Hyogo Society of Odonatology, Part 1 in 1996. *Sympetrum Hyogo* 4: 8-13. (in Japanese with English summary). [27 species have been recorded on April 28 and May 6, 1996. Special emphasis was given to *Libellula angelina*. This endangered species was found in low abundance at Sara Pond, Fukuden-cho, Ono City, but none was observed in the additionally visited habitat Maruodani, Kobe City. "The latter pond lost its water because of drought in 1994, leak from cracks of pond walls caused by the great earthquake in 1995 and complete drainage for the repairing works in 1995 and 1996." In 1970's, more than ten habitats of *L. angelina* in Hyogo Prefecture were known, but actually only Sara Pond seems to bear a population. Even this habitat is threatened by a local government "development plan". Action has to be taken, to enable survival of the species at Sara Pond.] Address: Nishu, S., 247 Gunge Shonomoto, Mikage-cho, Higashinda-ku, Kobe, Hyogo, 658-0057, Japan. E-mail: Snishu@mx2.nisiq.net
- 2221.** Nishu, S. (1997): Report of the survey trip of the Hyogo Society of Odonatology, Part 2 in 1996. *Sympetrum Hyogo* 4: 18-24. (in Japanese with English summary). ["The Hyogo Society of Odonatology had a survey tour for *Mortonagrion hirosei* visiting Momojima Pond, Kinohira-cho, Hyogo Prefecture on July 20-21. Estimation of the individual number was made through the marking-recapturing method. 100 males were marked and released, and 92 males were captured on the next day including 13 marked ones. The total number of this damselfly inhabiting this pond was estimated to be at the order of 10,000 for the time. Masses of this species were found sleeping at night. Most of them were roosting on stalks at a height of 10 to 20 cm above water-level. [...]"] A list of 41 species recorded in the framework of the survey are listed in a table.] Address: Nishu, S., 247 Gunge Shonomoto, Mikage-cho, Higashinda-ku, Kobe, Hyogo, 658-0057, Japan. E-mail: Snishu@mx2.nisiq.net
- 2222.** Nishu, S. (1997): Report of the survey trip of the Hyogo Society of Odonatology, Part 3 in 1996. *Sympetrum Hyogo* 4: 28-31. (in Japanese with English sum-

summary). ["An immature male *Stylurus nagoyanus* was caught in Mt. Funakoshi, Sayo-cho in 1993. This is the only record of this species in Hyogo Prefecture until today. Immature imagoes of this species are known to migrate to distant places, and we had a survey trip to find the original habitat. One of our members, Mr Inoue, once happened to see a gomphid dragonfly much like this species along Ibo River, hence we had a survey trip to this river on September 8, 1996. The results were not successful, but we recorded 14 species in 6 families including many males and 3 females of *Onychogomphus viridicostus* and 5 males of *Anisogomphus maaki*." (Author) In addition species lists for five localities are given in two tables.] Address: Nishu, S., 247 Gunge Shonomoto, Mikage-cho, Higashinda-ku, Kobe, Hyogo, 658-0057, Japan. E-mail: Snishu@mx2.nisiq.net

2223. Sogame, S. (1997): A male *Sympetrum pedemontanum elatum* with an aberrant wing brown marking. *Sympetrum Hyogo* 4: 14. (in Japanese with English summary). [A male *S. pedemontanum elatum* had a round colourless area in the brown marking on right forewing. This area is thinner than the other parts, and was found broken after the specimen was kept in a triangular paper.] Address: not stated

2224. Wada, N.; Inoue, K. (1997): First record of *Zygomma obtusum* from Kuroshima island, Taketomi-cho, Okinawa Prefecture. *Sympetrum Hyogo* 4: 5-7. (in Japanese with English summary). [A male *Z. obtusum* was caught on Kuroshima Island, Japan, a small oceanic island located between Ishigaki and Iriomote Islands. "This crepuscular insect was found at 20:00 - 21:00 attracted to a fluorescent lamp in a passage of a cottage in Marine Research Center. This species had been found only on North and South Borodino Islands in Japan, but in 1996 a female was caught by Mr Akira Nishida on June 23 at Nishi-funatsukibashi, Iriomote Island (Nishida, A. 1996) and males and females were captured by Mr Osamu Tabata on June 30 to July 2 at Taisho Pond, Iriomote Island [...]. Thus this is the third record outside N. and S. Borodino Islands. Oguma, K. recorded a male of this species in 1915. The specimen is labelled "Okinawa, VIII, 1902", but no additional material had been found from Okinawa Main Island, and many males and females have been found after 1958 on N. and S. Borodino Islands which are in Okinawa Prefecture, thus the Oguma's specimen had been supposed to have come from N. or S. Borodino Island. The new discovery of this oceanic species from islands outside N. and S. Borodino Islands brought a discussion on the possibility to be found on Okinawa Main Island. Another point to be mentioned is that this male was attracted to an artificial light. Lieftinck (1954) writes "Females often attracted to light", and it is advised to try "light trap method" for further studies." (Authors)] Address: Inoue, K., 5-9 Fuminosato 4-chome, Abeno-ku, Osaka 545, Japan

2225. Althmoos, M. (1998): Möglichkeiten und Grenzen des Einsatzes regionalisierter Zielarten - dargestellt am Modellbeispiel des Biosphärenreservates Rhön. *Laufener Seminarbeiträge* 8/98: 127-156. (in German). [This

is an extensive and sound discussion of methods and fundamentals for the use of a regionalised target species concept. Odonata are considered as good target species; in the studied area *Calopteryx virgo* / *C. splendens*, *Gomphus vulgatissimus*, *Coenagrion hastulatum*, *Lestes dryas*, *Aeshna juncea*, *A. subarctica* / *Soma-tochlora arctica*, *Cordulegaster boltonii*, and *Sympetrum flaveolum* are important umbrella species for nature conservation measures.] Address: Althmoos, M., Projekt "Zoologischer Artenschutz im Biosphärenreservat Rhön", Bauerbacher Str. 46, D-35043 Marburg, Germany.

2226. Aoki, T.; Nishu, S. (1998): A survey for discovery of new breeding sites colonized by *Ictinogomphus pertinax* (Selys) in southwestern Hyogo Prefecture. *Sympetrum Hyogo* 5: 16-20. (in Japanese with English summary). [*I. pertinax* extends its range northeastward in Japan. It was found at Ushimado in eastern part of Okayama Prefecture in 1980, and at Akashi in southwestern part of Hyogo Prefecture in 1987. "In 1994, the senior author found a new locality at Kakogawa, some 25 km northwest to Akashi. The area from Ushimado to Kakogawa has been left unrecorded for this species." On 18 August 1997 five members of the Hyogo Society of Odonatology tried to fill the blank. Eleven localities - with splendid dragonfly populations - were visited, but they failed to discover this southern gomphid species. The results of the survey are compiled in a table including 24 species.] Address: Aoki, T., Rokko Island High School, Naka 4-chome, Koyo-cho, Higashinada-ku, Kobe, 658-0032, Japan. E-mail: taoki@ma3.justnet.ne.jp

2227. Aoki, T. (1998): Odonata fauna of Kobe City, Part 7. (Platycnemididae, Epiophlebiidae, Petaluridae). *Sympetrum Hyogo* 5: 21-22. (in Japanese with English summary). [*Platycnemis foliacea sasakii*, *Copera annulata*, *Epiophlebia superstes*, and *Tanypteryx pryeri* are recorded in Kobe City. "*E. superstes* was found at Arima in Mt. Rokko area on June 12, 1996 (two larvae), on July 9, 1996 (two larvae) and on May 25, 1997 (oviposition incisions). These records are rediscoveries after 60 years for this area."] Address: Aoki, T., Rokko Island High School, Naka 4-chome, Koyo-cho, Higashinada-ku, Kobe, 658-0032, Japan. E-mail: taoki@ma3.justnet.ne.jp

2228. Fincke, O.M. (1998): The population ecology of *Megaloprepus coerulatus* and its effect on species assemblages in water filled tree holes. In: Dempster, J.P. & I.F.G. Mclean (Eds.): *Insect populations: in Theory and Practice*. Kluwer Academic Publishers. London: 391-416. (in English). ["Although its larvae are restricted to tree holes, the influence of *M. coerulatus* extends beyond that microhabitat via its effects on intraguild predators, such as *Dendrobates* and *Toxorhynchites*, that also breed in other phytotelmata. The evidence to date suggests that the abundance of *M. coerulatus* is primarily affected by biotic factors during the larval stage, specifically obligate sibicide and cannibalism followed by intraguild predation. Within this competitive framework, at a local level, population size should be affected by abiotic factors. The number of generations a tree hole can support annually reflects rainfall patterns as well as nutrient input (e.g. leaf and fruit detritus), which influences growth rate and adult body size via increased prey productivity. Among forests, body size probably reflects evolutionary responses to differences in tree-hole nutrient levels. Finally, changes in forest

composition would affect the abundance of *Megaloprepus* because tree holes are non-randomly distributed with respect to tree species. There is no evidence that adult *Megaloprepus* are limited by the availability of prey (i.e. spiders) or by predation. Their ability to find tree-hole oviposition sites may be more limiting than their capacity to produce excess eggs. However, in seasonal forests, persistence of *Megaloprepus* depends on adults surviving the dry season. Adults are also the dispersal stage. Because *Megaloprepus* avoids large, man-made clearings, it may be particularly vulnerable to habitat fragmentation." (Author)] Address: Finke, O.M., Dept Zool., Univ. Oklahoma, 730 Van Vleet Oval, Room 314, Norman, OK 73019, USA. E-mail: fincke@ou.edu

2229. Franz, D. (1998): Das Blaukehlchen. ISBN 3-89104-582-4: 140 pp. (in German). [Odonata rarely seem to be the prey of *Luscinia svecica* (Aves). On page 104 a few records are compiled, among them a note on a picture of a male *Libellula depressa* preyed by the Bluethroat.]

2230. Grosser, N.; Rötzer, B. (1998): Realisierbarkeit eines Zielartenkonzepts auf regionaler Ebene. - Ergebnisse einer Projekt-Diskussion im Bereich der Gemeinde Friedenfels, Landkreis Tirschenreuth (Oberpfalz). Laufener Seminarbeiträge 8/98: 121-126. (in German). [A students project group discussed - in the framework of the realisation of the communal landscape plan of the community Friedenfels, Bavaria - the possibilities to use target species for a sound realisation of measures. Some theoretical thoughts to select target species are presented. These species are discussed on the in reality existing level of restrictions among a community and acceptance of nature conservation measures by its population. Among the target species without any conflict potential are *Calopteryx virgo*, *C. splendens*, and *Cordulegaster boltonii*.] Address: Grosser, N., Fachhochschule Erfurt, Fachbereich Landschaftsarchitektur, Leipziger Str. 77, D-99085 Erfurt, Germany. 2231. Marabini, J. (1998): Die Rolle von Ziel- und Leitarten für die Renaturierung von Mooreichen - am Beispiel eines ABSP-Projektes im Aischgrund. Laufener Seminarbeiträge 8/98: 165-168. (in German). [Activities of human beings in ancient times e.g. to create and to run carp ponds provided suitable habitats for some specialized plants and animals. This paper discusses activities to manage abandoned ponds for nature conservation purposes. Examples given are the plant genus *Utricularia*, the moor frog (*Rana arvalis*), and *Leucorrhinia dubia*, *L. rubicunda*, and *L. pectoralis*.] Address: Marabini, J., Landratsamt Erlangen-Höchststadt, Schloßberg 10, D-91315 Höchststadt/Aisch, Germany

2232. Matsuda, I. (1998): Memories of the late Mr. Hiroshi Itoh. *Sympetrum Hyogo* 5: 2-3. (in Japanese with English summary). ["Mr. Hiroshi Itoh passed away on July 14, 1997 at the age of 62. He was a very kind person, and he had often guided us to many good habitats of various species. An oral tumour was found in October, 1995, and the operation was carried out successfully. But it metastasized to the lung, and he had operations during July to October, 1996. He had recovered well, and he attended field meetings and the Celebrating Party of Mr. Y. Miyatake held on June 1, 1997. In early July he was hospitalised again, and could not re-

cover this time. He, with his kind and heartily personality, will live in our heart forever." (Author)] Address: not stated

2233. Müller, J. (1998): Die Libellenfauna (Insecta: Odonata) der Naturschutzgebiete Mahlpfuhler Fenn, Jävenitzer Moor und Benitz des Tanger-Gebietes und der Altmark-Heiden in Sachsen-Anhalt. *Abh. Ber. Mus. Naturk. Magdeburg* 20: 3-18. (in German with English summary). [The odonate fauna of two bog moors (Mahlpfuhler Fenn, Jävenitzer Moor) and a gravel pit (Benitz), Sachsen-Anhalt, Germany, is documented in detail. The species are arranged according to ecological groups of habitat preference and the zoogeographical distribution. The species list accounts 42 species, 19 of them are commented.] Address: Müller, J., Frankefelde 3, 39116 Magdeburg, Germany. E-mail: Fau-nOek.Jmueller@t-online.de

2234. Muraki, A.: (1998): Record of dragonflies of Kohama Island, Yaeyama, Okinawa Pref. made by the late Mr. Hiroshi Itoh. *Sympetrum Hyogo* 5: 4. (in Japanese with English summary). ["The late Mr. Hiroshi Itoh visited Kohama Island on May 13, 1996, but he has not reported on the results. He found seven species including *Ictinogomphus pertinax*, *Brachythemis contaminata*, *Pseudothemis zonata*, and *Tholymis tillarga* which are new to this island." (Author)] Address: not stated

2235. Nishu, S. (1998): A supposed hybrid between *Anax parthenope julius* and *A. n. nigrofasciatus* emerged from a bred larva. *Sympetrum Hyogo* 5: 31-33. (in Japanese with English summary). ["A final instar larva of a suspicious species was caught at a dragonfly pond in Amagasaki No.3 Power Plant of Kansai Electric Power Co. on August 9, 1997. It resembled that of *Anax n. nigrofasciatus*, but larvae of this species are univoltine which generally reach the final instar much later. It was brought home, and emerged on September 11, the same year. It is a male *Anax* which shows three features intermediate between *A. parthenope julius* and *A. n. nigrofasciatus*, seven features like the latter while a feature like the former. Thus it is most probably a hybrid between these two species, and the second record of emerged hybrids in this combination of species." (Author)] Address: Nishu, S., 247 Gunge Shonomoto, Mikage-cho, Higashinda-ku, Kobe, Hyogo, 658-0057, Japan. E-mail: Snishu@mx2.nisiq.net

2236. Nishu, S. (1998): A survey report of *Libellula angelina* Selys in Hyogo Pref., 1997. *Sympetrum Hyogo* 5: 5-8. (in Japanese with English summary). ["*L. angelina* was seen in many places in Hyogo Pref. until several years ago, but Sara Pond, Fukuden-cho, Ono City is the only known habitat for this endangered species in this prefecture at present. Members of the Hyogo Society of Odonatology visited this pond on April 29 and May 11, and two additional localities on April 29." Two males were found in May at Sara Pond. The environmental condition of the habitat seem to have recovered and be comparable with that formerly existing. In spite of this first side indication, low abundance demonstrates that at least one ecological factor must prevent the species to settle on this habitat.] Address: Nishu, S., 247 Gunge Shonomoto, Mikage-cho, Higashinda-ku, Kobe, Hyogo, 658-0057, Japan. E-mail: Snishu@mx2.nisiq.net

2237. Nishu, S. (1998): A survey report of *Mortonagrion hirosei* Asahina in Hyogo Pref., 1997. *Sym-*

petrum Hyogo 5: 9-11. (in Japanese with English summary). [M. hirosei was surveyed during 20-21 July 1997 at three localities in the northern part of Hyogo Prefecture, Japan. Abundance was higher than the years before (Counts of sleeping specimens). But contrary to the previous year the specimens were found sleeping rather dispersed and not congregated. A list of 23 additional species found at the four localities is appended.] Address: Nishu, S., 247 Gunge Shonomoto, Mikage-cho, Higashinda-ku, Kobe, Hyogo, 658-0057, Japan. E-mail: Snishu@mx2.nisiq.net

2238. Nishu, S. (1998): First discovery of the locality of *Stylurus nagoyanus* (Asahina) in Hyogo Prefecture. *Sympetrum Hyogo* 5: 12-15. (in Japanese with English summary). [A male *S. nagoyanus* was found in Hyogo Pref. in 1993, but the larval habitat was unknown. Izushi River in the northern part of this prefecture turned out to be a reproductive habitat of the species: 3 males, 1 female and 8 larvae were caught on 21 July 1997, and 2 males and 1 female were caught on September 21. The habitat seems to provide suitable conditions, and was dwelled by one of the Japanese Red Data Book species, *Macromia daimoji* too. 23 additional species recorded at this locality are listed in a table.] Address: Nishu, S., 247 Gunge Shonomoto, Mikage-cho, Higashinda-ku, Kobe, Hyogo, 658-0057, Japan. E-mail: Snishu@mx2.nisiq.net

2247. Bezdecka, P. (1999): The current state of dragonfly research in the Bělé Karpaty (White Carpathians), Czech Republic. In: Hanel, L. (Ed.): *Vazky 1999. Sborník referátu z mezinárodního semináře konaného v Podblanickém ekocentru CSOP ve Vlasimi* 6.-7.3.1999. ISBN 80-86327-00-0: 69-72. (in Czech with English summary). [List of 36 Odonata (37 taxa) from the Carpathian mountains resp. the Region of the Czech - Slovakian border.] Address: Bezdecka, P., Správa CHKO Bílé Karpaty, Nádrázní 318, CZ 76326 Luhacovice, Czech Republic

- 2248.** Carl, M. (1999): Biomonitoring zur Ökologie und Renaturierung anthropogen veränderter Lebensräume des bayerischen Salzachauen-Ökosystems von Freilassing bis zur Mündung in den Inn. *Berichte der Akademie für Naturschutz Laufen* 23: 121-131. (in German). [In the framework of a revitalisation project of the river Salzach, Bavaria, Germany, *Thecagaster bidentata* was considered a good bioindicator for assessing success of measures undertaken. This assumption is based on the known distinct factors characterising the habitat of the species. Going ahead with the revitalisation measures *T. bidentata* turned out to be unsufficiently suitable to indicate and assess the middle to large scale measures. Even natural factors may influence the habitat of larvae, while an indicator for revitalisation measures has to react on a causal scale: The species is a good indicator for micro habitats, but not for the ecosystem of the alluvium. Thus, it was excluded from the list of bioindicator species that will be used to assess the success of the revitalisation in future.] Address: Carl, M., Gollenbergstr. 12, D-82299 Türkenfeld, Germany
- 2249.** Cempírek, J. (1999): The dragonflies of the town České Budjovice I. (southern Bohemia). In: Hanel, L. (Ed.): *Vazky 1999. Sborník referátu z mezinárodního semináře konaného v Podblanickém ekocentru CSOP ve Vlasimi 6.-7.3.1999.* ISBN 80-86327-00-0: 47-52. (in Czech with English summary). [Two localities (forest lake, gravel-pit) in the environs of České Budjovice, Czech Republic were surveyed for their odonate fauna. 33 excursions between 1985 and 1988 are documented in detail in a "present-absent-table" for the forest lake and the gravel pit (5 excursions).] Address: Cempírek, J., Vidov 37, 370 07 České Budjovice, Czech Republic

15. (in Czech with extensive English summary). [The paper outlines the current status of odonatological research in the Czech Republic starting with the first studies published in the end of the 19th century. In 1994 a National Biodiversity projekt "Dragonflies" was started, which enforced recent odonatological research. As a aim of this project, handbooks were released, and educating of persons interested in Odonata was started. The first results of these endeavours were presented in 1999 in the framework of an odonatological meeting in Vlasim. Assessed on the basis of 100 km² squares, in the end of the 20th century odonatological information of app. 1/3 of all squares is available. Middle term aims of odonatological studies are the preparation of a Red List and realising an atlas of the Czech Odonata.] Address: Hanel, L., Správa chránené krajinné oblasti Blaník, 257 06 Lounovice pod Blaníkem 8, Czech Republic. E-mail: blanik@schkocr. cz
- 2258.** Hatanaka, N. (1999): Report of the survey trip of the Hyogo Society of Odonatology, Part 4 in 1998. *Sympetrum Hyogo* 6: 33-35. (in Japanese with English summary). [The rare *Stylurus nagoyanus* (imagoes), and *Macromia daimoji* (larvae) were observed on 6 September 1998 at Izushi River, Izushi-cho, Hyogo Prefecture, Japan. A table with additional records of 18 taxa is appended.] Address: not stated
- 2259.** Hlásek, J. (1999): The dragonfly *Nehalennia speciosa* - a new species in the Czech Republic. In: Hanel, L. (Ed.): *Vazky 1999. Sborník referátu z mezinárodního semináře konaného v Podblanickém ekocentru CSOP ve Vlasimi 6.-7.3.1999.* ISBN 80-86327-00-0: 75-76. (in Czech with English summary). [*N. speciosa* is described from the boggy fen "Kramafka" (Czech mapping square 6854). The locality is situated in the Protected Landscape Area Trebonsko (South Bohemia). In total 37 mostly freshly hatched specimens (17 males and 20 females) were found on 14. July 1998. The habitat is characterized by the plant community of *Caricetum rostratae*. Co-occurring species are *Aeshna juncea*, *Calopteryx splendens*, *Coenagrion hastulatum*, *C. puella*, *Cordulia aenea*, *Erythromma najas*, *Ischnura elegans*, *Lestes sponsa*, *Leucorrhinia rubicunda*, *Libellula quadrimaculata*, *Platycnemis pennipes*, *Pyrrosoma nymphula*, *Sympecma fusca*, *Sympetrum danae*, and *S. vulgatum*.] Address: Hlásek, J., 39181 Veseli nad Luznici I/308, Czech Republic
- 2260.** Huber, A. (1999): Data on the dragonfly (Odonata) fauna of the Landscape Protection Area of Middle-Tisza and its surroundings. *Studia odonotol. hung.* 5: 29-46. (in Hungarian with English summary). [Hungaria; between April 1994 and November 1996, 38 species were collected at 51 localities. Records of *Coenagrion pulchellum*, *Erythromma najas*, *E. viridulum*, *Sympecma fusca*, *Stylurus flavipes*, *Epitheca bimaculata*, *Lestes virens*, *Brachytron pratense*, *Sympetrum depressiusculum*, *S. flaveolum*, *S. meridionale*, and *S. pedemontanum* should be noted.] Address: Huber, A., Department of Ecology, Kossuth L. This is an introduction into dragonfly biology directed to a general reader. The paper is illustrated with some black and white drawings, and a portrait of Prof. Dr. Jos Moens.] Address: Moens, J., Dept. S.B.M., Limburgs Universitair Centrum, Universitaire Campus, B-3610 Diepenbeek, Belgium
- 2267.** Moriyasu, T. (1999): Larvae of *Macromia daimoji* first caught at Chikusa River, Hyogo Prefecture. *Sympetrum Hyogo* 6: 8. (in Japanese with English summary). [Two final instar larvae of *M. daimoji* were caught on 3 January 1998 in the Chikusa River, Ako City, Hyogo Prefecture, Japan.] Address: not stated
- 2268.** Naraoka, H. (1999): On the *Forcipomyia* (*Pterobasca*) *tokunagai* Oka and *Asahina* (Diptera: Ceratopogonidae). *Journal of natural History of Aomori* 4: 17-21. (in Japanese (Translation by H. Naraoka and N. Ishizawa)). [The paper compiles published records of the ceratopogonid *F. (Pterobasca) tokunagai* parasitizing

Japanese Odonata. The author adds some new material collected between 1985 and 1998 (*Mnais pruinosa* Selys 1853, *Davidius moiwanus* (Okumura 1935), *Davidius fujiana* Fraser, 1936, *Sympetrum darwinianum* (Selys 1883), *S. frequens* (Selys 1883), *S. eroticum* (Selys 1883), *S. infuscatum* (Selys 1883), *Trithemis aurora* (Burmeister 1839), and *Pseudothemis zonata* Burmeister, 1839). More recently published assumptions, Ceratopogonidae would stuck Odonata during emergence are rejected. The author didn't find just emerged dragonflies parasitised, but parasitism on mature dragonflies was recognized. Parasitism is interpreted to depend on congruence of flight period of the ceratopogonid and odonate specimens.] Address: Naraoka, H., 36-71, Aza-Motoizumi, Fukunoda, Itayanagi-cho, Kitagun, Aomori Prefecture, 038-3661, Japan

2269. Nishu, S. (1999): Report of the survey trip of the Hyogo Society of Odonatology, Part 3 in 1998. *Sympetrum Hyogo* 6: 29-32. (in Japanese with English summary). [Momojima Pond, Kinosaki-cho Hyogo Prefecture, Japan was visited during July 19-20, 1998. The society carried out annual survey trips for *Mortonagrion Hirosei* since the first discovery in 1992. It is planned to construct a sewage treatment plant at Kinosaki-cho, and a part of the habitat has to be filled up. Construction works had started already. *M. Hirosei* inhabits also the part to be destroyed. Some larvae of this species were found together with the larvae of *Ischnura senegalensis* which is a strong predator on the former species. Two additional habitats of *M. Hirosei* were visited. *Stylurus nagoyanus*, *Onychogomphus viridicostus*, and *Macromia daimoji* have been found at Izushi River.] Address: Nishu, S., 247 Gunge Shonomoto, Mikage-cho, Higashinda-ku, Kobe, Hyogo, 658-0057, Japan. E-mail: Snishu@mx2.nisq.net

2270. Nishu, S. (1999): *Stylurus ocellatus* first found in Hyogo Prefecture. *Sympetrum Hyogo* 6: 3. (in Japanese with English summary). [The species was caught on 18 July 1998 at the seashore of Suma, Kobe City, Japan. It is the 98th Odonata reported from the Hyogo Pref., and the 90th in Kobe City.] Address: Nishu, S., 247 Gunge Shonomoto, Mikage-cho, Higashinda-ku, Kobe, Hyogo, 658-0057, Japan. E-mail: Snishu@mx2.nisq.net

2271. Oka, I. (1999): Report of the survey trips of the Hyogo Society of Odonatology, Part 1 and 2 focused to *Libellula angelina*. *Sympetrum Hyogo* 6: 23. (in Japanese with English summary). [A total of 18 members of the Society failed on 3 and 24 May 1998 to discover this endangered species in Sara Pond, Ono City, Hyogo Prefecture, while between 1991-1994, about 200-300 immature specimens were observed every year at both Yude Pond in Kobe City and Sara Pond in Ono City. The species disappeared in 1995 at the former pond, and in 1997 at the latter pond. The law regulation - started in 1993 - couldn't stop the extinction of *L. angelina*. A brief note is made to longevity of a specimen marked at emergence (53 days). Additional species recorded in the framework of the survey are listed in appended tables.] Address: not stated

2272. Olajos, P.; Kiss, B. (1999): Data on the dragonfly (Odonata) fauna of the north-eastern part of the Hungarian flatland Tiszai-Alföld. *Studia odonatol. hung.* 5: 15-28. (in Hungarian with English summary). [A total of 43 species was collected at 54 localities in the eas-

tern part of Great Hungarian Plain. Records of *Leucorrhinia caudalis*, *L. pectoralis*. and *Aeshna cyanea* are considered of special regional interest. In addition, *Brachytron pratense*, *Aeshna viridis*, *Stylurus flavipes*, *Ophiogomphus cecilia*, *Epithecica bimaculata*, and *Sympetrum depressiusculum* should be noted.] Address: Olajos, P., Hortobágy Nemzeti Park, Igazgatóság, H-4024 Debrecen, Sumen u.2, Hungary

[Compilation and mapping of records of *G. vulgatissimus* in the region Oberfranken, Bayern, Germany. In addition records of the regionally rare *Onychogomphus forcipatus* are dealt with.] Address: Strätz, C., Alexanderstr. 5, D-95444 Bayreuth, Germany. E-mail: chris.straetz@bth.de

2274. Sálek, P. (1999): The faunistic research of dragonflies (Odonata) in three marshes in the district Vsetín (north Moravia, Czech Republic). In: Hanel, L. (Ed.): *Vazky 1999. Sborník referátu z mezinárodního semináře konaného v Podblanickém ekocentru CSOP ve Vlasimi 6.-7.3.1999.* ISBN 80-86327-00-0: 65-68. (in Czech with English summary). [A total of 22 species were recorded at three localities. Some management measures are proposed to improve situation for Odonata.] Address: Sálek, P., Visnovce 1093, CZ-746824 Hulín, Czech Republic

2275. Sasamoto, A.; Inoue, K. (1999): *Anax guttatus* caught at Aonogahara, Hyogo Prefecture. *Sympetrum Hyogo* 6: 36-37. (in Japanese with English summary). ["Sasamoto visited Sara Pond and Hira Pond in Aonogahara, Hyogo Prefecture on October 10, 1998, and caught 1 male and 1 female *Anax guttatus*. Next day Inoue visited Sara Pond, not knowing the former's findings, and caught 1 male of the same species. In both cases several males of this tropical aeshnid species were observed patrolling rapidly in search of females along the shore, and Sasamoto found a female ovipositing solitarily. This female was brought home, and laid ca 2,000 eggs in two days. Eggs started to hatch 15 days after oviposition under the room temperature of about 20°C."] Address: Inoue, K., 5-9 Fuminosato 4-chome, Abeno-ku, Osaka 545, Japan

2276. Sogame, S. (1999): Odonate fauna of Kohzuki and the neighbouring localities in Sanda City, Hyogo Prefecture. *Sympetrum Hyogo* 6: 4-7. (in Japanese with English summary). [Between 1996 and 1998, 47 species were recorded. The survey stressed on the fauna of sunny irrigation ponds (For riverine Odonata see Sogame 1998).] Address: not stated

2277. Yagi, T. (1999): Collection records of *Anax guttatus* in Sanda City, Hyogo Prefecture. *Sympetrum Hyogo* 6: 38. (in Japanese). [Two records of *A. guttatus* are communicated.] Address: not stated

2278. Yagi, T. (1999): Poster exhibition at the 9th Dragonfly Citizen Summit in Kobe. *Sympetrum Hyogo* 6: 39. (in Japanese). [A poster of *Mortonagrion Hirosei* without further explanations presented on 23 August 1998 is documented.] Address: not stated

2000

2279. Alvo, R.; Campbell, D. (2000): Pre-fledged Common Loon, *Gavia immer*, on an acidic lake dies with food bolus in esophagus. *Can. Field-Nat.* 114(4): 700-702. (in English). ["A moribund pre-fledged Common Loon (*Gavia immer*) with a bulge in its throat was collected from acidic Silvester Lake. It died soon afterwards. Dissection of the bird revealed that the bulge was a food bolus containing Yellow Perch (*Perca flavescens*), dragonfly larvae (*Somatochlora cingulata* and *Aeshna* sp.), crayfish (*Cambarus robustus*) and whirligig beetles (*Dineutus* sp.). We suggest this bird may have swallowed a large fish that punctured the esophagus on its way to the proventriculus, causing peristalsis to cease. Food subsequently swallowed could not move beyond the esophagus, thus forming the bolus. The loon may have swallowed the large fish because food of suitable size for a bird of that size was in short supply due to the lakes acidity." (Author)] Address: Alvo, R., 58 Rue Parulines, Hull, PQ J9A 1Z2, Canada

2280. Bánkuti, K.; Devai, G.; Miskolczi, M. (2000): Data on the dragonfly (Odonata) fauna of the Aggtelek region based on a survey of exuvia. *Studia odonotologica*. 6: 21-25. (in Hungarian with English summary). [In 1993, 18 odonate species (exuviae) were collected at 17 localities in Aggtelek National Park, N-Hungary. The list includes *Coenagrion ornatum* and *Ophogomphus cecilia*.] Address: Devai, G., Department of Ecology, Kossuth L. University, H-4010 Debrecen, P.O. Box 71, Hungary

2281. Bechly, G. (2000): A new fossil damselfly species (Insecta: Odonata: Zygoptera: Coenagrionidae: Ischnurinae) from Dominican Amber. *Stuttg. Beitr. Naturk. (B)* 299: 1-9. [*Ischnura velteni* sp. n. is described from an unknown locality, Dominican Republic, Eocene-Miocene (female holotype: Do-5687, in SMNS, Stuttgart). It represents the first fossil record of this genus, and it is one of the smallest known fossil Odonata. Its systematic position is outlined and discussed.] Address: Bechly, G., Staatliches Museum für Naturkunde, Abt. Paläontologie, Rosenstein 1, D-70191 Stuttgart, Germany. E-mail bechly@gmx.de

2282. Bedjanic, M.; Pirnat, A. (2000): A contribution to the knowledge of the dragonfly fauna (Insecta, Odonata) of the Vipava valley, W-Slovenia. *Natura Sloveniae* 2(2): 29-45. (in Slovene with extensive English summary). ["An annotated list of 32 dragonfly species collected at 27 localities during the 1994-2000 period is given. Three species, viz. *Ceragrion tenellum*, *Anax parthenope*, and *Libellula fulva*, are new for the investigated area. The records of *Coenagrion ornatum*, *Cercion lindenii*, *Cordulegaster heros*, *Somatochlora flavomaculata*, and *Orthetrum c. coerulescens* are also briefly commented as they deserve attention from zoogeographical or nature conservation point of view. A list of 44 dragonfly species, hereto reported from the Vipava valley with its surroundings, is compiled and an odonatological bibliography of the investigated area is presented." (Authors)] Address: Pirnat, Alja, Bioloski Institut, ZRC

2283. Beutler, H. (2000): Landschaft in neuer Bestimmung. Russische Truppenübungsplätze. Findling. Neuenhagen. ISBN 3-933603-11-0. 192 pp. (in German). [Texts directed to a public interested in nature, and intrusive colour photos elucidate the outstanding importance of the former military training areas of the Russians in Germany for nature conservation purposes. In an appendix, 12 of these training areas are characterised in detail. As far as odonatological data are available, these are compiled. Of special interest are *Coenagrion mercuriale*, *Nehalennia speciosa*, *Aeshna viridis*, *Epithea bimaculata*, *Leucorrhinia albifrons*, *L. caudalis*, *L. pectoralis*, and lake-populations of *Cercion lindenii* and *Onychogomphus forcipatus*.] Address: Beutler, H., Kirschallee 35, D-15848 Stemmen, Germany

2284. Bezdecka, P. (2000): Dragonflies (Odonata) of the Chriby Highlands (Moravia, Czech Republic). In: Hanel, L. (Ed.): *Vazky 2000. Sborník referátu III. celostátního semináře odonatologu, který se konal v Chráněné krajinné oblasti Trebonsko 15.-18.6.2000*. Vlasim. ISBN 80-86327-12-4: 154-161. (in Czech with English summary). [The survey of 47 localities resulted in 35 Odonata, which are briefly commented. The region seems to be a hot spot for the rare *Cordulegaster boltonii* and *Thecagaster bidentata* in the Czech Republic.] Address: Bezdecka, P., V.Vaculky 994, CZ-68605 Uherské Hradiště, Czech republic. E-mail: pbezdecka@iol.cz.

2285. Bösel, A. (2000): Hat *Aeshna subarctica* (Walker 1908) in Nordostdeutschland eine Überlebenschance? *Natur und Landschaft* 76(6): 257-261. (in German with English summary). ["The exuvia of *A. subarctica* have been recorded since 1995 in the Gölde nitzer Moor mire in the German regional state of Mecklenburg / Western Pomerania. Occurrence declined within 6 years from 322 to 12 hatched individuals. This is associated with the simultaneously observed disappearance of *Sphagnum* ssp. The loss of *Sphagnum* plants is due to intensive drainage and elevated nutrient availability. In the Horster Moor mire, a presumably extinct population re-established itself after restoration measures as an abundant and autochthonous population. Restoration of the Horster Moor site, where peat had previously been extracted industrially commenced in 1986 by water-logging this ombrogenous bog. At first, *Sphagnum* cover developed only slowly. Finally, however, in shallow flooded areas a stand of *Eriophorum* ssp. with mossy bog ponds developed. In areas where manual peat-digging was practised, too, flooded *Sphagnum* grew again after the water level rose. Consequently, after 14 years of recultivation, *A. subarctica* has re-established itself with a major autochthonous population. However, this population remains endangered by eutrophication of its larval waters." In Western Pomerania 9 additional localities with records of *A. subarctica* are known, which are in total severely threatened. The author therefore takes at medium-terms the extinction of this dragonfly in north-eastern Germany as likely. Comment of M. Schorr: *A. subarctica* is not occurring in Germany, the correct taxa is *Aeshna subarctica elisabethae* Djakonov, 1922.] Address: Bösel, A., Vasenbusch 15, D-18337 Gresenhorst, Germany. E-mail: andre.boensel@gmx.de

2286. Burkart, G.; Burkart, W. (2000): Två nya trollsländearter för Gotland! *Körkmacken* 27: 14-15. (in Swedish). [Two new Odonata for Gotland. *Sympecma fusca* and *S. paedisca* have been discovered in late April 2000 on the island of Gotland, Sweden. Both species are new for the island, and *S. paedisca* never has been observed prior 2000 in Sweden. Hence, a new Swedish name "Sibirisk vinterflickslända" is proposed.] Address: Burkardt, G. & W., Am Emel 7, D-27412 Wilstedt b. Bremen, Germany

2287. Burkart, W. (2000): Trollsländefynd, *Aeshna mixta*. *Körkmacken* April 2000: 3. (in English with Swedish notes). [This is a faunistic note on a record of *A. mixta* which is new to the Island of Gotland, Sweden. Locality information are very detailed, but the date of record (probably 1999) is missing.] Address: Burkardt, W., Am Emel 7, D-27412 Wilstedt, Germany.

2288. Burmeister, E.-G. (2000): Der Einsatz von Bti-Präparaten zur Stekmückenbekämpfung - Hintergründe, Risiken und Bedenken. *Berichte der Akademie für Naturschutz, Laufen* 24: 125-136. (in German with English summary). ["In the last years in Germany, especially in Bavaria, mosquito control has come into high demand. Mosquito populations, within their natural turnover have not increased, but the contact zones between mosquito and man have. Recreational activities, sports and sports fields, camping sites, restaurants etc. are entering areas like alluvial flood plains or flooded areas of lakes dominated by mosquitoes. The same applies to residential areas. The extract from *Bacillus thuringiensis israelensis* (Bti) was developed for biological pest-control (endo-toxin) effective specifically against mosquitoes (Culicidae) and black-flies (Simuliidae), according to assurances by the producer and persons with interests in using Bti. The difficulties with Bti applications are demonstrated here. Bti has also been used against non-biting midges (Chironomidae) in the impoundments of the Danube river (Bavaria). This study documents further that other animals in small ponds are also killed. Together with the primary effect on target and non-target organisms also the secondary effect on higher levels in the food chains, such as birds and bats, is to be emphasised: the reduction of the masses of mosquitoes and midges, the basis for their nutrition. Pest control with Bti is an intervention in the biocoenotic systems of valuable habitats. In the present work, the biology of mosquitoes, their control with modern methods and aspects, the effect on animal life in habitats and the studies on the success of the pest-control are documented. The most problematic applications of this special insecticide in protected areas are discussed. Some alternative methods for prevention against mosquitoes are given." (Author) In table 1 literature data on impact of Bti on taxa is compiled. Short time studies - up to 1 month - on Odonata (*Calopterygidae* spp., *Ischnura elegans*, *Aeshna* sp., *Sympetrum striolatum*, *Orthetrum brunneum*) didn't find any influence on the taxa. In two studies population density of *Coenagrionidae* and *Anax* sp. was reduced.] Address: Burmeister, E.-G., Zoologische Staatssammlung, Münchhausenstr. 21, D-81247 München, Germany

2289. Catling, P.M.; Jones, C.D.; Pratt, P. (Eds) (2000): Ontario Odonata, vol. 1. In: Catling, P.M., C.D. Jones & P. Pratt (Eds): Ontario Odonata, vol. 1. Toronto Entomologist's Association, Toronto, Ontario. 153 pp. (in English). [This is the first volume of a series devoted

to the Ontario (Canada) Odonata. Plenty odonatological contributions - as far as they are "scientific papers" they are abstracted in OAS 9 - are published. The issue contains some additional organisational information and comments as follows: "Ontario Odonata Projects", "News: 1. A new species of *Neurocordulia* (Odonata: Anisoptera: Corduliidae) from eastern North America", 2. Damselflies and dragonflies (Odonata) of Ontario: resource guide and annotated list, and 3. A field guide to the Dragonflies and Damselflies of Algonquin Provincial Park". "Notice to contributors" introduces and organises the Ontario Odonata Survey. An index of 1999 Ontario species closes the impressive contribution to the knowledge of North American Odonata.] Address: Alan J. Hanks, 34 Seaton Drive, Aurora, Ontario, Canada L4G 2K1. E-mail: A.Hanks@aci.on.ca

2290. Catling, P.M.; Jones, C.D.; Pratt, P. (2000): Introduction to the 1999 Ontario Odonata Summary Records. In: Catling, P.M., C.D. Jones & P. Pratt (Eds): Ontario Odonata, vol. 1. Toronto Entomologist's Association, Toronto, Ontario: 54-145. (in English). [29 odonatologists contributed to the Ontario odonate survey. The data are presented in a table giving information on species, county, location, latitude and longitude of localities, collecting date, collector, and status (imago, larva); the table includes 3612 records. In addition, information of weather conditions in 1999 and trends, analyses and notable records of selected species are given. Special emphasis is given to *Anax junius*, *Epithea canis*, and *Sympetrum vicinum*] Address: Catling, P.M., 2326 Scrivens Drive, R.R. 3, Metcalfe, Ontario K0A 2P0, USA. E-mail: brownell@achilles.net

2291. Cempírek, J. (2000): A contribution to the knowledge of dragonflies (Odonata) of the pond Svárov near Porčí nad Sázavou (Central Bohemia). In: Hanel, L. (Ed.): Vazky 2000. Sborník referátu III. celostátního semináře odonatologu, který se konal v Chráněné krajinné oblasti Trebonsko 15.-18.6.2000. Vlasim. ISBN 80-86327-12-4: 114-117. (in Czech with English summary). [A fishpond - surveyed in 1991 - harbours 18 odonate species.] Address: Cempírek, J., Vidov 37, 370 07 České Budejovice, Czech Republic

2292. Cempírek, J. (2000): Dragonflies (Odonata) of three peat bogs in the Sumava mountains. In: Hanel, L. (Ed.): Vazky 2000. Sborník referátu III. celostátního semináře odonatologu, který se konal v Chráněné krajinné oblasti Trebonsko 15.-18.6.2000. Vlasim. ISBN 80-86327-12-4: 130-143. (in Czech with English summary). [The list of 17 species include *Coenagrion hastulatum*, *Aeshna juncea*, *A. subarctica elisabethae*, *Somatochlora alpestris*, *S. arctica*, and *Leucorrhinia dubia*.] Address: Cempírek, J., Vidov 37, 370 07 České Budejovice, Czech Republic

2293. Chovanec, A. (2000): Dragonflies (Insecta: Odonata) as indicators of the ecological integrity of aquatic systems - a new assessment approach. *Verh. Internat. Verein. Limnol.* 27: 887-890. (in English). [Odonata are considered reliable indicators for assessing the "ecological quality of land-water ecotones and the habitat heterogeneity (e.g. structural components like aquatic vegetation) of water bodies. In view of the new European water management legislation, the development of new practical assessment approaches is essential. One of the major targets of the draft Council Directive establishing a Framework for Community Action in the

Field of Water Policy (EU Water Framework Directive, EUWFD; EUROPEAN UNION COUNCIL 1998) is to classify the ecological status of surface waters in a five-stage system ("high", "good", "moderate", "poor", "bad"). Within this process, investigations of the biological community play a major role. The ecological status of water bodies can be assessed by comparing the status quo of the habitat and a reference condition [...]. The goal of this paper is to demonstrate a new approach to assess aspects of the ecological integrity of standing waters or wetlands by analysing dragonfly communities. The method has been designed to meet the requirements of the new EUWFD" using the dragonfly fauna of the Tritonwasser and Priessnitz Pond (Austria) as case studies.] Address: Chovanec, A., c/o Umweltbundesamt, Spittelauer Lände 5, A-1090 Wien, Austria. E-mail: chovanec@ubavie.gv.at

2294. David, S. (2000): Dragonflies (Insecta-Odonata) of the Slovak-Moravian Carpathians Mountains and the Dolnovazska niva Lea. *Biodiversitas Slovaca* 1: 61-69. (in English with Slovakian summary). [Between 1988 and 1993 21 localities of the Biele Karpaty mountains, Povazie Valley, Myjaské pahorkatiny Hill-land and Dolnovazska niva Lea were surveyed. 28 odonate species including the rare Slovakian *Sympecma fusca*, *Lestes virens*, *L. viridis*, *Ischnura pumilio*, *Anax imperator*, *Epi-theca bimaculata*, *Crocothemis erythraea*, and *Sympetrum pedemontanum* could be traced. The species of different water body types are classified as *Orthetrum - Libellula depressa*-, *Lestes - Sympetrum - Aeshna mixta*- and *Anax - Erythromma najas*- coenoses.] Address: David, S., ÚKE SAV, Akademická 2, SK-94901 Nitra, Slovakia. E-mail: david@pribina.savba.sk

2295. Devai, G.; Miskolczi, M. (2000): Data on the dragonfly (Odonata) fauna of the Aggtelek region based on a survey of adults. *Studia odonatol. hung.* 6: 5-19. (in Hungarian with English summary). [In 1992 and 1993, 40 odonate species (imagos) were collected at 54 localities in Aggtelek National Park, N-Hungary. The species-wise documentation includes *Coenagrion ornatum*, *Ophiogomphus cecilia*, and *Sympetrum depressiusculum*.] Address: Devai, G., Dept of Ecology, Kossuth L. University, H-4010 Debrecen, P.O. Box 71, Hungary

2296. Devai, G.; Miskolczi, M. (2000): Results of biodiversity monitoring on community level by dragonflies (Odonata) in the inundation area (HNBM Programme, Pilot Project) of River Tisza between Tiszabercel and Balsa (NE-Hungary). *Studia odonatol. hung.* 6: 27-54. (in Hungarian with English summary). [This is an attempt to characterise odonate species assemblages on the community level building so called coenoses. The study was realized in the framework of the Hungarian National Biodiversity Monitoring (HNBM)-Programme at six localities in the floodplain of river Tisza. Ox-bows are characterised by a *Ischnura elegans*-*Orthetrum albistylum*-coenoses, marshes by the *Lestes sponsa*-*Sympetrum sanguineum* coenoses. The localities are documented in detail by habitat parameters and photographs as well as by species assemblages.] Address: Devai, G., Department of Ecology, Kossuth L. University, H-4010 Debrecen, P.O. Box 71, Hungary

2297. Di Giovanni, M.V.; Goretti, E.; Larporta, E.; Ceccagnoli, D. (2000): Larval development of *Libellula depressa* (Odonata, Libellulidae) from pools in central Italy. *Ital. J. Zool* 67: 343-347. ["The developmental sta-

ges of the larvae of *L.depressa* were investigated for three years in permanent freshwater pools in central Italy. Eleven instars (F-0 - F-10) of *L. depressa* were discriminated by size and scatter plot. Scatter plots were constructed using the following measurements: labium length, head width, metafemur length, forewing-pad length, and total larval body length. Prolarvae instar was derived by Dyer's law. The mean growth rate coefficient values were about 0.77 for isometric parameters and 0.51 for the forewing-pad allometric parameter. *L. depressa* appeared to be a 'spring species', as defined by Corbet, and the population we studied had a mainly semivoltine life history and, probably, a small proportion of the larvae a univoltine cycle. Eggs showed direct development."] Address: Di Giovanni, M.V., Dipto Biol. anim. & Ecol., Univ. Perugia, Via Elco di Sotto, 1-06123 Perugia

2298. Dolný, A.; Volná, K.; Veselý, M. (2000): On the occurrence of dragonflies (Odonata) in two nature reserves of south-east Asia (Thailand, Malaysia). In: Hanel, L. (Ed.): *Vazky 2000. Sborník referátu III. celostátního semináře odonatologu, který se konal v Chráněné krajinné oblasti Trebonsko 15.-18.6.2000.* Vlasim. ISBN 80-86327-12-4: 171-174. (in Czech with English summary). [24 taxa are listed for Chiang Mai (Thailand) and Kenong Rimba State Park (Malaysia).] Address: Dolný, A., Katedra biologie e ekologie, Přírodovědecká fakulta Ostravské university, Bráfova 7, CZ-70103 Ostrava 1, Czech Republic.

2299. Dunkle, S.W. (2000): *Dragonflies through binoculars.* Oxford University Press. ISBN 0-19-511268-7: 266 pp, 47 plates. (in English). [I hesitate to write that it will be possible to identify with certainty a specimen using a binocular and using this book. To do so, (1) a lot of "plate-turing" will be necessary, and (2) stamp-scaled photos will not enable you in every case to identify the species. I think the blatant title of the book - I expected figures and photos definitively enabling the secure identification of a specimen - "dazes" the real quality of Sid Dunkle's book. It contains a lot of sound information on North American Anisoptera well organised in app. 15 introductory chapters and 307 species accounts. After careful reading, Sid's description of the very species will enable you in fact to identify a specimen: extensive information on identification, body features, and similar species provide a lot of help from one of the leading odonatologist, if not the authority on identification of North American Odonata. But, in field and using a binocular: is there enough to read the text and to find the plate with the very species? I feel not competent to assess this book resp. its didactical concept. Therefore I would recommend to read the reviews of Ken Tennessen in *Argia* 12(3), or Colin Jones in *Ontario Odonata* Vol 2. (Martin Schorr)]

2300. Fischer, S. (2000): Kleiner Beitrag zur Ernährung des Drosselrohrsängers *Acrocephalus arundinaceus*. *Berliner ornithologische Berichte* 10: 49-51. (in German with English summary). [Odonata regularly are a preferred prey of the Great Reed Warbler, *A. arundinaceus* (Aves). In contrast to this, no Odonata could be found as prey at the Müggelsee, Berlin, Germany.] Address: Fischer, S., Anzengruberstr. 23, D-12043 Berlin, Germany

2301. Friess, T. (2000): Libellen (Odonata) und Wanzen (Heteroptera) aus dem Naturschutzgebiet "Gut

Walterskirchen" am Wörthersee. Carinthia (II) 190/110: 517-530. (in German with English summary). [14 odonate species. are listed from the "Walterskirchen" property, W of Krumpendorf, on the northern shore of Wörthersee, Carinthia, Austria. 4 of these are redlisted and their occurrence and biology are outlined in some detail.] Address: Friess, T., Inst. Zool., Univ. Graz, Universitätsplatz 2, A-8010 Graz, Österreich

2302. Gerhards, E. (2000): Der fliegende Tod (Gottfried von Wedig, Stilleben, 1639), Wallraf-Richartz-Museum, Köln. SWR-Schulfernsehen Schuljahr 1999/2000 (3): 22-23. (in German). [A still life with a fly (Diptera: Muscidae) is described and background information on diseases caused by flies in past centuries are outlined. A dragonfly is sitting on an apple situated in a bowl. The text of the paper is laid out using *Aeshna cyanea*, but no reference is made to Odonata. Probably dragonflies symbolise most best a "flying death".] Address: SWR Schulfernsehen, Hans-Bredow-Straße, D-76530 Baden, Germany

2303. Gerken, B.; Böttcher, H.; Leitfeld, D.; Lohr, M.; Dörfer, K.; Leushacke-Schneider, C. (2000): Beurteilung von Regenerationsmaßnahmen durch vegetationskundliche und faunistische Untersuchungen - Beispiele aus der Oberweserniederung. Angewandte Landschaftsökologie 37: 205-216. (in German with English summary). [Results of a project to restore floodplain dynamics in the alluvium of the river Weser, Germany are briefly outlined. A status quo analysis was realized in 1989, restoration measures started in 1993. Vegetation was mapped in detail, and its succession and dynamic in the floodplain channel are illustrated. 32 species of Odonata are compiled in a table. Prior to the measures, 14 (1989) and 12 (1993) species could be observed. Species number increased in 1994 to 20, and 23 - 25 in 1995-1999. Dominance and abundance of species pulsated depending on habitat diversity and dynamic of water regime and vegetation development. Special emphasize is given to Lestidae, and the dependence of the genus from reed vegetation. The results demonstrate that measures as well as natural factors (flood) modify species composition, and make it sometime difficult to assess the "success" of the measures in a political framework.] Address: Lohr, M., An der Kirche 22, D-37671 Hötter, Germany. E-mail: mlohr@fh-hoexter.de

2304. Gueffroy, D.; Lieckweg, T. (2000): Zur Odonatenfauna des Fintlandsmoores (Landkreis Ammerland). Dossera, Oldenburg 2000: 53-65. (in German with English summary). ["On 10 excursions during 1999 the dragonfly fauna of the Fintlandsmoor, Ammerland county, was surveyed. The main focus of the survey was on the southern dystrophic rewetted bog and the undisturbed section of the former raised bog, which is situated in the centre of the nature reserve. A total of 15 indigenous dragonfly species were found. With reference to former surveys performed in 1973-78 and 1986 an increasing eutrophication was clearly shown by the changes in species composition. Currently suggestions for land-use, which would help secure the presence of certain endangered species such as *Ceriatagrion tenellum*, *Aeshna subarctica*, and members of the genus *Leucorrhinia*, are being developed and strengthened in order to protect these species within this region. It is important to note, that through a spatial separation of functions the conflicts between species protection, tou-

rism, and natural succession will be reduced. The high dragonfly species diversity as well as the species composition are indicative of the extreme natural value of the Fintlandsmoor." (Authors)] Address: Gueffroy, D., Littenweilerstr. 36c; D-79117 Freiburg, Germany. E-mail: gueffroy@uni-freiburg.de

2305. Halacka, K.; Hanel, L. (2000): Dragonflies (Odonata) of the alluvial area of the lower stream of the river Dyje (Southern Moravia, Czech Republic). In: Hanel, L. (Ed.): Vazky 2000. Sborník referátu III. celostátního semináře odonatologu, který se konal v Chránené krajinné oblasti Trebonsko 15.-18.6.2000. Vlasim. ISBN 80-86327-12-4: 118-129. (in Czech with English summary). [An intensive study from 1997 to 1999 along 32 stretches of the river Dyje, resulted in a total of 32 odonate species. Remarkable species are, *Lestes virens*, *L. dryas*, *Ischnura pumilio*, *Aeshna affinis*, *Anaciaeschna isocetes*, *Anax parthenope*, *Gomphus vulgatissimus*, *Orthetrum albistylum*, *O. brunneum*, *Sympetrum danae*, and *S. meridionale*.] Address: Hanel, L., Správa chránené krajinné oblasti Blaník, 257 06 Lounovice pod Blaníkem 8, Czech Republic. 2312. Kroehling, A. (2000): Renaturierung der Ergoldinger Au - Vorstellung der bisherigen Umsetzung (1995-1999). Selbstverlag Markt Ergolding: 26 pp. (in German). [Report of the realisation of an ambitious action plan for revitalising the floodplain of the Ergoldinger Au in Bavaria, Germany. Starting in 1991, in the successive period conservation and developing measures were realised. The report presents the results and the efficiency of measures for the period between 1995 and 1999. Odonata are referred and presented as "umbrella-species" or used as examples in the framework of environmental education. The booklet is a didactically very interesting combination of landscape or measurement plans with colour photos of species and habitats, and some general, but very interesting biological information. It can be ordered for 4 Euro at the address below.] Address: Markt Ergolding, Lindenstr. 25, D-84030 Ergolding, Bayern

2313. Lindenia No. 32 (2000): LINDENIA. Notiziario dell'Ufficio nazionale italiano della Società odonatologica internazionale, Napoli. Lindenia No. 32: 135-138. (in Italian). [Announcements of odonatological symposia; Dragonflies in WWW; Anax (Hemianax) ephippiger sightings in Italy, 1998- 2000] Address: C. D'Antonio, Via A. Falcone 386/b, 1-80127 Napoli, Italy; E-mail: lindenia@freemail.it

2314. Meier, C.; Zucchi, H. (2000): Zur Bedeutung von Regenwasserrückhaltebecken für Libellen (Odonata): ein Beitrag zum urbanen Artenschutz. Osnabrück. naturw. Mitt. 26: 153-166. (in German with English summary). [The investigations were carried out at 5 selected rainwater retention basins in the city of Osnabrück, Lower Saxony, Germany, where 22 out of the 27 regional species were evidenced. Though most of these were generalists, the results indicate the importance of city retention basins for the preservation of the fauna.] Address: Meier, C., Girardetstr. 71, D-45131 Essen, Germany.

2315. Mermet, E.; Galli, P. (2000): Contributo alla conoscenza delle libellule (Insecta: Odonata) del Varesotto. Bollettino della società di scienze naturali 88(1-2): 19-23. (in Italian with English summary) [Records of 47 species are documented and commented.] Address: Mermet, E., Civico Museo Insubrico di Storia Naturale, Piazza Giovanni XXIII, I-21056 Induno Olona, Italy.

2316. Mitchell, F.L.; Lasswell, J.L. (2000): Digital dragonflies. American Entomologist 46(2): 110-115. (in English). [The authors present a method conserving the colours of collected specimens. Odonata were refrigerated for app. 30 min, and put on a scanner. Catching dragonflies, handling, hard- and software are described in detail to realise optimal results of colour preservation. This interesting method is a combination of a conservative collection with dried pinned or acetoned specimens and a data base with identical scanned specimens.] Address: Lasswell, J.L., Institution Texas Agric. Exp. Stn., Route 2 Box 00, Stephenville, TX 76401, USA.

2317. Müller, Z.; Szállassy, N.; Jakab, T.; Bárdosi, E. (2000): Faunistical data on dragonflies (Odonata) from the ancient floodplain area Berek-lapos (Sárospatak). Studia odonatol. hung. 6: 55-68. (in Hungarian with English summary). [The paper presents faunistical data on dragonflies collected in the ancient floodplain area Berek-lapos, situated in the geographical microregion Bodrogbz (administrative area of the settlement Sárospatak), Hungaria. The fieldwork was carried out in 1999 at 12 localities. The list of 33 odonate species include the rare Hungarian Sympetrum danae as well as Brachytron pratense, Aeshna viridis, Epithea bimaculata, and Leucorrhinia caudalis.] Address: Müller, Z., Department of Ecology, Kossuth L. University, H-4010 Debrecen, P.O. Box 71, Hungary

2318. O'Brien, M. (2000): Williamson dragonfly gun confiscated! Argia 13(1): 22. (in English). [Verbatim: "In early February, Univ. of Michigan Dept. of Public Safety and Security conducted an inventory of firearms being stored in the Museum of Zoology While most of the attention was on the Bird, Mammal and Herpetology Divisions, it turned out that the only illegal weapon being stored here was in the Insect Division. Yes, you guessed it - the 22-cal. pistol with a soldered on 26" barrel that E.B. Williamson used to shoot down high-flying Odonata. He used 22 - cal. dust-shot rounds, which we-

re only potent enough to bag small creatures. I suspect that E.B. subscribed to "walking softly and carrying a big stick" and certainly the weapon in question looks somewhat impressive. Officer Tim Shannon was very apologetic about confiscating the pistol, as it was illegally modified under State law and also illegal under campus policy. However, since the weapon has not been fired in probably 75 years, it will not be a loss in terms of its use. At my suggestion, they'll make the pistol inoperable and return it so we can mount it on a plaque for display. Okay, so you thought dragonflies were harmless. They used to be bigger and a lot meaner, which was why EBW carried the weapon in the field. I don't know if they ever used dynamite for catching larvae." Address: O'Brien, M., Insect Division, Museum of Zoology, University of Michigan, Ann Arbor, MI 48109-1079, USA. E-mail: mfobrien@umich.edu

2319. Rus, I. (2000): The current state of knowledge about dragonflies (Odonata) research in the vicinity of the town Kolin near Labe river (Central Bohemia). In: Hanel, L. (Ed.): Vazky 2000. Sborník referátu III. celostátního semináře odonatologu, který se konal v Chráněné krajinné oblasti Trebonsko 15.-18.6.2000. Vlasim. ISBN 80-86327-12-4: 95-101. (in Czech with English summary). [1995-2000, 12 localities were surveyed for their Odonata. A total of 29 species also includes *Lestes virens*, *Sympetma fusca*, *Coenagrion pulchellum*, *Erythromma najas*, *Brachytron pratense*, *Crocothemis erythraea*, and *Sympetrum flaveolum*.] Address: Rus, I., Regionální muzeum, v Kolíne, Brandlova 27, CZ-28002 Kolin I, Czech Republic

2320. Schulz, C.-J.; Bellstedt, R. (2000): Die Wipper: Verödung und Wiederbesiedlung eines Flusses im ehemaligen Kalirevier "Südharz", dargestellt am Beispiel aquatischer Insekten. Abh. Ber. Nat. Gotha 21: 103-110. (in German). [The decline of potassium mining in Northern Thuringia, Germany led to a decrease in salinity of the river Wipper during the last years. Recolonisation of the river is documented comparing macrobenthos collections from the tenth, fifties, and ninties of the 20th century. Five odonate taxa including *Calopteryx splendens*, *C.virgo*, *Ischnura elegans*, and *Platycnemis pennipes*.] Address: Schulz, C.-J., Staatliches Umweltamt Sondershausen, Am Petersenschacht 3, D-99701 Sondershausen, Germany

2321. Wang, L.-J. (2000): Dragonflies of Taiwan. ISBN 957-30885-1-7: 349 pp. (in Chinese and English). [This is my favourite dragonfly book of the year. Liang-Jong Wang has written a fascinating book on the Taiwanese Odonata! The chapters and species accounts are written in Chinese. But to enable access to the species monographs, a brief "Natural history" and information on the distribution on the Asian scale are added. Together with the excellent, in some cases outstanding photographs of the species, you will have full access to the Odonata of Taiwan. Additional information is given - and sometimes illustrated by photographs - to morphology, life history, and behaviour. Very useful is the chapter of typical Taiwanese habitats: Photographs - reduced in scale - of the typical species of paddy fields, fish ponds, forest lakes and swamps, ponds in parks, mountain lakes, hill streams, and forest brooks are compiled and crossreferenced to the species chapter. This book definetly should not be missing in any odonatalogical library. (Martin Schorr)] Address: www.jccalendar.com.tw

2322. Wedmann, S. (2000): Die Insekten der oberoligozänen Fossilagerstätte Enspel (Westerwald, Deutschland). Systematik, Biostratonomie und Paläökologie. Mainzer Naturwissenschaftliches Archiv, Beiheft 23: 142 pp, Anhang. (in German with English summary). [The insect taphocoenosis from the Upper Oligocene lacustrine deposits of Enspel (Westerwald, Rheinland-Pfalz, Germany) was studied in detail. The systematic composition of the over 5000 insect fossils permits detailed paleoecological conclusions. These interpretations are based on the spectra of the different digging sites and horizons as well as on the ecological needs of the closely related extant taxa. The taphocoenosis is dominated by terrestrial insects. Aquatic taxa - including 15 specimens of Odonata - are represented with only a few fossils. *Oligaeschna jungi* is a dragonfly which is already known from a fossil site in France. Additional species are identified on the family-level. A zygopteran species is pictured on a colour plate showing the colouration of the species. The ecosystem of lake Enspel is reconstructed; Odonata are treated in some detail. The fauna of Enspel is compared with some other regional fossil deposits.] Address: Wedemann, Sonja, Institut für Zoologie und Anthropologie, Berliner Str. 28, D-37073 Göttingen, Germany. E-mail: swedman@gwdg.de

2323. Westermann, K. (2000): Die Eiablageplätze der Weidenjungfer (*Chalcolestes viridis*) in einem südbadischen Altrheingebiet. Naturschutz südl. Oberrhein 3(1): 93-107. (in German with English summary). [A survey for *C. viridis* clutches was conducted along the Old-Rhine nr Weisweil, co. Emmendingen, Baden-Württemberg, SW Germany. 37 tree and bush species with successfully hatched prolarvae were identified, 15 of them have not been previously mentioned in the literature. Young trees and bushes, such as *Viburnum opulus*, *Alnus glutinosa*, *A. incana*, *Fraxinus excelsior*, *Ligustrum vulgare*, *Salix alba*, some smaller willow species and *Prunus padus*, appear the preferred oviposition sites. The branches were selected from close above the water to an approx. height of 25 m, the number of clutches decreasing with the height. At some distance from the water, they were rarely seen.] Address: Westermann, K., Buchenweg 2, D-79365 Rheinhausen, Germany

2324. Yokoi, N. (2000): A list of dragonflies collected in Central Laos. Gekkan-Mushi 356: 18-22. (in Japanese with English summary). [23 species are dealt with, 20 of them are recorded for the first time in central Laos. *Prodasineura auricolor* (Fraser 1927), *Protosticta taipokauensis* Asahina & Dudgeon 1987, *Ictinogomphus pertinax* (Hagen 1854), *Labrogomphus torvus* Needham 1931, *Merogomphus paviei* Martin 1904, *E-pophthalmia elegans* (Brauer, 1865), *Macromia callisto* Laidlaw 1922, *Macromia chaiyaphumensis* Hämäläinen 1985, *Macromia pinratani* Asahina 1983, and *Hylaeothemis clementia* Ris 1909 are illustrated. *P. taipokauensis* and *E. elegans* are first records for Indochina. *I. pertinax* and *P. taipokauensis* are compared with specimens from Hong Kong, China.] Address: Yokoi, N., 2-37-11, Kaisei, Koriyama, Fukushima, 963-8851, Japan

2001

- 2325.** Abbott, J.C. (2001): Distribution of dragonflies and damselflies (Odonata) in Texas. *Trans. Am. Entomol. Soc.* 127(2): 189-228. (in English). [“205 species of Odonata are listed from Texas. County records, seasonal occurrence and habitat preference are given for each species. Publications containing Texas records are presented and briefly discussed in a history of the Odonata research in the state. The physiography of Odonata habitats and zoogeography of the species themselves are discussed. Texas contains a highly diverse odonate fauna, because of its unique geographic position and highly variable physical composition relative to other physiographic provinces. A total of 5,098 records of Odonata are documented from 210 counties in Texas. These records include personal collections, valid literature records, verified material in museum and personal collections, and verified photographic records.” (Author)] Address: Abbott, J.C., Univ Texas, Sect. Integrat. Biol., Austin, TX 78712 USA
- 2326.** Adena, J.; Handke, K. (2001): Die Libellenfauna von Grünland-Grabensystemen im Bremer Raum. *Bremer Beiträge für Naturkunde und Naturschutz* 5: 91-103. (in German with English summary). [Based on investigations starting in 1980, a compilation of the dragonfly fauna of 7 selected ditch systems in the lowlands of the Bremen area, Germany, is presented and analyzed. A total of 35 odonate species including 29 probably or securely indigenous species could be recorded. The species are discussed according their regional rarity, which discriminates the regions from other western or central European regions. Species like *Lestes sponsa*, *Coenagrion pulchellum*, *Aeshna grandis*, and *Sympetrum vulgatum* belong to the most common Odonata whereas species like *Enallagma cyathigerum*, *Aeshna cyanea*, and *Sympetrum flaveolum* are more rare ones. The rare *Brachytron pratense*, *Aeshna viridis*, and *Anaciaeschna isosceles* build strong populations in the ditch systems in the environs of Bremen. Factors as ditch maintenance, waterflow, water supply, water level, morphology, and vegetation succession explain different odonate coenoses and habitat quality for dragonflies. The most significant threat for the odonate coenoses of the ditch systems are high frequent dredging, upsilting and build over with buildings.] Address: Adena, Julia, Geibelstr. 61, D-28215 Bremen, Germany
- 2327.** Andrew, R.J.; Chandrasekhar, S. (2001): A collection of Odonata from Umrer, Nagpur district, central India, with a note on the behaviour of *Pantala flavescens* (Fabricius) in the rain. *Notul. odonatol.* 5(8): 97-108. (in English). [48 species are recorded, 5 of these are new to the fauna of central India. The behaviour of *P. flavescens* during rainfall is discussed in terms of endothermic warming. Feeding behaviour of *P. flavescens* on termites is shortly outlined.] Address: Andrew, R.J., Department of Zoology, Shri Shivaji ESA's Science College, Congress Nagar, Nagpur - 440012 (MS), India
- 2328.** Andrews, S.J. (2001): Some observations on the identification of the exuviae of the final-instar larvae of the Common Blue Damselfly *Enallagma cyathigerum* (Charpentier). *J. Br. Dragonfly Society* 17(2): 35-44. (in English). [A total of 553 exuviae of *E. cyathigerum* were collected: “Conclusions: Significant intraspecific variation in labial setation was noted and, as such, it is not considered a sufficiently consistent character to use for larval identification. It is suggested that the following amendments should be made to the commonly used specific characters to identify the exuviae of *E. cyathigerum*: (1.) Mean body length (including lamellae) about 20.5 mm (range 17 to 23.5 mm). (2.) Labial palp with a very small spine on at least one of the outer margins adjacent to the distal seta. (3.) Prominent mid-dorsal, longitudinal pale line on all visible segments except S10. (4.) Caudal lamella subnodate and about 6 mm long (range 3.5 to 7 mm), usually with one to three (rarely zero or four) narrow, transverse, dark bands; thicker setae generally reaching to (or beyond) the mid-point on both margins of the caudal lamellae.” (Author)] Address: Andrews, S.J., 39 Guildford Street, Staines, Middlesex TW18 2EQ, UK
- 2329.** Andretzke, H. (2001): Naturschutzmassnahmen am Grabensystem des NSG "Borgfelder Wümmewiesen" - Erfolgskontrolle anhand der Libellenfauna. *Bremer Beiträge für Naturkunde und Naturschutz* 5: 189-196. (in German with English summary). [The efficiency of reshaping measures at stretches of the ditch system in the nature protection area "Borgfelder Wümmewiesen" is assessed using Odonata. 26, including 19 indigenous species had been observed in the area. As to expect, the more ubiquitous species could be listed completely, but the target species of oxbow lakes and fens are still lacking about 4 years after first reshaping measures. But, even successful reproduction of the more common species was missed at most of the ditches with compensation measures due to unsuitable habitat conditions (e.g. extensive mudbeds). The author concludes that for the time the measures at the draining ditches have to be assessed as unsuccessful.] Address: Andretzke, H., BIOS, Lindenstr. 40, D-27111 Osterholz-Scharmbeck, Germany
- 2330.** Aoki, T. (2001): Active flights of *Chlorogomphus brunneus costalis* in late evening. *Sympetrum Hyogo* 7/8: 70. (in Japanese with English summary). [“Active flight of many males of *C. brunneus costalis* was observed in the evening during 17:30-18:50 on June 24, 2000 at Hiwasa-cho, Tokushima Prefecture, Japan. They flew low about 1 m above ground. In early hours most males came out of the shaded stream, where females oviposited in the morning, and went away along the road (path 1) and a few males returned to the stream (path 2). In later hours most males came out and went back soon to the shaded stream (path 2). When two males encountered on the road, one chased the other. Exceptions are a female flew from the opposite side (path 3) and a male staying for feeding at a space among the trees on the road side at 3 m above ground (path 5).” (Author) Path numbers refer to a figure with a map of the locality.] Address: Aoki, T., Rokko Island High School, Naka 4-chome, Koyo-cho, Higashinada-ku, Kobe, 658-0032, Japan. E-mail: taoki@ma3.justnet.ne.jp
- 2331.** Aoki, T. (2001): Odonata fauna of Kobe City, Part 9. (Corduliidae and supplement 2). *Sympetrum Hyogo* 7/8: 6-8. (in Japanese with English summary). [*Macromia amphigena* Selys 1871, *M. daimoji* Okumura, 1949, *Epophthalmia elegans* (Brauer, 1865), *Soma-tochlora viridiaenea* (Uhler 1858), *S. clavata* Oguma 1922, *S. uchidai* Förster 1909, *Epiteca marginata* (Selys 1883), *Sympetrum uniforme* (Selys 1883), *Lanthus fujiacus* (Fraser 1936), *Tramea virginia* (Rambur 1842), *Tanypteryx pryeri* (Selys, 1889), *Cercion melanotum*

(Selys, 1876), and *Ceriagrion nipponicum* Asahina 1967 are treated in the 9th part of the odonata fauna of the city of Kobe, Japan.] Address: Aoki, T., Rokko Island High School, Naka 4-chome, Koyo-cho, Higashinada-ku, Kobe, 658-0032, Japan. E-mail: taoki@ma3.justnet.ne.jp

2332. Aoki, T. (2001): Three males of *Sympetrum depressiusculum* were caught in Ibogawa-cho, Hyogo Prefecture. *Sympetrum Hyogo* 7/8: 13. (in Japanese with English summary). [S. *depressiusculum* was found on October 22, 2000 at a pond in Baba, Ibogawa-cho, Hyogo Prefecture, Japan. This record is one of the scarce records on the Setonaikai Inland Sea side, while in contrast more records on the Japan Sea side are made. The pond was visited again on November 3, but the species had disappeared.] Address: Aoki, T., Rokko Island High School, Naka 4-chome, Koyo-cho, Higashinada-ku, Kobe, 658-0032, Japan. 2333. Auerswald, J.; Franke, T.; Reisinger, E. (2001): Erfolgreiche Pflegemaßnahmen im NSG "Dreba-Plöthner Teichgebiet". *Landschaftspflege und Naturschutz in Thüringen* 38(2): 62-65. (in German). [Efficiency of conservation measures in the Nature Conservation Area "Dreba-Plöthener Teichgebiet" (Thüringen, Germany) was assessed using some indicator species. Odonata are mentioned to have developed strong populations, and the species mentioned are including e.g. *Anaciaeschna isosceles*.] Address: Auerswald, J., Landratsamt Saale-Orla-Kreis, Umweltamt, Oschitzer Str. 4, D-07907 Schleiz, Germany

2334. Azuma, T. (2001): Distribution of *Trigomphus melampus* in Hyogo Prefecture. *Sympetrum Hyogo* 7/8: 4-5. (in Japanese with English summary). [18 new habitats of *T. melampus* were discovered in the northern district of Hyogo Prefecture, Japan, in 1999, totaling the known habitats to 24. Larvae prefer shallow ponds with grass vegetation; it is assumed that they inhabit irrigation ditches too. The distribution of the species is limited to the northeastern parts, namely Kinosaki-gun, Toyo-oka City and Mikata-gun, and does not reach Yabu-gun. Abandonment of traditional rice field cultivation and development of artificial irrigation ditches are reasons for regressing populations of this species.] Address: not stated

2335. Azuma, T. (2001): Odonate fauna of Sanda City, Gyogo Prefecture. *Sympetrum Hyogo* 7/8: 14-20. (in Japanese with English summary). ["The odonate fauna of Sanda City, Hyogo Prefecture, Japan, had been reported only incompletely, while the urbanization owing to an exceptional rapid expansion of population has caused big loss of natural environment. [...] To document the remaining odonate fauna, 90 localities had been surveyed in 1998. Now, 61 species including the author's unpublished former records of 1972 and 1993 are known from the region. Sogame (1998, 1999) recorded additional 13 species; this totals the number of species to 74.] Address: not stated

2336. Baumann, K. (2001): Habitat und Vergesellschaftung von *Somatochlora alpestris* und *S. arctica* im Nationalpark Harz (Odonata: Corduliidae). *Libellula* 20 (1/2): 47-67. (in German with English summary). ["In 2000, thirty moorland pools and the pothole in the "Odersprungmoor" have been analysed in regard to their population of dragonflies by collecting exuviae. In the

moorland-pools different data concerning the structure were surveyed in order to compare the habitat selection of the various species. In total, 705 exuviae of 10 species were collected. The species with the highest number of individuals was *Leucorrhinia dubia*. *Somatochlora alpestris* was detected in most of the pools but the populations usually were small. This species and the less frequent *S. arctica* could be found in the smallest and shallowest waterbodies. Both were able to coexist with up to 5 additional species. Larger populations of both *Somatochlora* species and *Leucorrhinia dubia* excluded each other." (Author)] Address: Baumann, Kathrin, Arbeitsgemeinschaft für Landschaftsplanung, Naturschutz und Umweltstudien (ALNUS GbR), Rudolf-Huch-Straße 6, D-38667 Bad Harzburg, Germany. E-Mail: alnus-k.baumann@t-online.de

2337. Bechly, G.; Brauckmann, C.; Zessin, W.; Gröning, E. (2001): New results concerning the morphology of the most ancient dragonflies (Insecta: Odonoptera) from the Namurian of Hagen-Vorhalle (Germany). *J. Zool. Syst. Evol. Res.* 39(4): 209-226. (in English). ["The holotype specimen of the 'protodonate' *Erasipteroides valentini* (Brauckmann in Brauckmann et al., 1985) and the paratype specimen K-13 of the giant 'protodonate' *Namurotypus sippeli* Brauckmann and Zessin, 1989 from the Upper Carboniferous (Namurian B) of Hagen-Vorhalle (Germany) are redescribed, and a new specimen of *Erasipteroides* cf. *valentini* is described. The new evidence is used to refine the groundplan reconstruction of Odonoptera and the reconstruction of odonatoid phylogeny. Prothoracic winglets for *Erasipteroides* and the absence of an archaedictyon are documented. Furthermore, a very long and sclerotized ovipositor with gonangulum is described from the female holotype specimen of *Erasipteroides valentini*, and it is proposed that it was not used for endophytic but for endosubstratic oviposition. The record of prothoracic winglets in early 'odonatoids' and their presence in fossil Palaeodictyoptera and 'protorthopteres', indicates that the groundplan of Pterygota indeed included three pairs of wings. A phylogenetic analysis suggests that the Palaeozoic giant Meganisoptera and "higher" odonatoids (incl. crown group Odonata) together form a monophyletic group which is here named Euodonoptera. *Erasipteroides* and the other 'Erasipteridae' are shown to be more closely related to Euodonoptera than to Eugeopteridae. The description of the male primary genital structures of *Namurotypus sippeli* is emended and a new interpretation is proposed including new hypotheses concerning their function. The males of *Namurotypus* had a paired penis with a pair of lateral parameres, and a pair of leaf-like, but still segmented, gonopods. Segmented leg-like male gonopods are considered as a groundplan character of insects, while a paired penis is regarded as a putative synapomorphy of the palaeopterous insect orders Palaeodictyopteroidea, Ephemeroptera, and Odonoptera. It is proposed that *Namurotypus* did not mate by direct copulation but retained the archaic deposition of external spermatophores, just like the primarily wingless insects. The sigmoidal male cerci may have been placed behind the female head and used to drag the female over the spermatophore, which is remotely similar to the mating behaviour of some extant arachnids (e.g. *Amblypygi*). Three hypothetical scenarios regarding the evolution of secondary copulation in modern Odonata are proposed." (Authors)] Address: Bechly, G., Staatliches Museum für

Naturkunde, Abt. Paläontologie, Rosenstein 1, D-70191 Stuttgart, Germany. E-mail bechly@gmx.de

2338. Beckemeyer, R. (2001): Biological diversity and politics: the impact of recent regulatory trends on scientists who study the taxonomy and distribution of organisms. *Argia* 13(1): 28-29. (in English). [This is a discussion of current trends in getting collecting permissions in the framework of biodiversity politics. Current regulations in India and Brazil are to assess that they will stop any transboundary scientific work on species. "This is a sad state of affairs that truly bodes ill for increasing our understanding of Earth's biodiversity."] Address: Beckemeyer, R.J., 957 Perry, Wichita, KS 67203-3141, USA. [Some brief information is given on a book "Nature stories for little folk" from the beginning of the 20th century including some dragonfly illustrations and a story about a dragonfly.] Address: Belshe, J.F., 221 SW 21 Rd., Warrensburg MO 64093, USA

2344. Bender, J.; Xylander, W.E.R.; Stephan, R. (2001): Lösungsansätze im Zielkonflikt zwischen Rekultivierung und Naturschutz in der Bergbausanierung-Wiederherstellung eines Libellengewässers auf Halden des Braunkohletagebaus Berzdorf. Abh. Ber. Naturkundemus. Görlitz 73(1): 3-8. (in German with English summary). ["A geological depression was formed by chance during mine dumping at the Neuberzdorfer Holz. In the course of natural events the depression developed into a favourable biotope for dragonflies, in which a number of rare species have been recorded. After the closing of mining activities in 1997 reclamation work began, which in the meanwhile has led to a nearly total destruction of the new biotope. It was agreed between the mining corporation, the conservation authorities and the Natural History Museum in Görlitz to create a similar biotope in the vicinity as a replacement for that lost through reclamation activities." (Authors) Habitat developing measures with special emphasize to Odonata are outlined.] Address: Xylander, Dr. W., Staatliches Museum für Naturkunde Görlitz, PF 300154, D-02806 Görlitz, Germany. E-mail: Naturmuseum. GR.Dr. Xylander@t-online.de

2345. Benedikt R. Schmidt, B.R.; Van Buskirk, J. (2001): Verhalten, Wachstum und Morphologie von Kammolch-Larven in der An- und Abwesenheit von Libellenlarven. *Rana*, Sonderheft 4: 179-191. (in German with English summary). ["We tested for predator-induced plasticity in behavioural, morphological and life-history traits of larvae of the newt *Triturus cristatus* using larvae of the dragonfly *Aeshna cyanea* as predators. There was no evidence for plasticity in morphology or life history in a controlled experiment and we found no evidence for morphological plasticity in samples taken from natural ponds. In contrast to other newt species, larvae of *T. cristatus* were more active in the presence of predatory dragonflies. We do not know why phenotypic plasticity in *T. cristatus* is different from the predator-induced defences seen in other newt species. We suggest that differences between newt species in plasticity and predator-prey interactions may affect their distribution and abundance." (Authors)] Address: Buskirk, J. van, Institute of Zoology, University of Zürich, CH-8057 Zürich, Switzerland. E-mail: jvb@zool.unizh.ch; bschmidt@zool.inizh.ch

["In an article in the journal "Körkmacken" (No. 27, August 2000, pp. 14-15) of the Gotland Entomological Society, Werner and Gudrun Burkart briefly presents their records of *Symplocma fusca* and *S. paedisca* in April 2000 at the island Gotland in the Baltic sea. Both species are new to Gotland, and the record of *S. paedisca* is the first for Sweden and Scandinavia."] Address: Burkart, W. a. G., Am Emel 7, D-27412 Wilstedt, Germany

2359. Burks, R.L.; Jeppesen, E.; Lodge, D.M. (2001): Pelagic prey and benthic predators: impact of odonate predation on *Daphnia*. *J. N. Am. Benthol. Soc.* 20(4): 615-628. (in English). ["Interactions between benthic predators and pelagic prey, such as larval odonates and *Daphnia*, are often used to describe classic predator-prey relationships in laboratory-studies. However, few field studies explore the potential impact of benthic predators on pelagic prey. Recent studies of cladocerans document diel horizontal migration (DHM), where large-bodied zooplankton (i.e., *Daphnia*) decrease their exposure to pelagic predators by seeking refuge among macrophytes. However, daphnids undergoing DHM may simultaneously increase their likelihood of encountering benthic predators that commonly occur in littoral zones. In laboratory experiments, we showed that dragonfly nymphs (*Epiheca cynosura*) effectively eliminated all *Daphnia* within 24 h, regardless of macrophyte presence or architecture. We also tested whether additions of larval damselflies (*Ischnura elegans*, *Coenagrion puella*, *C. pulchellum*) and dragonflies (*Somatochlora flavomaculata*) (total odonate density of 35-55 / m²) significantly reduced total zooplankton or benthic invertebrate abundance in field enclosures with different macrophyte densities (20, 40, 80% volume infested [PVI]). Odonates significantly reduced *Daphnia* abundance at 20 PVI. However, the magnitude of the influence of odonates on daphnids, as well as *Ceriodaphnia* and *Polyphemus*, decreased with increasing macrophyte density. Odonate predation did not significantly affect benthic taxa abundance. Thus, daphnids undergoing DHM may lower predation from pelagic predators, but our results suggest that mortality from littoral predators may be significant. The net benefit of DHM may, therefore, differ among lakes as a function of the relative threats posed by pelagic and littoral predators." Metcalf, Ontario K0A 2P0, USA. E-mail: brownell@achilles.net

2371. Catling, P.M. (2001): Streams and rivers highlighted as major natural area protection priorities in Ontario based on damselfly and dragonfly indicators. In: Catling, P.M., C.D. Jones & P. Pratt (Eds): Ontario Odonata, vol. 2. Toronto Entomologist's Association, Toronto, Ontario: 36-43. (in English). ["The highest ranking groups of Ontario Odonata of conservation concern include globally vulnerable (G3) and provincially critically imperilled (SI) species most of which are inhabitants of large rivers and streams. In fact there are significantly more rare species in high risk categories associated with rivers and streams than would be expected on the basis of habitat frequencies of Ontario Odonata overall. Particular Ontario rivers highlighted for biodiversity protection on the basis of Odonata are the Ausable, Ottawa, Sydenham, and Thames, and these same rivers have been highlighted by other groups of environmental indicators such as Unionid molluscs. Recent emphasis on the protection of wetlands has focussed on extensive areas with emergent plant communities, while rivers and streams have suffered seriously inadequate attention." (Author)] Address: Catling, P.M., 2326 Scrivens Drive, R.R. 3, Metcalfe, Ontario K0A 2P0, USA. E-mail: brownell@achilles.net

2372. Chovanec, A.; Waringer, J. (2001): Ecological integrity of river-floodplain systems-assessment by dragonfly surveys (Insecta: Odonata). Regul. Rivers: Res. Manage. 17(4-5): 493-507. ["Dragonflies are reliable indicators of the ecological quality of land-water ecotones, habitat heterogeneity and the hydrological dynamics of water bodies. In recent years, surveys of dragonfly communities have become a powerful tool for the ecological assessment of floodplain areas. The goal of this paper is to present a new approach towards assessing the ecological integrity of river-floodplain systems by analysing resident breeding dragonfly species. The methodology is based on experiences with existing approaches using macroinvertebrates as bioindicators, in particular, calculations of saprobic indices, longitudinal zonation and functional feeding group patterns. In addition to the total number of species and the number of sensitive species, the 'Odonate Habitat Index' (OHI) is a key element of the assessment method. It indicates characteristic features of a river-floodplain system, such as connectivity aspects, flow dynamics and terrestrialization processes. The OHI is calculated from the species-specific habitat values (expressing habitat preferences), abundances and the species-specific indication weight, which distinguishes eurytopic from stenotopic species. The comparison of the status quo with a reference condition allows an assessment of individual water bodies and/or of a whole area in a five-tiered classification scheme. The approach presented may also be used for the evaluation of restoration measures (e.g. reconnection of side arms) and for the definition of management objectives. Apart from the methodological framework, the results of a first application of this approach are presented in the paper as well. The study areas were selected floodplain systems of the Austrian section of the Danube and man-made inshore structures of the impounded Danube section in Vienna." 2375. Cook, T.J.P.; Janovy, J.; Clopton, R.E. (2001): Epimerite-host epithelium relationships among eugregarines parasitizing the damselflies *Enallagma civile* and *Ischnura verticalis*. J. Parasitol. 87(5): 988-996. (in English). ["The host-parasite interface between 2 species of damselflies and 4 species of eugregarines was examined at the ultrastructural level. *Nubenocephalus nebraskensis* organisms attached to the host midgut epithelium by means of a sucker-like protomerite; the space between the epicytic folds and host epithelium was filled with electron-dense material interpreted to be adhesive in nature. *Actinocephalus carrilynae* organisms attached by means of the epimerite, which had no epicytic folds, and by the fluted stalk with characteristic epicytic folds; host cell and parasite membranes appeared fused at some places on the epimerite. *Hoplorhynchus acanthatholius* organisms attached by means of an ovoid epimerite with backward-pointing digitations; the entire epimerite was embedded in a host cell, and host cell microvilli surrounded the stalk. *Steganorhynchus dunwoodyi* organisms attached by means of an ovoid stalk papilla enclosed in a retractable globular sheath; the papilla was covered with epicytic folds, but the sheath was not, and the sheath had a single membrane, whereas the epicytic folds had 2 or 3 membranes. The entire apparatus was inserted between epithelial cells, and the sheath was highly folded at its surface. The ultrastructural observations suggest that actinocephalid gregarines have evolved 2 general strategies for attaching to the host epithelium, that is, suckerlike protomerites, as in the case of *N. nebraskensis*, and deeply embedded epimerites inserted within or between host cells, as in the other species studied." (Authors)] Address: Janovy, J., Univ Nebraska, Sch. Biol. Sci., Lincoln, NE 68588 USA

- 2377.** Curry, J.R. (2001): Dragonflies of Indiana. Indiana Academy of Sciences. ISBN 1-883362-11-3: 303 pp. (in English). [European readers may know Indiana from the mad rush of racing cars across the Indianapolis circuit. This wonderful book gives the chance to read something about fast flying beasts, the dragonflies. Dragonflies means Anisoptera, Zygoptera are not treated in the book. Curry's book starts with a brief but very readable account on a history of dragonfly biology in Indiana with some very prominent members of our community as T. Say, E.B. Willamson, and B.E. Montgomery. This chapter is followed by an account of the immature stages and life history. 97 individual species accounts, which comprise the bulk of the book, are clearly organised as follows: Most of the species in the book are represented by two photographs. These illustrate the recognition characters discussed in the text. The common names are heading each species chapter. Specific characters common or unique to the species including the mean size are listed to aid in identification ("Recognition"). "Indiana Flight season" data are based upon published reports as well as specimens in the collection of the author. "Status" indicate the current status of the species in Indiana. A "description" of the physical characteristics of the species intends to focus identification on essential morphological characters. In the paragraph "Habitat" it is outlined where the species is most commonly found to exist, including its preferred breeding habitat. Commonly observed habits ("Behaviour") may help in identification. North American "ranges" are based primarily upon published reports. A visual display of the flight season in Indiana, and distribution maps on the basis of counties where the particular species has been reported provide additional information. A glossar and a bibliography are also useful. From the European view, I personally think this is a wonderful book fascinating in its scope and in the quality of species (and habitat) photographs. I am very glad to have the book in my library. (Martin Schorr)] Address: Indiana Academy of Science, Chair of Publ. Comit., Bill N. 2394. Englund, R.A.; Polhemus, D.A. (2001): Evaluating the effects of introduced Rainbow Trout (*Oncorhynchus mykiss*) on native stream insects on Kauai Island, Hawaii; Contribution No. 2001-012 to the Hawaii Biological Survey, Bishop Museum. *Journal of Insect Conservation* 5(4): 265-281. (in English). ["Rainbow trout (*Oncorhynchus mykiss*) and other salmonids have been widely stocked into upland streams throughout the world to provide a basis for sport fisheries, but the effects of such introductions on indigenous and endemic aquatic insect assemblages are poorly documented. In this study, we examine the impact of rainbow trout on the indigenous and endemic entomofauna of upland streams in Kokee State Park, Kauai, Hawaii, with particular emphasis on the potential threat trout pose to populations of endemic damselflies in the genus *Megalagrion*. Rainbow trout were introduced into the upland streams of Kauai beginning in the 1920s, with over 60 years of subsequent restocking. This study indicates, however, that streams in this area still maintain diverse populations of *Megalagrion* damselflies and other indigenous and endemic aquatic insects, both in catchments containing naturally reproducing trout populations and in catchments lacking rainbow trout. Our results indicate that the indigenous and endemic aquatic insect communities in the streams under study compare favorably in terms of density and taxonomic richness with other isolated and unimpacted streams elsewhere in Hawaii, and retain high densities and relative percentages of indigenous and endemic aquatic insect taxa. Our results demonstrate that the threats posed by conspicuous introduced species such as trout should not simply be assumed a priori on the basis of postulated negative interactions, because this may divert limited resources from programs aimed at control of other, potentially more destructive introduced taxa such as inconspicuous poeciliid fishes." 2395. Fleck, G.; Nel, A.; Bechly, G.; Martinez-Delclos, X. (2001): Revision and phylogenetic affinities of the Jurassic Steleopteridae Handlirsch, 1906 (Odonata : Zygoptera). *Insect Syst. Evol.* 32(3): 285-305. (in English). ["The Jurassic odonate family Steleopteridae is revised. Two new genera and species *Parasteleopteron guischari* and *Euparasteleopteron vohli* are described. The phylogenetic affinities of this group are discussed. The Steleopteridae are excluded from the Epiproctophora and transferred into the Zygoptera (stemgroup). *Euphaeopsis multinervis* is redescribed and transferred to Epiproctophora: Isophlebioidea, and the genus *Pseudoeuphaea* with its four species is considered as a nomen dubium in Odonata incertae sedis." (Authors)] Address: Fleck, G., Lab. Ent., Mus. Natn. Hist. Nat., 45 rue Buffon, F-75005 Paris, France

2396. Fukui, M.; Iwamoto, A.; and 21 other members (Okegayanuma group of Biology Club of Iwata-minami Prefectural High School) (2001): A study of the way to breed *Libellula angelina* in the Okegayanuma, Iwata - city. *Nature and Insects* 36(7): 20-23. (in Japanese). [Introduction: Okegayanuma marsh is located at the northeast of Iwata-city, the west of Shizuoka Prefecture, and famous for the rich habitat of aquatic creatures, especially dragonflies. Among them, *L. angelina* is designated as Endangered species in RDB List. To protect the environment, local people, government and nature conservation groups are in action in closer connection. We investigated the population size since 1991. In 1993 to 1994 the population amounted 700 to 800 but thereafter it decreased and at last in 1999 only to 47. This was a critical situation. The factor of the sharp decrease was the burst multiplication of crayfish. We caught more than 20000 crayfish in the year, and from the year on we have continued to rid the marsh of it. 2. Breeding in our high school: Under the permission of the Ministry of the Environment we caught ten female of *L. angelina* in mid May, and got 5000 to 6000 eggs. We bred them in outdoor plastic containers, each containing aquatic plants, and bred 60 to 210 larvae in each container. At first we bred them with planktons which were collected from ponds, and brine shrimp and from the later stages with tubifexes and larvae of midge. 3. Result and analysis of the conditions of breeding: Larvae bred in 41 cases in 1999 to 2000 amounted 1326, and in 2000 to 2001, 1813 in 52 cases. The mean of larvae bred outdoors 36.9 for each case (total 49), and 1.3 indoors (3 cases). Larvae were bred outdoors more than indoors. This seems to be due to abundance with plankton, supply of rain water, and oxygen supply by water plants. The mean viability was 24.4%. 4. Emergence from bred larvae at Okegayanuma and its effect: Bred larvae (1300) were moved to the marsh, where emergence began on April 15, reached its peak on April 23. More than 70% of emergence from the larvae were counted. Adults of 131 were recorded. Adults came to oviposit in the containers for emergence. 5. Management of breeding containers and tracking of growth of larvae: We compared the conditions of larval growth between the containers from which intruders' larvae were eliminated and those not eliminated. Intruders were seven species; *Crocothemis servilia mariannae*, *Orthetrum albistylum speciosum*, *Lyriothemis pachygastra*, *Pantala flavescens*, *Anax parthenope julius*, *A. nigrofasciatus nigrofasciatus*, *Rhyothemis fuliginosa*. Among them *A. n. nigrofasciatus* has great impact to the larvae of *L. angelina*. Translation: Ishizawa, Naoya] Address: not stated

2397. Gaino, E.; Reborra, M. (2001): Apical antennal sensilla in nymphs of *Libellula depressa* (Odonata: Libellulidae). *Invertebr. Biol.* 120(2): 162-169. (in English). ["In an ultrastructural study of the apical antenna of the last nymphal stages of *Libellula depressa* (Odonata: Libellulidae), we found long sensilla trichodea, 2 sensory pegs, and a coeloconic sensillum on the last article of the flagellum (the distal part of the antenna). The long sensilla trichodea are mechanoreceptors, almost identical to the long filiform hairs of some terrestrial insects and the first sensilla of this kind to be described in aquatic insects. Particular attention was given to the complex coeloconic sensillum, a compound sensillum innervated by 2 groups of 3 neurons wrapped in a dendritic sheath. A cuticular sleeve envelops the distal portion of the outer dendritic segment. The cuticle of the coeloconic sensillum shows wide channels and is contiguous to the underlying granular and fibrillar layer. Similar structures on the antennae of the adults of other dragonflies were identified as chemoreceptors in previous studies. We hypothesize that this larval coeloconic sensillum might likewise have a chemosensory function, responding to molecules that diffuse through the cuticle and the underlying granular and fibrillar layer, as no clear pore or pore-tubule system is visible. Alternative functions are also explored on the basis of morphological details." (Authors)] Address: Gaino, E., Univ. Perugia, Dipartimento Biol. Anim. & Ecol., Via Elce Sotto, I-06123 Perugia, Italy

2402. Goretti, E.; Ceccagnoli, D.; La Porta, G.; Di Giovanni, M.V. (2001): Larval development of *Aeshna cyanea* (Müller, 1764) (Odonata: Aeshnidae) in Central Italy. *Hydrobiologia* 457: 149-154. (in English). ["A three-year investigation was carried out on the life cycle of *A. cyanea* in temporary freshwater pools in Central Italy. The instars were discriminated by size and scatter plot, based on measurements of labium length, head width, metafemur length, forewing-pad length and total larval body length. The prolarvae instar was derived by Dyar's law. The mean increase value index between following and previous instar was between 1.26 and 1.33 for isometric variables, and around 1.96 for the wing-pad allometric variable. *A. cyanea* entered diapause mainly at the F-2 instar, placing it almost intermediate between the Southern Spain populations, which usually overwintered in the F-3 instar, and those of England and Central Europe, who spent their last winter in F-1. *A. cyanea* appeared to be a 'summer species', as defined by Corbet (1962), and the population we studied had a semi-voltine life cycle." 2403. Grand, D.; Greff, N.; Delcourt, G. (2001): *Leucorrhinia pectoralis* (Charpentier, 1825) nouveau pour le département du Rhône. *Martinia* 17(3): 107-109. (in French with English summary). [In 2000, *L. pectoralis* was recorded at two localities of the Rhône département,

France. The habitats and co-occurring species are described.] Address: Grand, D., Impasse de la Voûte, F-69270 St. Romain-au-Mont d'or, France

2404. Grimaldi, D. (2001): Insect evolutionary history from Handlirsch to Hennig, and beyond. *J. Paleontol.* 75 (6): 1152-1160. (in English). ["Significant investigators and aspects in the past century of insect paleontology are briefly reviewed. Despite the pervasive influence of the paleontologist Willi Hennig in systematic biology, the study of fossil insects remains more descriptive than most other paleontological areas. Hypotheses are reviewed on relationships and chronologies of early divergences in insects (Paleozoic, Lower Mesozoic), particularly living and extinct orders of the lower pterygotes and putative monophyly of the Paleoptera (Odonata + Ephemeroptera). The Dictyoptera (Mantodea, Isoptera, Blattaria) illustrate relationships and discrepancies between stratigraphic record and phylogenetic relationships. Future directions in the field are suggested." (Author)] Address: Grimaldi, D., Amer. Museum Nat. Hist., Dept. Invertebrates, New York, NY 10024 USA

2405. Gubbels, R. (2001): Eerste waarneming van *Gomphus flavipes* (Charpentier, 1825) in België: een grensgeval. *Gomphus* 17(1): 3-8. (in Dutch with English and French summaries). ["First observation of *G. flavipes* in Belgium: a borderline case. In the summer of 2000 two males of *G. flavipes* were found along the river Meuse (Grensmaas) in the neighbourhood of Maasmechelen. This is the first observation of *G. flavipes* for Belgium." (Author)] Address: Gubbels, R., Langs de Veestraat 15, NI-6125 RN Obbicht, The Netherlands

2406. Günther, A. (2001): Differenzierung von Drohflügen und Balzverhalten verschiedener Rhinocypha-Formen Sulawesi (Indonesien). *Abh. Ber. Naturkundemus. Görlitz* 73(1): 25-26. (in German with English summary). ["The genus *Rhinocypha*, which has its distribution range in southeast Asia, exhibits ritualised threatening flights and specialised courtship behaviour, both of which are closely connected with the egg deposition substrate. The differentiation of this behaviour in several *Rhinocypha* species is briefly described and discussed." 2407. Guerold, F.; Boudot, J.-P.; Jacquemin, G. (2001): Première preuve de la reproduction d'*Aeshna affinis* Vander Linden, 1820 (Odonata, Anisoptera, Aeshnidae) et nouvelles observations d'Odonates rares en Lorraine. *Martinia* 17(3): 77-87. (in French with English summary). ["During Odonatological studies in the Lorraine area in 1999, we observed both immature and mature males of *Aeshna affinis* in the vicinity of Pont-à-Mousson. An exuvia corresponding to this species was collected on macrophytes growing in a artificial pond resulting from archaeological soundings. This observation constitutes the first evidence of the reproduction of *A. affinis* in the Lorraine region. Companion species and earlier records of this species in NE France are specified. Other records of rare or new species in this area (*Lestes barbarus*, *Coenagrion scitulum*, *Aeshna isoceles*, *Anax parthenope*, *Sympetrum meridionale*, *S. flaveolum*, *S. fonscolombii*, *S. pedemontanum*, *Leucorrhinia caudalis*, *L. pectoralis*) are brought on record. *Boyeria irene* was found one time at short distance of the

the Lorraine limits. Some of these dragonflies are thermophilous species often regarded in progression towards the N of Europe. Some of them were known in Lorraine in the second half of the 19th century, but have not been recorded again since." (Authors)] Address: Guerold, F., Université de Metz, Équipe d'Écotoxicologie, Campus de Bridoux, BP 4116, F- 57040 - Metz Cedex 1, France. E-mail: gue- rold@bridoux.sciences.univ-metz.fr

2408. Handke, K.; Adena, J. (2001): Zur Fauna neu angelegter Gewässer in der Bremer Flussmarsch unter besonderer Berücksichtigung der Libellen. Bremer Beiträge für Naturkunde und Naturschutz 5: 175-188. (in German with English summary). [In the middle of the 1980th in the Niedervieland-region near Bremen, Germany due to industrial development measures many habitats had been destroyed. To compensate habitat destruction, due to legal restrictions new habitats had to be created, and the success of the measures had to be monitored. In 1997 28 odonate species including 21 indigenous species colonised the newly created system of waters. The authors conclude, that "most of the animal species of the former ditch systems have also been found at and in the new waters in the course of the ten years." But compared to the old ditch systems significant differences turned out for the specialists of Water Aloe (*Stratiotes aloides*) habitats like *Aeshna viridis* and *Anaciaeschna isosceles*, which are less frequent than formerly. The paper provides some interesting observations on dispersal of species and on succession of odonate species composition in dependence of the succession status of the waters.] Address: Handke, K., Delmestr. 28, D-27777 Ganderkesee, Germany

2409. Hardersen, S. (2001): "Fluctuating Asymmetry" als Instrument für die Bioindikation mit Libellen. Abh. Ber. Naturkundemus. Görlitz 73(1): 27-28. (in German with English summary). ["The damselfly *Xanthocnemis zealandica* was used to investigate the practicability of 'fluctuating asymmetry' (FA) as a bioindicator. Exposure of the last larval instar to the insecticide carbaryl (40 ppb) increased the level of FA compared with the control in the laboratory. Attempts to confirm these laboratory results using artificial ponds or field populations were only partly successful. It is concluded that the use of FA as a bioindicator is fraught with difficulties." (Author)] Address: Hardersen, S., Tiergartenstr. 111, D-47533 Kleve, Germany. E-mail: sonke7hard@aol.com

2410. Harding, R.W. (2001): *Enallagma aspersum* in Prince Edward Island. *Argia* 13(2): 2-3. (in English). [First record of *E. aspersum* at Isaac's Lake, Prince Edward Island, Canada on 2 Sept. 2000.] Address: Harding, R.W., PR#3 Montague, Summerville, PE, C0A 1R0, Canada

2414. Heitz, S. (2001): Integration des Libellenschutzes in die Unterhaltung von Wiesenbächen. Maßnahmen zum Schutz der Helm-Azurjungfer (*Coenagrion mercuriale*) im Ortenaukreis (Baden-Württemberg). Diplomarbeit an Institut für Landschaftspflege und Naturschutz der Universität Hannover. 98 pp., Anhang. (in German). [Ditch management in most cases leads to significant impacts on fauna and flora. This thesis provides sound information and practicable measures to combine a ditch management that guarantees minimal (and where necessary, differentiated) economical and ecological standards. The partitioning of ditches into a system of stretches enables *C. mercuriale* (and additional species as *Orthetrum coerulescens* etc.) to complete its life cycle, to disperse, and to recolonize new stretches. This thesis can be considered a handbook for ditch management with special emphasize on Odonata. In addition it provides plenty of information referring to general aspects of ditch management, and it compiles the long lasting experience of conflict management between German conservationists and the responsible authorities for ditch management. The thesis is organized, so it even enables everyone from abroad and non German speaking persons to profit from the study. It is highly recommended to everybody interested in *C. mercuriale* or ditch management. (Martin Schorr)] Address: Heitz, S., Moosweg 15, D-77749 Hohberg, Germany

2415. Herren, B.; Herren, K. (2001): Libellule in Sicilia (Autunno 2000). *Lindenia* 34: 144-145. (in Italian). [Odonate taxa of 12 localities situated in Sicilia, Italy are listed; 15 species could be identified to the species level including a record of *Orthetrum trinacria*.] Address: Herren, B. & K., Oberfelderstr. 46, CH-3550 Langnau, Switzerland. E-mail: schule.rosig@bluewin.ch

biet München (Ephemeroptera, Plecoptera, Heteroptera, Coleoptera, Trichoptera u.a.). NachrBl. bayer. Ent. 50 (4): 113-127. (in German with English summary). ["Based on an actual study in streams and springs in the City of Munich records of aquatic insects from various orders are summarized. They are supplemented by data from recent literature. Some faunistically remarkable species are commented more in detail. By way of a resemblance analysis a faunistic classification is worked out, examining particularly the correspondence with hydrogeological / geo-morphological subunits of the Münchener Ebene within the city. The differentiated species communities are characterised and discussed with regard to the assumed near-natural state." (Authors) 8 odonate species including *Coenagrion mercuriale* are listed in tab. 1] Address: Hess, Monika, c/o ÖKOKART, Wasserburger Landstr. 151, D-81827 München, Germany. E-mail: info@oekokart.de

2417. Heymer, A. (2001): Gedanken zum "Vier-Beine-Sitzen" bei Libellen. Notul. odonotol. 5(8): 99-103. (in German with English summary). ["In odonates, the prothoracic legs serve, among other purposes, for holding prey while eating and, with the help of the specialised tibial combing spikes, they function as a "cleaning apparatus" for the head and the compound eyes. Thus, early in the hexapod evolution they have assumed the functions, which entailed that in some species the clasping reflex is no longer elicited during perching. Among the phylogenetically relatively young Libellulinae, the non-use of fore legs while sitting on substrate seems a general habit in Libellula and Orthetrum. Apparently, this behavioural peculiarity is to be considered a progressive feature in phylogeny. In the Zygoptera, this phenomenon has been so far recorded only in the euphaeid, *Dysphaea dimidiata*, which displays a perching behaviour convergent to that in Orthetrum." (Author)] Address: Heymer, A., Écologie Générale, Muséum National d'Histoire Naturelle, 4, Avenue du Petit Château, F-91800 Brunoy (Essone), France

2418. Hiemeyer, F.; Miller, E.; Miller, J. (2001): Winterbeobachtungen an *Sympetma paedisca* (Odonata: Libellula 20(3/4): 103-113. (in German with English summary). ["After several sightings in November 1997 and 1998, we systematically studied the behaviour of hibernating individuals at two ponds in the Allgäu, south-eastern Bavaria, Germany, in both following winters 1999/2000 and 2000/2001. They stayed during the winter in the shore vegetation of their breeding waters, sitting vertically on reedblades or horizontally on *Carex elata*. All were completely exposed to sun, wind, rain and snow. They safely survived snowing in, hoarfrost and freezing. If temperature was above 0 °C, the individuals were able to move and to crawl over snow, and if temperature was about 15 °C, they even could fly." (Author)] Address: Hiemeyer, F., Gögginger Str. 120, D-86199 Augsburg, Germany. E-mail: FritzHiemeyer@web.de

2419. Holder, M.; Kingsley, A. (2001): Summer 2000 peatland odonate surveys in New Brunswick and Nova Scotia, Canada. Argia 13(1): 17-19. (in English). [Examining peatland flora and fauna, 59 odonate species were spotted in 2000 including 30 new county records for the provinces of New Brunswick and Nova Scotia. *Somatochlora kennedyi* was recorded for the first time in Nova Scotia. *Leucorrhinia patricia* is considered a further remarkable record; the habitat of the species is

briefly characterised.] Address: Holder, M., Kingsley, Andrea, 4605 Hwy'12, Kentville, Nova Scotia B4N 3V8, Canada. E-mail: kingsley.holder@ns.sympatico.ca

2421. Huang, D.Y.; Lin, Q.B. (2001): The Early Cretaceous Hemeroscopid larva fossils from Beijing, China. Chin. Sci. Bull. 46(17): 1477-1481. (in English with Chinese summary). ["More than 100 hemeroscopid larva fossils were discovered from the Lower Cretaceous in southwest Beijing, which effectively ends the discussion of morphology and makes it more complete. It is assigned within the Libelluloidea, and shows close evolutionary correlations with modern Libellulidae. Although the wing characters of adult Hemeroscopus from the same formation indicates the close relationship to Aeschnoidea, we suggest that the larvae and the adults were the same species. Therefore, it probably shows the evolutionary ancestors of Libellulidae. Being the fundamental species discriminating Jehol Entomofauna and Lushangfen Entomofauna, Hemeroscopus bears great significance in the study of stratigraphy." (Author)] Address: Huang, D.Y., Acad. Sinica, Nanjing Inst. Geol. & Paleontol., Nanjing 210008, Peoples Rep. China

2422. Hünken, A.; Schütte, C. (2001): Im Trüben fischen: Predation von Flussbarschen auf Calopteryx-Larven. Abh. Ber. Naturkundemus. Görlitz 73(1): 33-34. (in German with English summary). ["Fishing in murky waters: Predation of perch on two Calopteryx species. - The role of turbidity in predator-prey interactions between *Perca fluviatilis* and *Calopteryx splendens* and *C. virgo* respectively was tested in laboratory experiments. In turbid water mortality induced by the fish was significantly higher in *C. splendens* as in *C. virgo*. *C. virgo* was less affected by predation of the fish than *C. splendens*, no matter if water was turbid or not. The differences between both Calopteryx species are discussed in terms of their life style." (Authors)] Address: Schütte C., Zool. Inst., TU Braunschweig, Fasanenstr. 3, D-38092 Braunschweig, Germany

2423. Huth, J. (2001): Libellen (Odonata) der Braunkohlen-Bergbaufolgelandschaft Sachsen-Anhalts. Abh. Ber. Naturkundemus. Görlitz 73(1): 35-37. (in German with English summary). ["From 1996 to 2000 altogether 47 species of dragonflies (75 % of the recorded species of Sachsen-Anhalt), including 21 endangered species of Sachsen-Anhalt and 22 endangered species of Germany, were found in the open-cast lignite post-mining landscapes of Sachsen-Anhalt. The importance of dragonflies of different types of post-mining waters are described, the most important of which is the nature reserve 'Schlauch Burgkernitz' near Bitterfeld. 40 species (including 17 endangered species of Sachsen-Anhalt and 19 endangered species of Germany) were found there." (Author)] Address: Huth, J., Oekokart GmbH, G.-Cantor-Str. 31, D-06108 Halle/Saale. E-mail: oekokart-halle@t-online.de

2424. Inoue, K. (2001): Non-contact sitting oviposition of *Sympetrum maculatum*. Sympetrum Hyogo 7/8: 2. (in Japanese with English summary). [*S. maculatum* fema-

les usually oviposit in tandem or single flight (non-contact flying oviposition), but a case of non-contact sitting oviposition was observed on October 20, 1990 at Sara Pond, Aonogahara, Ono City, Hyogo Prefecture, Japan. A few minutes later the female started to fly and oviposited in flight.] Address: Inoue, K., 5-9 Fuminosato 4-chome, Abeno-ku, Osaka 545, Japan

2425. Jakab, T.; Müller, Z.; Dévai, G. (2001): Quantitative survey of *Gomphus flavipes* (Charpentier, 1825) exuviae along River Tisza. Abh. Ber. Naturkundemus. Görlitz 73(1): 39. (in English with German summary). [In February 2000 accidentally cyanid-pollution penetrated the ecosystem of River Tisza, Hungaria. Along a 17 km stretch of this river *Stylurus flavipes* exuviae were sampled. Co-occurring species are *Ophiogomphus cecilia*, *Gomphus vulgatissimus*, *Platycnemis pennipes* *Calopteryx splendens*, *Ishnura elegans*, *Sympetrum vulgatum*, "*Cordulia aeneaturfosa*", and "*Crocothemis servilia*" (= *C. erythraea*). The author conclude that there was no negative influence of cyanid pollution resp. no drastic decrease in *S. flavipes* population.] Address: Devai, G., Department of Ecology, Kossuth L. University, H-4010 Debrecen, P.O. Box 71, Hungary

2426. Jeffries, M. (2001): The Northumbrian frontier of the Banded Demoiselle *Calopteryx splendens* (Harris). J. Br. Dragonfly Society 17(2): 55-58. (in English). [*C. splendens* is a species with a southern and midland distribution in England and Wales, declining in Yorkshire, and with an isolated northern outpost on the Solway Firth. More recent studies on the distribution of this species "show a stronger presence up through County Durham and one record north of the River Tyne in southern Northumberland. This paper describes the recent distribution of *C. splendens* within Northumberland (north of the River Tyne), from the time of its discovery in 1988. The extent of available habitat appearing suitable for further colonization is also considered." Address: Jeffries, M., Division of Geography and Environmental Management, Lipman Building, University of Northumbria, Newcastle upon Tyne, NE1 8ST, UK.

2427. Jödicke, R. (2001): Saisonale Einnischung von *Paragomphus genei* in Tunesien (Odonata: Gomphidae). *Libellula* 20(1/2): 13-22. (in German with English summary). ["On the basis of the seasonal pattern of emergence and the flying season the species can be best considered to be bivoltine. This life cycle is supposed to be typical of the West-Mediterranean populations; univoltinism may partly occur. In the southern oases a continuous emergence throughout the year was recorded, indicating a facultative multivoltinism." (Author)] Address: Jödicke, R., Großenging 14, D-49699 Lindern, Germany. 2430. Jones, C.D. (2001): *Somatochlora incurvata* (Incurvate Emerald) New to Algonquin Provincial Park, Ontario. In: Catling, P.M., C.D. Jones & P. Pratt (Eds): *Ontario Odonata*, vol. 2. Toronto Entomologist's Association, Toronto, Ontario: 47-48. (in English). ["*S. incurvata* [...] is reported from Algonquin Provincial Park, Ontario - representing the fourth location of this rare species in Ontario. With the inclusion of this species, the park's list of Odonata now stands at 99 species. The habitat is described as a sedge bog or poor fen, dominated by *Carex*, with *Sphagnum* and scattered clumps of *Chamaedaphne calyculata*. A female was observed ovipositing by dipping her abdomen into a shallow pool of water (30 x 30 cm) within the sedge-sphagnum mat." (Author)] Address: Jones, C.D., Box 182, Lakefield, Ontario, K0L 2H0, Canada. E-mail: colin.jones@mnr.gov.on.ca

2431. Kagimoto, B. (2001): The present state and the protection of the dragonfly, *Orthetrum poecilops miyajimaense* Yuki et Doi. *Nature and Insects* 36(7): 17-19. (in Japanese). [Introduction: *O. poecilops miyajimaense* is a rare species which inhabits only Miyajima in Hiroshima Prefecture in Japan, and is listed as an endangered species in RDB. This dragonfly was first discovered by Yuki, Jiro at Yamashiraura on Miyajima in 1936, and in 1955 by Dr. Sawano, Juzo it was rediscovered at the same point. After that the discovered spot had disappeared due to development. Also in Hiroshima Prefecture this species has been designated as a special wildlife species, which should be protected by the local governmental by law of Hiroshima. Collection of the species is prohibited and a violator will be sentenced to one year's penalty or fined 500 thousand yen. This species inhabit wetlands on the seashore, where rice grass, *Claudium chinense*, grows, and is rather tolerant of saline water. Development has been prohibited all over in Miyajima as a holy island, and the environment of the dragonfly has been preserved. The conditions of the environment for the species are as follows; (1) The wetland is always filled with spring water or by small streams which flow from the forests of the hinterland.

(2) The bed of the wetland is covered by the organic mud. (3) The sea water is quickly drained from the wetland. Only three well conditioned spots are left in the island. 1. Situation of the habitats: Habitat A: the southern limit on the island, which was pooled with sea water by the typhoon 19th of 1991 and the 18th in 1999 and damaged. The population decreased sharply. Habitat B: this habitat is located closely near to Habitat A, and rather well conditioned. Population is maintained in spite of the 19th typhoon. Habitat B: this habitat harbours the strongest population, and its ecological conditions are the best of the three locations 2. Measures for protection: The bylaw of prefectural government and municipal preservation activities for the habitats are helpful for the protection of the dragonfly. Also stock of larvae bred from eggs by members of Hiroshima Mushi no Kai has contributed to the increase of the population. 3. Prospect: The preservation of the habitats is most important. (1) Preservation of the forests of the hinterland. (2) Maintenance of shallow pools of sea water; drainage is important. (3) Precise investigation of the population size. (4) Preservation of the species from the view point all over the Inland Sea. Translation: Ishizawa, Naoya] Address: not stated

2432. Kalko, E. (2001): Bats gleaning dragonflies. *Argia* 13(1): 27. (in English). [Infrared filming of bats (*Micronycteris megalotis*) resulted that they prey using echolocation on sitting dragonflies] Address: Elisabeth.Kalko@biologie.uni-ulm.de

2433. Kamigaki, K. (2001): Intergeneric tandem of *Sympetrum frequens* male and *Pantala flavescens* female. *Sympetrum Hyogo* 7/8: 9. (in Japanese with English summary). [The intergeneric tandem was observed at Aonogahara, Ono City, Hyogo Prefecture, Japan on November 3, 2000. "They were flying swinging up and down, and perched on a grass on the margin of a pond, but flew away soon. They did not copulate during my observation."] Address: not stated

2434. Keil, R. (2001): Die Rolle von Libellen in der historischen Karpfenteichwirtschaft. *Abh. Ber. Naturkundes. Görlitz* 73(1): 41-43. (in German with English summary). ["Based on literature, considerations on the impact of carp farming on the occurrence and development of Odonata in historic fishery ponds are presented." 2435. Kerry, L. (2001): Habitat management for the Southern Damselfly *Coenagrion mercuriale* (Charpentier) on Aylesbeare Common, Devon. *J. Br. Dragonfly Soc.* 17(2): (in English). [A colony of *C. mercuriale* has been recorded intermittently at this site in low numbers since 1956. With the exception of 1986, when twelve individuals were recorded, the maximum count was four individuals for each year from 1977 to 1990. Two other colonies are present within 5 km of this site [...] Colaton Raleigh Common, has been recorded since 1963, with a maximum count of over 100 in 1986. [...] Venn Ottery Common, has been recorded since 1979, but only low numbers were recorded prior to the last sighting of a lone male in 1990. [...] The population of *C. mercuriale* at Aylesbeare Common has significantly increased since the advent of cattle grazing up to more than 300 specimens in 2001. "It is probable that the grazing is responsible for the increase in damselflies. Various factors may be important, for example the cattle poach the sub-

strate and create a mosaic of shallow pools; their droppings enrich the water; and their grazing alters the vegetation structure." The crucial parameter is unknown; therefore a PhD study will bring together the management regimes on other sites and establish the specific habitat requirements for *C. mercuriale*. "The future management at Aylesbeare will continue with light summer grazing, followed by brush cutting of small areas of Black Bog-rush (*Schoenus nigricans*) during the winter. The *C. mercuriale* population will continue to be monitored on a standard transect and the vegetation quadrats will be surveyed on a long-term basis." (Author)] Address: Kerry, L. Mount Pleasant, Stoneyford, Colaton Raleigh, Sidmouth, Devon EX 10 OHZ, UK

2436. Kitching, R.L. (2001): Food web in phytotelmata: "bottom-up" and "top-down" explanations for community structure. *Annu. Rev. Ent.* 46: 729-760, 1 Pl. excl. (in English). [The field study of food webs and the processes maintaining them is hampered by the sheer complexity and unreplicated nature of natural systems. The animal communities in phytotelmata, plant-held waters, are a convenient exception to this generalization. Tree holes, bamboo internodes, pitcher plants, tank bromeliads, and water-retaining plant axils contain a rich fauna, principally of arthropods, which constitute more or less complex, highly discrete food webs. They are widespread and replicated. The explanations for the community structure observed in these systems may call on "bottom-up" mechanisms such as simple environmental limitations, competition, predation, and facilitation, or they may adduce grander "top-down" theories, which explore biogeographic, energetic, dynamic, or biodiversity-related constraints. The existence of the bottom-up mechanisms is well established in experimental systems, and their consequences may be apparent in naturally occurring food webs. Top-down mechanisms demand a more holistic approach and are more difficult to test either by pattern analysis or experimental manipulation. The synoptic explanation of community composition and structure demands a multidimensional approach best expressed as a heuristic "template". Phytotelmata represent nearly ideal natural instruments for further study of food web dynamics, and exciting opportunities exist for the development and testing of community theories through their manipulation."] Address: Kitching, R., Aust. School Envir. Stud., Griffith Univ., Brisbane, Qld 4111, Australia

2437. Knaus, P.; Vorburger, C. (2001): Neuer Fundort von *Sympetma paedisca* in der Ostschweiz (Odonata: Libellulae). *Libellula* 20(1/2): 91-96. (in German with English summary). ["The species is threatened of extinction in Switzerland with the only actual breeding localities in the Valais and at Lake Constance (Untersee). We report on a new locality near St. Margrethen where *S. paedisca* was recorded regularly since 1994 in summer and autumn. Records derive from the northern slope of the »Heldsberg« at 420 - 440 m a.s.l., which is mainly covered with deciduous and coniferous forest. It is yet unclarified whether the species is autochthonous at the locality or whether the animals originated from the large population in the Rhine delta (Vorarlberg, Austria), approximately 5 km away." 2438. Knijff, G. de (2001): *Leucorrhinia pectoralis* (Charpentier, 1825) in 2000 in Vlaanderen: terug van

weggeweest of toch nooit volledig verdwenen? *Gomphus* 17(1): 9-22. (in Dutch with English and French summaries). ["*L. pectoralis* in 2000 in Flanders: back again or never disappeared? The last observations of *L. pectoralis* in Flanders date back from 1989 and this was the reason to consider this species in the red list as 'extinct in Flanders'. In 2000 however, *L. pectoralis* was observed at 5 different localities and altogether 10 individuals were noted. At one site one tandem and a third individual were observed. All these sites are situated in the Campine (Kempen), 4 in the province of Antwerp (Kalmthout, Herentals and Mol, twice) and one in the province of Limburg (Opglabbeek). From those 5 sites, *L. pectoralis* had only been observed in the past in Opglabbeek. The habitats where *L. pectoralis* was observed in 2000 are an acidified fen (twice), a humic acid fen, a mesotrophic pond and a nutrient poor peatbog with seepage chalk water. All the observations of *L. pectoralis* in 2000 are situated between the 13th of May and the 11th of July. This corresponds completely with the old observations from Flanders. It is impossible to track the origin of the individuals seen in 2000. Considering the great distance (>150 km) to the known populations in Northwestern Europe and the fact that 10 individuals were seen within a time period of two months, we presume that at least the majority, if not all, of the individuals have emerged in Flanders and that there still exist one or more populations in Flanders. Extra arguments for this reasoning are the facts that the optimal habitat of *L. pectoralis* is only accessible with difficulty for men, the usually small number of individuals in a population and the short flying period. We suggest that the Red list status of *L. pectoralis* should now be considered 'Critically endangered' in Flanders." (Author)] Address: Knijf, G. de, Instituut voor Natuurbehoud, Kliniekstraat 25, B-1070 Brussel, Belgium. E-mail: geert.de.knijf@instnat.be

2439. Krech, M. (2001): Ein Beitrag zur Libellenfauna nordostdeutscher Regenhochmoore - Das NSG Gölde-nitzer Moor bei Cammin. (Landkreis Bad Doberan). Archiv Freunde Naturgeschichte in Mecklenburg 40: 161-172. (in German). [The Gölde-nitzer Moor is one of the classical odonatological localities in Germany (see W. Rabeler, 1931, who lists 20 species). Additional surveys in the 1980ies increased the species list, and today 39 species are known, 24 to be autochthonous. Bog species are well represented; the rare *Aeshna subarctica elisabethae* continuously is known from the 1920ies. Interesting is the reproduction of *Anax imperator* in an dystrophic water body. The bog is threatened by peat harvesting, melioration and succession of vegetation in the water bodies used for reproduction.] Address: Krech, M., Auf der Großen Mühle 7, D-99198 Erfurt, Germany

2440. Kreuz, P.; Arnold, W.; Kesel, A.B. (2001): Acoustic microscopic analysis of the biological structure of insect wing membranes with emphasis on their waxy surface. Annuals Biomedical Engineering 29(12): 1054-1058. (in English). ["The mechanical performance of natural materials depends on the type, and especially the composition of the molecular constituents. They are almost without exception composite materials, whose characteristics are determined by the characteristics of the individual constituents, their shape, their interaction, and in particular their orientation within the natural material. One of the most impressive natural composites is the insect cuticle. This lightweight building material im-

presses one with its ability to withstand extremely heavy loading. Even the ultrathin (3-10 µm) membranes of insect wings add greatly to the structural stability of the wings. By means of acoustic microscopy, the present study also shows that the thin covering of wax on the membrane is not an accidental material arrangement. Contrary to that of locust wings, dragonfly (*Aeshna cyanea*) wing membranes were found to have a criss-cross fiber-like density gradient within to the waxy layer. This density gradient proved to be mechanically relevant in stabilizing the wings." [42 stretches of running waters in the Federal State Nordrhein-Westfalen, Germany are characterised and documented in detail; such stretches with reference character can

serve to develop so called "Leitbilder" (strategic models, ecological goal functions) for revitalisation measures along additional stretches of the same water or comparable waters in the catchment area. Macrozoobenthos of the stretches is also compiled including odonate taxa, in most cases *Calopteryx virgo*, *C. splendens*, *Platycnemis pennipes*, and *Gomphus vulgatissimus*. *Onychogomphus forcipatus* is documented for the river Eder. *Ischnura elegans*, *Coenagrion puella*, *Pyrrhosoma nymphula*, and *Chalcolestes viridis* are documented for a few rivers with slow current.] Address: Landesumweltamt NRW, PF 102363, D-45023 Essen, Germany

2450. Legrand, J. (2001): *Malgassophlebia mayanga* (Ris, 1909) et une nouvelle espèce du genre à Madagascar (Odonata, Anisoptera, Libellulidae). *Revue Française d'Entomologie (Nouvelle Série)* 23(4): 225-236. (in French with English summary). [Male, female, and last instar larvae of *Malgassophlebia mayanga* (Ris 1909) are redescribed. Male, female, and last instar larvae of *Malgassophlebia mediodentata* n.sp. (holotype male, allotype female, 7/XI/1998, Bassin du Rianila, 15 km east of Morarano, Madagascar) are described. Both species are illustrated and compared in detail. Larval characters, allied species, biology, and distribution are briefly discussed.] Address: Legrand, J., 10, rue du Chemin de fer, F-94110 Arcueil, France

2451. Leipelt, K.G.; Schütte, C.; Suhling, F. (2001): Neue Daten zur Larvalökologie von *Macromia splendens* (Odonata: Macromiidae). *Libellula* 20(1/2): 1-11. (in German with English and French summaries). ["At the end of July, 1998, in mid July, 1999, and in mid June, 2000, a total of 67 larvae was recorded at a section of about 100 m in length at the Garden de Mialet in the mountain range of the Cevennes, southern France. Only one larval generation, comprising up to four different stadia was found during June and July. Another generation was on the wing, the third was in the egg stage. Therefore the duration of larval development is considered to last two years in that region. All larvae were found in reaches where the water current was hardly noticeable: We recorded 53 larvae at sandy patches in shallow water near the river margin, five in deposits of a mixture of twig, leaf and fine detritus, and nine on bedrock in about 1 m water depth. In other microhabitats like alder roots, gravel and boulder no larvae were found." (Authors)] Address: Leipelt, K.G., Zoologisches Institut -Ökologie-, Technische Universität Braunschweig, Fasanenstr. 3, D-38092 Braunschweig, Germany. E-Mail: k.leipelt@tu-bs.de

2452. Leipelt, K.G.; Sommer, R.; Martens, A. (2001): Territorialität bei *Oxygastra curtisii* (Odonata: Corduliidae). *Libellula* 20 (3/4): 155-170. (in German with English summary). ["In the Cevennes mountains, southern France, males patrolled continuously at 6-15 m long stretches at the river margin. They defended their territories against conspecific males. In the territories patrol flights of individual marked males lasted between less than one and up to 28 minutes. Within one hour males patrolled in up to four different territories." (Authors) In addition information on habitat preference and activity patterns in relation to temperature and rain of *Boyeria irene* are given.] Address: Leipelt, K.G., Zool. Inst. -Ökologie-, Technische Universität Braunschweig, Fasanenstr. 3, D-38092 Braunschweig, Germany. E-Mail: k.leipelt@tu-bs.de

- 2460.** Marden, J.H.; Fitzhugh, G.H.; Girgenrath, M.; Wolf, M.R.; Girgenrath, S. (2001): Alternative splicing, muscle contraction and intraspecific variation: associations between troponin T transcripts, Ca_{2+} sensitivity and the force and power output of dragonfly flight muscles during oscillatory contraction. *J. Exp. Biol.* 204(20): 3457-3470. (in English). ["The flight muscles of *Libellula pulchella* dragonflies contain a mixture of six alternatively spliced transcripts of a single troponin T (TnT) gene. Here, we examine how intraspecific variation in the relative abundance of different TnT transcripts affects the Ca_{2+} sensitivity of skinned muscle fibers and the performance of intact muscles during work-loop contraction regimes that approximate in vivo conditions during flight. The relative abundance of one TnT transcript, or the pooled relative abundance of two TnT transcripts, showed a positive correlation with a 10-fold range of variation in Ca_{2+} sensitivity of skinned fibers ($r(2)=0.77$, $P < 0.0001$) and a threefold range in peak specific force ($r(2)=0.74$, $P < 0.0001$), specific work per cycle ($r(2)=0.54$; $P < 0.0001$) and maximum specific power output ($r(2)=0.48$, $P=0.0005$) of intact muscle. Using these results to reanalyze previously published data for wing kinematics during free flight, we show that the relative abundances of these particular transcripts are also positively correlated with wingbeat frequency and amplitude. TnT variation alone may be responsible for these effects, or TnT variation may be a marker for changes in a suite of co-regulated molecules. Dragonflies from two ponds separated by 16 km differed significantly in both TnT transcript composition and muscle contractile performance, and within each population there are two distinct morphs that showed different maturational trajectories of TnT transcript composition and muscle contractility. Thus, there is broad intraspecific variability and a high degree of population structure for contractile performance phenotypes, TnT ribotypes and ontogenetic patterns involving these traits that affect locomotor performance." ["At the rendezvous males prefer stones as perches. Discrimination experiments with pairs of substrates showed that males land preferentially on perches that correspond in height to the flight level of females appearing at the water. When they first landed males preferred perches in the middle of the stream, but afterwards they used perches near the stream margin. The results are interpreted in terms of early recognition of females and rapid formation of tandem linkage." (Author)] Address: Martens, A., Zool. Inst. TU Braunschweig, Fasanenstr. 3, D-38092 Braunschweig, Germany. E-mail: andreas.martens@tu-bs.de

2471. Müller, J.H. (2001): Neue Erkenntnisse zu Ökologie und Verbreitung der Sibirischen Azurjungfer *Coe-*

nagrion hylas. mercuriale 1: 9-12. (in German). [This is a compilation of the significant results of an extensive study (see OAS 2171) of the most rare damselfly of central Europe. Reproduction habitat, hunting habitat (up to 500 m away from reproduction habitat), diurnal activity rhythms, emergence curve, and phenology of the species are outlined. The significant increase of knowledge on ecology of the extremely rare species enlarges the chance to preserve it in central Europe. Conservation measures are developed in the framework of a LIFE-project financed by the EU and realised by WWF-Austria.] Address: Müller, J.M., Goethestr. 25, D-89601 Schelklingen, Germany. E-mail: Libellen@Jo-chen.de

2472. Müller, O.; Müller, B. (2001): Armeleuchteralgen als Substrat für Larven von *Onychogomphus forcipatus* (Odonata: Gomphidae). *Libellula* 20(1/2): 69-78. (in German with English summary). ["In an oligotrophic mining lake in Brandenburg, Germany, larvae of *O. f. forcipatus* were found in pads of the Common Stonewort *Chara contraria* (Charophyceae: Characeae). Under laboratory conditions, given the choice between stoneworts and bare sand the larvae preferred stoneworts significantly, but they showed no significant preference when the sand was covered by detritus. The pads provide different microhabitats for larvae of gomphid dragonflies. Under artificial conditions in the laboratory, *O. forcipatus* larvae were usually found buried in the basal layer which consist of rotting material and *Chara* rhizoids. Some larvae were also recorded sitting in the *Chara* thalli and waiting for prey. The use of different microhabitats is interpreted as an anti-predator behaviour and adaptive behaviour to improve the efficiency of hunting as well." (Authors)] Address: Müller, O., Birkenweg 6d, D-13206 Libbenichen, Germany. E-mail: olemueller@freenet.de

2473. Müller, O.; Müller, B. (2001): Sand oder Algen? Habitatwahlverhalten der Larven von *Onychogomphus f. forcipatus* (L., 1758). *Abh. Ber. Naturkundemus. Görlitz* 73(1): 63. (in German with English summary). ["In an oligotrophic mining lake in Brandenburg, larvae of *Onychogomphus f. forcipatus* were found in pads of the stonewort *Chara contraria* (Charophyceae: Characeae). Habitat selection experiments showed that *O. forcipatus* prefers algal pads to bare sand. The use of different microhabitats in the pads is interpreted as an anti-predator behaviour and as an adaptive behaviour to improve the efficiency of hunting." (Authors)] Address: Müller, O., Birkenweg 6d, D-13206 Libbenichen, Germany. E-mail: olemueller@freenet.de

2474. Müller, Z.; Jakab, T.; Szállassy, N. (2001): Faunistic data on dragonflies (Odonata) from the inundation area of River Tisza between Tiszabercel and Balsa. *Studia odonatol. hung.* 7: 39-58. (in Hungarian with English summary). [Hungary; in 1998 and 1999, 22 localities were surveyed for their Odonata. A total of 34 species were recorded. The species list include *Brachytron pratense*, *Epitheca bimaculata*, and *Stylurus flavipes*.] Address: Müller, Z., Dept of Ecology, Kossuth L. University, H-4010 Debrecen, P.O. Box 71, Hungary

2475. Müller, Z.; Jakab, T.; Devai, G.; Szállassy, N. (2001): The effect of habitat degradation on dragonfly assemblages on the floodplain of the River Tisza. *Abh. Ber. Naturkundemus. Görlitz* 73(1): 65-66. (in English with German summary). [The floodplain of River Tisza

including many backwaters plays an important role as a core area in the conservation of biodiversity in Hungary. In spite of this these water bodies are effected by numerous unfavourable human impacts (intense agricultural, forestry and angling utilisation). The aims of the study (conducted 1998 and 1999) were to answer the questions: (i) how biotope and habitat differences caused by the different intensity of angling are related and (ii) what kind of connection exists between the intensity of angling and some variables of dragonfly assemblages: "(i) the presence-absence data of dragonfly species show that habitat-level differences caused by the different intensity of angling within a specific water body can exceed biotope-level differences among water bodies of different types, (ii) the species number of dragonfly assemblages and the summarised data number relative abundance of the 5 rarest species of the floodplain section decrease parallel with the increase in the intensity of angling utilisation according to linear relation, at the same time the summarised data number relative abundance of the 5 most frequent species increases."] Address: Müller, Z., Dept of Ecol., Kossuth L. University, H-4010 Debrecen, P.O. Box 71, Hungary

2476. Nawroth, J. (2001): Libellen an der lykischen Küste (Türkei). *Naturkundliche Beiträge des Deutschen Jugendbund für Naturbeobachtung* 34: 3-4. (in German). [Some notes from a travel along the lykian coast (Turkey). Some odonate species are referred, but no localities are given. None of the specimens was collected, and all identifications are doubtful due to insufficient identification literature used.] Address: Nawroth, Janna, Johann-Fischer-Str. 21, D-69121 Heidelberg, Germany

2477. Nel, A.; Bethoux, O.; Bechly, G.; Martinez-Delclos, X.; Papier, F. (2001): The Permo-Triassic odonoptera of the "protodonate" grade (Insecta: Odonoptera). *Ann. Soc. Entomol. Fr.* 37(4): 501-525. (in English with French summary). ["We describe a new fossil dragonfly *Permophlebia uralica*, gen. n., sp. n. that we attribute to a new family *Permophlebiidae*. Several Permo-Triassic odonate taxa are redescribed, viz. the taxa of the family *Triadotypidae*, and the genera *Kargalotypus* Rohdendorf, 1962, and *Liadotypus* Martynov, 1937. Their phylogenetic positions are discussed, and some earlier taxonomic decisions re-evaluated. The *Piroutetiidae* Nel, 1989 is transferred in the *Triadophlebiomorpha*, superfamily undetermined sit. nov. The *Kargalotypidae* Zessin, 1983 is transferred in the *Triadophlebiomorpha*: *Zygophlebiida* sit. nov. The *Liadotypidae* Grauvogel & Laurentiaux, 1952 (non Martynov, 1937) is transferred in the *Isophlebiida* sit. nov. family incertae sedis stat. nov. The cladistic analysis of the *Zygophlebiida* (new clade) is proposed." (Authors)] Address: Nel, A., Lab. Ent. Mus. Natn. Hist. Nat., 45 rue Buffon, F-75005 Paris, France. E-mail: anel@cimrs1.mnhn.fr

2478. Nielsen, O. F. (2001): *Anax imperator* - records in Denmark in the period 1994 - 2000. *Nord. Odonat. Soc. Newsl.* 7(1): 12-13. (in Danish with English summary). ["*A. imperator* was first recorded in Denmark in 1994, in SW-Jylland (Jutland). Later the species has been found at several new localities, also at the islands Fyn and Sjælland. It is now known from seven localities, both lakes poor on nutrients and richer ponds and lakes." (Author)] Address: Nielsen, O.F., Tulstrupvej 112, DK-8680 Ry, Denmark

- 2479.** Nielsen, O. F. (2001): *Ischnura pumilio* - a description of the larva and a comparison with the larva of *Ischnura elegans*. Nord. Odonat. Soc. Newsl. 7(1): 14. (in Danish with English summary). ["8 larvae of *I. pumilio* from the Ry area were hatched under controlled conditions in 1999, 10-13 days after they were collected 8 April. Nordic larvae of *I. pumilio* have not been described before, so a short description is given here. Most of these exuviae and also a number of larvae were pale (reddish yellow, pale brown), some darker brown or almost black. Femura without dark ring. Gills pale with pale or reddish brown trachea. Weak contrast between trachea and the rest of the gill, few and sparsely branched side-trachea. Gills with long pointed tips, the white tip clearly visible in 10x magnification." (Author)] Address: Nielsen, O.F., Tulstrupvej 112, DK-8680 Ry, Denmark
- 2480.** Nielsen, O. F. (2001): Surveillance of 6 of the red-listed dragonflies in Denmark. Nord. Odonat. Soc. Newsl. 7(1): 6-10. (in Danish with English summary). ["The situation for six of the red-listed dragonfly species in Denmark the last ten years is surveyed and discussed. *Coenagrion armatum* (E) has disappeared at the old localities that have been investigated, and is only known from three localities in the last decade. *Aeshna viridis* (V) still seems to be present at a few localities in two areas, and is also recorded more accidentally (?) in other places. *Ophiogomphus cecilia* (R) still occurs in fairly good numbers in three of the four river systems where it has been recorded. *Libellula fulva* (E) is still living in good numbers at four clean lakes and one stream. Only one female of *Orthetrum coerulescens* (E) has been seen in Denmark since 1935, in 1991, but a possible occurrence could not be confirmed in the investigations of the last years. *Leucorrhinia pectoralis* (E) has only been found present at four of the about twenty previous known localities.] Address: Nielsen, O.F., Tulstrupvej 112, DK-8680 Ry, Denmark
- 2481.** Nikula, B.J.; Sones, J.L.; Trimble, J.R. (2001): New and notable records of Odonata from Massachusetts. Northeastern Naturalist 8(3): 337-342. (in English). [The occurrence of six species of Odonata previously unknown from Massachusetts, USA is documented: *Ischnura prognata*, *Aeshna subarctica*, *Somatochlora incurvata*, *Gomphaeschna antilope*, *Libellula axilena*, and *Tamea calverti*. Four of these species were unknown from New England prior to 1995. Additionally, recent records of *Somatochlora georgiana* and *Sympetrum corruptum*, two species rarely recorded from New England, are discussed.] Address: Nikula, B., 2 Gilbert Lane, Harwich Port, MA 02646, USA. E-mail: odenews@capecod.net
- 2482.** Nishu, S. (2001): *Aeshna mixta soneharai* caught in Toyano-gata Pond, Niigata Prefecture. *Sympetrum Hyogo* 7/8: 23. (in Japanese with English summary). [Japan; the first regional records of *Aeshna mixta soneharai* are documented.] Address: Nishu, S., 247 Gunge Shonomoto, Mikage-cho, Higashinda-ku, Kobe, Hyogo, 658-0057, Japan. E-mail: Snishu@mx2.nisiq.net
- 2483.** Nishu, S.; Azuma, T. (2001): Northern record of *Ictinogomphus pertinax* in the southern part of Hyogo Prefecture. *Sympetrum Hyogo* 7/8: 22-23. (in Japanese with English summary). [Eleven new habitats of this southern species were discovered in 2000. The habitats include two in Ono City which are the northernmost record in Hyogo Prefecture, Japan.] Address: Nishu, S., 247 Gunge Shonomoto, Mikage-cho, Higashinda-ku, Kobe, Hyogo, 658-0057, Japan. E-mail: Snishu@mx2.nisiq.net
- 2484.** Nishu, S. (2001): Record of the odonate fauna of Dragonfly Pond in Kyoto Gyo-en, Kyoto Prefecture. *Sympetrum Hyogo* 7/8: 74-75. (in Japanese with English summary). ["The so-called Dragonfly Pond in Kyoto Gyo-en was built in 1994 or 1995, and a survey on the odonate fauna was made on March 6, 1997 by four members including the author. Larvae of four species including *Libellula quadrimaculata asahinai*" which is an addition to the twenty recorded by Tsukamoto et al. (1995). Deep shading by *Nelumbo nucifera* is responsible for the poor odonate fauna at the pond.] Address: Nishu, S., 247 Gunge Shonomoto, Mikage-cho, Higashinda-ku, Kobe, Hyogo, 658-0057, Japan. E-mail: Snishu@mx2.nisiq.net
- 2485.** Nishu, S. (2001): Report of the survey trips of the Hyogo Society of Odonatology in 1999. Part 1 focused to *Libellula angelina*. *Sympetrum Hyogo* 7/8: 53-56. (in Japanese with English summary). ["Survey trips [...] were held on April 29, May 2 and May 15, 1999 at Sara Pond in Ono City, Japan, but no *angelina* was found. On the contrary, about one hundred *angelina* were found at a pond in Kasai City on May 15, 1999. This pond had been inhabited by a good number of *angelina* before 1996, but the population was destroyed by the civil works which destroyed the bank and the water was removed for a few years." The origin of the immigrating specimens is not known.] Address: Nishu, S., 247 Gunge Shonomoto, Mikage-cho, Higashinda-ku, Kobe, Hyogo, 658-0057, Japan. E-mail: Snishu@mx2.nisiq.net
- 2486.** Nishu, S. (2001): Report of the survey trips of the Hyogo Society of Odonatology in 1999. Part 2 focused to *Mortonagrion hirosei* and *Stylurus ngoyanus*. *Sympetrum Hyogo* 7/8: 57-61. (in Japanese with English summary). [Both species were surveyed during June 26-27 visiting Momoshima Pond and its vicinities, Funa-machi, Toyo-oka City along Maruyama River and Izushi-cho along Izushi River, Japan. Abundance of adult *M. hirosei* was quite low, but the larval population was high, presumably due to the visit in the early season of the species. 19 exuviae of *S. ngoyanus* were found at the bank of Maruyama River some 7 km downstream of the oviposition sites. This is the first discovery of the emerging site of this species in Hyogo Prefecture. Tables with localities and accompanying species are included in this paper.] Address: Nishu, S., 247 Gunge Shonomoto, Mikage-cho, Higashinda-ku, Kobe, Hyogo, 658-0057, Japan. E-mail: Snishu@mx2.nisiq.net
- 2487.** Nishu, S. (2001): Report of the survey trips of the Hyogo Society of Odonatology in 2000. Part 1 focused to *Libellula angelica*. *Sympetrum Hyogo* 7/8: 62-66. (in Japanese with English summary). [*L. angelina* was surveyed on April 30, May 14 and 21, 2000 at some localities including the Pond A, B and C in Kasai City, with a strong population of the species. The author takes it for very likely "that females judge whether a pond is suitable for larval growth or not, and they will not be attracted by males in their territory if females judge negatively." Sara Pond was also surveyed, but no *angelina* was found in 2000.] Address: Nishu, S., 247 Gunge

Shonomoto, Mikage-cho, Higashinda-ku, Kobe, Hyogo, 658-0057, Japan. E-mail: Snishu@mx2.nisiq.net

2488. Nishu, S. (2001): Report of the survey trips of the Hyogo Society of Odonatology in 2000. Part 2 focused to *Chlorogomphus brunneus costalis*. *Sympetrum Hyogo* 7/8: 67-69. (in Japanese with English summary). ["Four localities in Tokushima Prefecture were visited by members of the Hyogo Society of Odonatology during June 24-25, 2000. Larvae, exuviae and imagoes of *C. brunneus costalis* were found at two localities, and those of *Rhipidolestes hiraoui* were found at three localities." To trace *Chlorogomphus* in the southern part of Awaji Island failed.] Address: Nishu, S., 247 Gunge Shonomoto, Mikage-cho, Higashinda-ku, Kobe, Hyogo, 658-0057, Japan. E-mail: Snishu@mx2.nisiq.net

2489. Nishu, S. (2001): Report of the survey trips of the Hyogo Society of Odonatology in 2000. Part 3 focused to *Mortonagrion Hirosei* and *Stylurus nagoyanus*. *Sympetrum Hyogo* 7/8: 71-73. (in Japanese with English summary). ["Many imagoes and larvae of *M. Hirosei* were found at Momoshima Pond on July 15 and 16, 2000. The pond was partly filled up by the construction civil works of a sewage treatment plant, but it is proved that the habitat of this coenagrionid damselfly was not influenced. Exuviae and emergence of *S. nagoyanus* were observed at the bank of Maruyama River and exuviae of this species were found also at Izushi River." (Author)] Address: Nishu, S., 247 Gunge Shonomoto, Mikage-cho, Higashinda-ku, Kobe, Hyogo, 658-0057, Japan. E-mail: Snishu@mx2.nisiq.net

2490. Nishu, S. (2001): *Tramea virginia* observed at the Expo Site of Japan Flora 2000. *Sympetrum Hyogo* 7/8: 21. (in Japanese with English summary). [*T. virginia* was found at a newly constructed pond at the Expo Site of Japan Flora 2000 on August 25, 2000. 2491. Norma-Rashid, Y.; Mohd-Sofian, A.; Zakaria-Ismail, M. (2001): Diversity and distribution of Odonata (dragonflies and damselflies) in the fresh water swamp lake Tasek Bera, Malaysia. *Hydrobiologia* 459: 135-146. (in English). ["Fifty-nine species of Odonata were collected in a recent study in the freshwater swamp lake of Tasek Bera, Peninsular Malaysia, in contrast to 33 species that were recorded previously from the Ramsar site. This study added 35 species to the odonate records and together with the museum records, the number of species for the site now stands at 78 from 12 families. The causal factors for the absence of 19 species and other biological aspects such as habitat clustering and temporal activity profile were discussed." (Authors)] Address: Norma-Rashid, Y., Univ. Malaysia, Fac. Sci., Inst. Biol. Sci., Kuala Lumpur 50603, Malaysia

2492. Ochsner, E. (2001): Libellen - Kleinodien unserer Gewässer. *Insektenkurier* 70: 28-33. (in German). [This popular, but well written introduction into dragonflies is published in a journal of stamp collectors with interest in insects. The paper is illustrated with stamps from different countries showing dragonflies. A checklist of German dragonflies is appended.] Address: Ochsner, E., Schulstr. 4, CH-8640 Rapperswil, Switzerland

2493. Ochsner, E. (2001): Plattbauch-Segellibelle - Insekt des Jahres 2001. *Insektenkurier* 70: 27. (in German). [*Libellula depressa* was elected the "Insect of the year 2001"; the author introduces into several aspects of this dragonfly with special emphasize to the name, habitat, and habits. Because the 'Insektenkurier' is a journal for stamp collectors with interest in insects, the species is illustrated by a stamp issued by the German Bundespost in 1991.] Address: Ochsner, E., Schulstr. 4, CH-8640 Rapperswil, Switzerland

2494. Oda, I. (2001): Some observations on the behaviour of *Sympetrum frequens*. *Sympetrum Hyogo* 7/8: 50-53. (in Japanese with English summary). [During a stay at a hospital in Yonago City, Tottori Prefecture, Japan during October 17-31, 1999, the behaviour of *S. frequens* was observed. The Yone River was degraded to a concrete channel, but after flooding it with water ("First stage"), tandems of this species passed over the river, but without taking any attention. When the water table diminished to 3 to 4 cm depth and current velocity receded to zero ("Second stage"), "some pairs came down, but flew away, while the other pairs passed by without attention". When the water table diminished more strong, leaving only splashes ("Third stage"), 100% of tandems used it for oviposition. [...] "Two modes of oviposition were recognized based on 11 cases in which tandem pairs visited Yone River. One is called "tentative oviposition" and another "substantial oviposition". In tentative oviposition pairs oviposit slowly for a short while, then they copulate and oviposit again. In substantial oviposition pairs oviposit rapidly for a longer while, and they separate after oviposition, sitting separated without paying any attention to the former partner.] Address: not stated

2498. Ott, J. (2001): Erfahrungen aus der Planungspraxis bei Monitoringstudien mit Libellen. Abh. Ber. Naturkundemus. Görlitz 73(1): 67-68. (in German with English summary). ["Four monitoring studies, which all took place in different parts of the German federal state Rhineland-Palatinate, are presented. The studies covered the long-term impact of fish stocking on the dragonfly fauna of a gravel pit, the constant changing of the fauna of some shallow waters, control of the success of a restoration measure, and finally the monitoring of a possible future impact on wetlands as a consequence of groundwater extraction." (Author)] Address: Ott, J., Friedhofstr. 28, D-67705 Trippstadt, Germany. E-mail: L.U.P.O.GmbH@t-online.de

2499. Ott, J. (2001): Expansion of Mediterranean Odonata in Germany and Europe - consequences of climatic changes. In: Walther, G.-R., C.A. Burga & P.J. Edwards (Eds.): "Fingerprints" of Climate Change. Kluwer Academic/Plenum Publishers. New York, Boston, Dordrecht, London, Moscow: 89-111. (in English). ["Whereas a few years ago a clear northward expansion was shown only for the dragonfly *Crocothemis erythraea*, a Mediterranean element of the German dragonfly fauna, now for a lot of dragonflies a comparable situation is very obvious. In this paper an overview of recent expansion of many dragonfly species in Germany and Europe is given, as well as some information on the biological and ecological consequences. Beside this clear trend of expansion towards the north, the increase of population sizes and the colonisation of biotopes in higher altitudes, also several biological and behavioural adaptations could be registered, which are shown in detail. Consequences and scenaria for the future of several dragonfly species and for the aquatic systems as a whole are pointed out." (Author).] Address: Ott, J., L.U.P.O. GmbH, Friedhofstrasse 28, D-67705 Trippstadt, Germany

2500. Ott, J. (2001): Zum Einsatz von Libellen als Bioindikatoren und Monitoringorganismen in Feuchtgebieten - das Beispiel einer geplanten Wasserentnahme im Naturschutzgebiet «Täler und Verlandungszone am Gelterswoog» (Biosphärenreservat Pfälzerwald). Ann. Sci. Rés. Bios. Trans. Vosges du Nord-Pfälzerwald 9: 151-177. (in German with French and English summaries). ["In a system of valleys measuring approximately 50 hectares, to the south west of Kaiserslautern, the extraction of approximately one million m³ of ground water is planned from the year 2001 onwards in the «Valleys and alluvial zones in the Gelterswoog». To ensure that this water extraction does not create any significant damage to the area's important flora and fauna, ecological monitoring with intensive studies of flora and fauna has been carried out since 1998. As part of this, individual aspects of dragonfly species have been presented, and related back to previous examinations of the same area. In total in the most varied wet, habitat rich areas (streams, low-lying marshland, dystrophic ponds, alluvial zones, fallow lands, etc.) 33 species of dragonflies have been recorded thus far, [...] including 23 species on the Rheinland-Pfalz Red List and 17 species on the German National Red List. It has so far, except for individual fish stocking measures and local water management operations, as well as natural succession, established only few massive damaging factors for the dragonfly population. In addition to the high degree of diversity and mosaic type of habitats it is above all remarkable for its almost barrier free composi-

tion. The number of indigenous species is relatively constant and the annual turnover of species throughout the whole area is low. One indigenous species that has now disappeared is *Calopteryx splendens*, but on the other hand the following species have re-established themselves and are breeding successfully: *Gomphus pulchellus*, *Brachytron pratense*, *Anax imperator*, *Sympetma fusca*, and *Erythromma viridulum*. As regards species protection, the most significant species in the area in addition to *Coenagrion hastulatum*, *Orthetrum coerulescens* and *Leucorrhinia dubia* is *Somatochlora arctica*. The possibilities for using dragonflies as bioindicators and monitoring organisms are explained in detail as an example of possible reactions to changes in water level." (Author)] Address: OTT, J., L.U.P.O., Friedhofstrasse 28, D-67705 Trippstadt, Germany

2501. Parr, A. (2001): Migrant and dispersive dragonflies in Britain during 2000. J. Br. Dragonfly Society 17 (2): 49-54. (in English). ["The year 2000 was perhaps not as dramatic for migrant Odonata in Britain as, for example, 1995 or 1998, but there were a number of highlights. Most notably, high numbers of *Sympetrum fonscolombii* arrived for the third time in the last five years and several other unusual migrant species were recorded. Two main periods of immigration took place. A brief hot spell in mid-June saw a significant arrival of migrant insects, including dragonflies such as *S. fonscolombii*, *Anax parthenope* and a single *Crocothemis erythraea*. During late-July, further arrivals of *Anax parthenope* and *S. fonscolombii* were observed. The first wave of immigration pushed quite far north; the record of *A. parthenope* from Orkney represents the most northerly record for this species in Europe. Complementing the events in Britain, three species new to Ireland (*Aeshna mixta*, *A. imperator*, *A. parthenope*, were recorded during the year." (Author). Additional species treated are: *Calopteryx splendens*, *Ceriagrion tenellum*, *Erythromma viridulum*, *Aeshna grandis*, *Cordulia aenea*, *Libellula quadrimaculata*, *L. depressa*, *Orthetrum cancellatum*, *Sympetrum striolatum*, *S. sanguineum*, and *S. flaveolum*. Some observations referring *A. grandis*, *A. imperator*, and *S. striolatum* attracted by UV light resp. moth traps are of general interest.] Address: Parr, A.J., 10 Orchard Way, Barrow, Bury St. Edmunds, Suffolk IP29 5BX, UK

2502. Paulson, D. (2001): A Venezuelan odonate vacation. Argia 13(1): 7-9. (in English). [The trip in the dry season to Venezuela turned out - from the odonatological view - to be quite "disappointing". 500+ specimens in 102 species could be collected among them *Phyllogomphoides major* Belle 1984, *Erythemis credula* (Hagen 1861), *Neoneura cristina* Rácenis, 1955, *Neoneura luzmarina* De Marmels 1989, *Neoneura sylvatica* Hagen in Selys 1886, and *Oligoclada sylvia* (Kirby 1889). New species for Venezuela are *Phyllocycla bartica* Calvert 1948, *Idiataphe cubensis* (Scudder 1866), *Micrathyrina dunklei* Westfall 1992, and *Micrathyrina occipita* Westfall 1992.] Address: Paulson, D.R., Slater Museum, Univ. of Puget Sound, Tacoma, WA 98416, USA. E-mail: dpaulson@ups.edu

2503. Paulson, D. (2001): Review: Dragonflies through binoculars - A field guide to dragonflies of North America. Science 293(5537): 2005. (in English). [Review of Sid Dunkle's book on North America Anisoptera.] Address: Paulson, D.R., Slater Museum, Univ. of

2505. Pavey, C.R.; Burwell, C.J.; Grunwald, J.E.; Marshall, C.J.; Neuweiler, G. (2001): Dietary benefits of twilight foraging by the insectivorous bat *Hipposideros speoris*. *Biotropica* 33(4): 670-681. (in English). ["Although bats are nocturnal, many species emerge from roosts to forage during twilight, despite a presumed high risk of predation at this time. Here, we describe twilight foraging by a maternity colony of Schneider's leafnosed bat (*Hipposideros speoris*) in the dry zone of Sri Lanka and determine the dietary benefits of such behavior. Bats usually began foraging during dusk, sometimes before sunset, and also foraged during twilight in the morning. Mean use of available twilight by four radio-tagged bats was 75 percent. Twilight foraging made up, on average, 47 percent of the total foraging time of these bats (range = 25-96%), although twilight consisted of only 12 percent of the available time between sunset and sunrise the next morning. Eight species of potential predators (7 birds and 1 mammal) were observed within a 1 km radius of the colony, of which 5 species are predicted to regularly capture bats. Bats took a wide diversity of prey (11 insect orders, including at least 27 families, and spiders) that ranged in wing length from 2.0 to 54.0 mm. Major orders in the diet were Coleoptera, Lepidoptera, and Diptera. Prey of secondary importance included Hemiptera, Hymenoptera, Isoptera, and Neuroptera. Bats captured large numbers of insects that were only available or had marked peaks of abundance during twilight. These groups included small, swarming insects (especially flies) that have peaks in flight activity at dusk and dawn, large diurnal species (especially dragonflies) that have crepuscular activity, and winged termites that emerge in swarms at dusk. Access to these insects was a clear benefit of twilight foraging." (Authors)] Address: Pavey, C.R., Pk & Wildlife Commission Northern Territory, Arid Zone Research Institute, POB 1046, Alice Springs, NT 0871, Australia

2506. Perepelov, E.; Bugrov, A.G.; Warchalowska-Sliwa, E. (2001): C-banded karyotypes of some dragonfly species from Russia. II. The families Cordulegasteridae, Corduliidae and Gomphidae. *Folia Biologica, Krakow* 49(3-4): 175-178. (in English with Polish summary). ["The C-stained karyotypes of five species of three dragonfly families from Western Siberia and Kunashir Island have been analysed. *Gomphus epoptalmus*, *G. vulgatissimus*, *Nihonogomphus ruptus*, and *Anotogaster sieboldii* showed usual character of C-heterochromatin distribution, all chromosomes have terminal C-bands. *Somatochlora graeseri* has unique for dragonflies type of terminal C-blocks on autosomes. Three pairs of autosomes have the very large heterochromatic blocks, other chromosomes, including the X, have no C-band." (Authors)] Address: Perepelov, E. & A. Bugrov, Siberian Branch, Institute of Animal Systematics and Ecology, Russian Academy of Sciences, 11 Frunze St., 630091, Novosibirsk, Russia. E-mail: bugrov@fen.nsu.ru

2507. Phoenix, J.; Kneis, P.; Zinke, J. (2001): *Ophiogomphus cecilia* im sächsischen Abschnitt der Elbe (Odonata: Gomphidae). *Libellula* 20(1/2): 23-32. (in German with English summary). ["Along the River Elbe in the Free State of Saxony about one hundred individuals (larvae, exuviae, adults) of *O. cecilia* were recorded at 26 localities in the year 2000. The species settles along the whole Saxon section of the River Elbe with a length of about 180 km. The species is the most frequently recorded gomphid in this section of the River Elbe. [...]" (Authors)] Address: Phoenix, J., Goethestr. 22, D-01824 Königstein, Germany. E-mail: Juergen.Phoenix@t-online.de

2508. Piper, W.; Schrimpf, I. (2001): *Libellennachrichten*. *Libellennachrichten* 6: 1-16. (in German). [Volume 6 of the newsletter of the Society of German Speaking Odonatologists contains information on the 20th meeting held in Görlitz, the minutes of this meeting, announcements, reviews, calls for cooperation, reports of the 2001 odonatological symposia in Novosibirsk and Gällivare, "Dragonflies and new media", "Dragonflies and Literature", and "Dragonflies and Art".] Address: Schrimpf, Ilona, Heimbühlerstr. 32, D-72768 Reutlingen, Germany

2509. Plotnikova, S.I.; Sinakevich-Pean, I.E. (2001): Descending neurons of the epipharyngeal ganglion in the dragonfly *Aeshna* larva. *J. Evol. Biochem. Physiol.* 37(4): 441-443. (in English). [Using staining with methylene blue, several descending neurons were revealed in the epipharyngeal ganglion of an *Aeshna* larva. "Among them there is a neuron that has extensive arborization and unites a significant part of the epipharyngeal ganglion. The contacts of this neuron with the bundle of optic fibers from the lobule are found, which allows suggesting its participation in the descending visual pathway. A neuron of the central complex of the descending tract is revealed." (Authors)] Address: Plotnikova, S.I., Russian Acad. Sci., Sechenov Inst. Evolutionary Biochem. & Physiol., St Petersburg, Russia

2510. Radford, A.P. (2001): Repeated interception of wind blown flowers of Common Cottongrass by the Emperor Dragonfly *Anax imperator* Leach. *J. Br. Dragonfly Society* 17(2): 59. (in English). [28 June 2001, at the Waldegrave Pool, near Priddy, Somerset, UK; a strong, gusting, south-west wind carried the flowers of Common Cottongrass *Eriophorum angustifolium* "towards the pool where a male *A. imperator* was routinely patrolling over the water. As the flowers approached, the dragonfly flew towards them, into the wind. The dragonfly usually made contact with the flowers that were intercepted, although no attempt was made to seize any flowers, either by using the legs or the mouthparts. This behaviour continued, intermittently, for about five minutes, during which five or six flowers were intercepted. The individual dragonfly then resumed normal patrol activity, quite ignoring any further flowers that drifted over. There were other individuals of *A. imperator* patrolling over the pond, but none of these flew towards the airborne flowers. It was clear that only one individual was involved. Corbet (1999) mentions that Anisoptera may make investigatory flights towards large objects and then reject them when a few feet away. He states that in Florida, *Anax junius* (Drury) and *Coryphaesctma ingens* (Rambur) have been observed chasing badminton shuttlecocks. It is not clear whether these activities represent territorial defence or mistaken

prey identification." (Author)] Address: Radford, A.P., Crossways Cottage, West Bagborough, Taunton, Somerset TA4 3EG, UK.

2511. Rantala, M.J.; Hovi, M.; Korkeamaki, E.; Suhonen, J. (2001): No trade-off between the size and timing of emergence in the damselfly, *Calopteryx virgo* L.. *Ann. Zool. Fenn.* 38(2): 117-122. (in English). ["Many species of insects have been reported to show seasonally declining size at emergence. This has been explained as an adaptive response to time constraint between size and age at maturity (emergence). We studied seasonal variation in the size of damselfly *Calopteryx virgo* L. in six different creeks in central Finland. The length of hind wings was measured for 942 males and 285 females covering the flying period from mid June to mid August. The length of the hind wings of damselflies did not decrease towards the end of flying period in any river or either sex. In light of this study, seasonal reduction of body size is not a general phenomenon among odonates contrary to common understanding." (Authors)] Address: Rantala, M.J., Univ. Jyväskylä, Dept Biol. & Environm. Sci., POB 35, FIN-40351 Jyväskylä, Finland

2512. Reder, G. (2001): Späte Flugzeit von *Gomphus flavipes* am nördlichen Oberrhein (Odonata: Gomphidae). *Libellula* 20 (3/4): 175-178. (in German with English summary). [16-X-2000 and 21-X- 200, river Rhine near Nordheim, Hessen, Germany (49°42'N, 08°23'E).] Address: Reder, Gerd, Am Pfortengarten 37, D-67592 Flörsheim-Dalsheim, Germany. E-mail: PG.Reder@t-online.de

["Twenty-seven species of dragonflies are recorded from 17 localities. *Brachytron pratense* is recorded for the first time. *Cordulia aenea* has been discovered for the first time since the 1960ies. Two new localities for *Leucorrhinia rubicunda* are mentioned. *Erythromma viridulum*, *Sympetrum pedemontanum*, *S. vulgatum*, and *Anax imperator* were shown to be able to complete their development in one year." (Authors)] Address: Naumann, J., S.-Jacob-Str. 18, D-07743 Jena, Germany

2514. Rettig, K. (2001): Glänzende Smaragdlibelle (*Somatochlora metallica*). *Beitr. Vogel-Insektenwelt Ostfrieslands* 166: 19. (in German). [Germany, Lower-Saxony, LSG "Restmoor Ochtelbur", Mow; a copula of *S. metallica* was observed at 10-VII-2001.] Address: Rettig, K., Danziger Str. 11, D-26725 Emden, Germany

2515. Röhn, C. (2001): Libellen des Hepbacher-Leimbacher Rieds. *mercuriale* 1: 12-14. (in German). [This fen situated near the Lake Constance, Baden-Württemberg, Germany inhabits 40 odonate species including *Coenagrion mercuriale*, *Brachytron pratense*, *Somatochlora flavomaculata*, and *Sympetrum depressiusculum*. For more than 20 years, it harbours one of the most important populations of *S. flaveolum* in the Federal State Baden-Württemberg, Germany, [the location may be therefore considered as a core habitat of the *S. flaveolum*-population in Europe (comment of M.S.).] Address: Röhn, C., Bernried 15, D-88099 Neukirch, Germany.

2516. Rolff, J.; Vogel, C.; Poethke, H.J. (2001): Co-evolution between ectoparasites and their insect hosts: a simulation study of a damselfly-water mite interaction. *Ecol. Entomol.* 26(6): 638-645. (in English). ["1. A simulation model investigating the co-evolution of water mites infesting their aquatic insect hosts during emergence is presented. The model is based on field and experimental studies of the ectoparasitic water mite *Arrenurus cuspidator* and the damselfly *Coenagrion puella*. 2. Three scenarios were studied: (1) Only the host was allowed to evolve timing of emergence, while the timing of the parasites' infestation opportunity was held constant. (2) Both host and parasite were allowed to evolve. (3) Only the parasite's timing was allowed to evolve, while the host was constrained completely. 3. In the first two scenarios, parasite abundances decreased in the course of evolution and reached values well below, those found in the field, whereas in the third scenario parasite abundances were maintained at a level close to that found in the field. In the second scenario (co-evolution), the host seemed to be the leader in the evolutionary race. 4. It is concluded that water mite parasitism is capable of shaping emergence patterns in aquatic insects and, despite the same life-cycle length for host and parasite, the parasite evolves fast enough to shape its hatching pattern to match the emergence pattern of its host." (Authors)] Address: Rolff, J., Department of Animal and Plant Sciences, University of Sheffield, S10 2TN Sheffield, UK. E-mail: JOR@sheffield.ac.uk

2517. Rolff, J.; Braune, P.; Siva-Jothy, M.T. (2001): Ectoparasites do not affect ejaculate volume in the dragonfly *Coenagrion puella*. *Physiol. Entomol.* 26(4): 315-319. (in English). ["Imagoes of the dragonfly *C. puella* are parasitized frequently by ectoparasitic water mites. In an experimental study of the parasite load we examined the influence of parasite burden on host sperm volume. Infection with ectoparasitic water mites did not affect sperm volume in the seminal vesicle (ejaculate volume). It is concluded that water mite parasitism does not affect male fitness in *C. puella* by reducing sperm production." (Authors)] Address: Rolff, J., Department of Animal and Plant Sciences, University of Sheffield, S10 2TN Sheffield, UK. E-mail: JOR@sheffield.ac.uk

2518. Rolff, J. (2001): Effects of age and gender on immune function of dragonflies (Odonata, Lestidae) from a wild population. *Can. J. Zool.* 79(12): 2176-2180. (in English). ["Immunity is a crucial determinant of fitness. Despite this, very few studies have addressed the expression of immune function in insect populations in the wild. I present data on two immune parameters, hemocyte load and expression of phenoloxidase, in adult damselflies (*Lestes viridis*) from a wild population. In a comparison of newly emerged with sexually mature adults, it was found that the latter had higher hemocyte loads but lower phenoloxidase expression. Mature females showed significantly higher phenoloxidase expression than mature males. The sexual differences might be explained by gender differences in life history." (Author)] Address: Rolff, J., Department of Animal and Plant Sciences, University of Sheffield, S10 2TN Sheffield, UK. E-mail: JOR@sheffield.ac.uk

2519. Rolff, J. (2001): Evolutionary Ecology of water mite-insect interactions: a critical appraisal. *Archiv für Hydrobiologie* 152(3): 353-368. (in English). ["Water mites are ubiquitous parasites in freshwater ecosystems.

The interaction between water mites and aquatic insects has been scarcely studied from an evolutionary ecology viewpoint. Host finding is an important feature of the water mite's life cycle. The host finding success is suggested to depend upon host behaviour and quality. Water mite parasitism lowers host fitness via different routes: by draining nutrients hosts can suffer from decreased fecundity, increased mortality etc. Host sexes and closely related species are affected differently. Recent studies on host fitness, whilst taking the parasite behaviour into account, revealed results contrasting older studies where knowledge of the parasites' life cycle was absent. The potential for coevolution is discussed. For exploring evolutionary trends a water mite phylogeny is needed. Water mite-aquatic insect interactions can be assumed to provide excellent conditions to conduct experimental studies on direct and indirect effects of multiple natural enemies in freshwater ecosystems." (Author)] Address: Rolff, J., Department of Animal and Plant Sciences, University of Sheffield, S10 2TN Sheffield, UK. E-mail: JOR@sheffield.ac.uk

2520. Samways, M. (2001): Testing the new Categories of Threat on dragonflies in Africa. *Species* 35: 23. (in English). ["Verbatim: In a recent assessment of dragonflies across Africa and neighboring islands, it was important to distinguish between those species that are simply rare, those that are 'Data Deficient', and those that are actually threatened. The Extinct category needs very careful consideration, as premature inclusion of a species or ESU (Evolutionarily Significant Unit) could thwart further searches. In short, the IUCN 2000 Categories of Threat were found to be very workable for African dragonflies. Problems encountered were more in terms of difficulties of field assessments than with the categorization process. However, while the Red List is of great value when considering one species at a time, it should not be considered as a general database for analyzing comparative figures on assemblages. Such an analysis is likely to reveal more on assessment efforts than on the organisms themselves."] Address: Samways M.J., Invertebrate Conservation Research Centre, Dept Zool. & Entomol., University of Natal, P / Bag X01, Scottsville 3209, Pietermaritzburg, South Africa. 2521. Sasahara, S. (2001): On the status quo and conservation of *Rhyothemis severini* Ris. *Nature and Insects* 36(7): 26-28. (in Japanese). [*R. servini* was first found by me at Naze on the Amami Islands in July, 1993 and was designated as Near Threatened species in 2000. This dragonfly inhabits about ten bogs (20 to 30 cm deep) of about 50 to 500 square meters in the fallow fields, where wild millets grow. 19 sympatric species of Odonata inhabit there. The species has a weak territoriality. Males watch their mates ovipositing at the height of 1 meter from the surface of the water. They were often interfered by sympatric *R. variegata* impenetratrix. The maximum population was 30 in 1993 and in 2000 none was sighted. The main factor of decreasing is widening of a road, which caused scanty of filling water into the bogs, and pollution of water, and increasing of crayfish. This dragonfly is a newcomer to the island and preservation of it is an difficult problem. Translation; Ishizawa, Naoya] Address: not stated

2522. Saugestad, T. (2001): New observations of *Leucorrhinia pectoralis* (Charpentier, 1825) in Hordaland, western Norway. *Nord. Odonat. Soc. Newsl.* 7(1): 11.

(in Norwegian with English summary). ["A second and probable third locality in Hordaland for *L. pectoralis* was discovered 14.vii. 2000, at two small nameless bog lakes in Os municipality, near Bergen. The localities are briefly described. The probable origin of what seems to be an isolated occurrence at the west coast of Norway is also discussed." (Author)] Address: Saugestad, T., Gml. 2523. Schaijk, V.A. van; Geraeds, R.P.G. (2001): First findings of exuviae of the dragonfly *Ophiogomphus cecilia* (Fourcroy 1785) in the Netherlands. *Natuurhistorisch maandblad* 90: 166-167. (in Dutch with English summary). ["In the period of the 25th of June until the 29th of July 2001, four exuviae of *O. cecilia* were found along the river Roer. These are the first exuviae of this species found in the Netherlands. During the same inventory, two freshly emerged female adults were also spotted in the same area. These observations are the result of an intensive survey undertaken after the first sighting of this species along the river Roer last year (GERAEDS & HERMANS, 2000). The findings confirm the existence of a population of *O. cecilia* in this particular river. Further investigations in the next few years will have to show whether this species can establish itself in this area." (Author)] Address: Geraeds, R.P.G., Juliana-laan 46, NL-6042 JH Roermond, The Netherlands

2524. Schiel, F.-J. (2001): Aktuelle Daten zum Vorkommen der Asiatischen Keiljungfer (*Gomphus flavipes*) in Baden-Württemberg. *mercuriale* 1: 23-24. (in German). [Additional four localities in the Federal State Baden-Württemberg, Germany with records (exuviae) of *Stylurus flavipes* along river Rhine are dealt with.] Address: Schiel, F.-J., Inst. Naturschutz und Landschaftsanalyse, Turenweg 9, D-77880 Sasbach, Germany. E-mail: Franz-Josef.Schiel@INULA.de

2525. Schiel, F.-J.; Buchwald, R. (2001): Die Große Moosjungfer in Südwest-Deutschland. Konzeption, Durchführung und Ergebnisse des LIFE-Natur-Projekts für gefährdete Libellenarten am Beispiel von *Leucorrhinia pectoralis*. *Naturschutz und Landschaftsplanung* 33(9): 274-280. (in German with English summary). ["The LIFE-Nature project, running from 1997 to 2000, included population counts, various management measures, and extensive public information aiming to support the long-term survival of *L. pectoralis*. The survey of a total of 37 mires identified 15 populations. All of them are situated in the region "Oberschwäbisches Hügelland" (County of Ravensburg). For 11 of these populations, successful reproduction of the species has either been proven or can be considered likely. The present habitats are negatively affected by nutrient inputs and internal mineralisation. These processes lead to an accelerated growth of shore plants, and the colonised peat pools become more and more shaded by woody plants. Practical implementation of the LIFE-Nature project focused on 24 management measures undertaken in 12 different mires respectively mire areas. In four cases the removal of the dense vegetation led to a clear rise in number of observed adult dragonflies. In at least one case an increase in number of emerging individuals was shown three years after the management measures. In order to guarantee the long-term survival of *L. pectoralis* in Baden-Württemberg, management activities will remain absolutely necessary. We recommend the employment of Wildermuth's rotation model which has been successfully tested over

many years in Switzerland. Re-establishment respectively improvement of several metapopulations in the "Oberrschwäbisches Hügelland" has to be the main purpose of future management plans. In this way, a stable situation for *L. pectoralis* can be achieved, possibly also allowing recolonisation of adjacent regions." (Authors)] Address: Schiel, F.-J., Inst. Naturschutz und Landschaftsanalyse, Turenweg 9, D-77880 Sasbach, Germany. E-mail: Franz-Josef.Schiel@INULA.de

2527. Schlüpmann, M. (2001): Die Libellenfauna urbaner Lebensräume am Beispiel der Stadt Hagen. Dortmunder Beitr. Landeskunde, Naturwiss. Mitt. 35: 191-216. (in German with English summary). [The study discusses parameters responsible for suitability of water bodies in urban environments. Frequency and indiginity of species are compiled in a table. Relationships between Odonata and the degree of areas developed for buildings are discussed. The importance of garden ponds, and measures to improve their habitat quality for dragonflies is outlined. It is concluded that a urbanophilous odonate coenoses is not existing.] Address: Schlüpmann, M., Hierseier Weg 18, D-58119 Hagen, German. E-mail: martin-schluempmann@t-online.de

2528. Schmidt, B.; Osterried, J.; Stottele, T. (2001): Gewässerbericht 2000 der Stadt Friedrichshafen; Zustände, Entwicklungsziele und Maßnahmen. Schriftenreihe Umwelt der Stadt Friedrichshafen 1. 116 pp. (in German). [This is an exhaustive report on the current situation of the running waters and water management on the territory of the city of Friedrichshafen, Lake Constance, Germany. Each of the running waters is described in detail with special emphasize on restoration measures to be realised. Fauna and flora, and bordering vegetation and biotyps in the catchment area are characterised stressing indicator species and measures according environmental quality aims. Many tabs and colour pictures help to get a deep insight into the situation of the running waters of the region. Some of the material and (didactical) graphs are sound and very original. B. Schmidt is one of the leading German odonatologists, thus Odonata are well represented in this report.] Address: Stadt Friedrichshafen Amt für Umwelt und Naturschutz und Eigenbetrieb Stadtentwässerung, Postfach 2440, D-88014 Friedrichshafen, Germany

2529. Schmidt, B. (2001): Habitate, Fortpflanzungsverhalten und Eiablagestrategien der Südlichen Mosaikjungfer (*Aeshna affinis*) im Eriskircher Ried (Bodensee). *mercuriale* 1: 14-18. (in German). [Probably since more than 10 years, an autochthonous population of the Mediterranean species *A. affinis*, which currently extends its range to the north, exists in the Eriskirchener Ried (fen situated near Lake Constance, Baden-Württemberg, Germany). The author documents all records of the species in this locality, supposing that the initial establishment of the species

establishment of the species may be the result of influxes in 1987 (or 1992 and 1995). In 1999 *A. affinis* was the most common member of Aeshnidae in the Eriskircher Ried! The climatic preferred situation of the locality is in addition documented by a strong population of *Lestes barbarus*. The author describes the habitat, hunting and searching flights for females, and oviposition sites in detail. He discusses the possibility of different oviposition strategies of the two colour morphs of females (brown/light blue and brown/yellow green): the light blue colour morph seems to oviposit without male in more densely grown habitats, while the yellow green morph seems to oviposit in tandem position with male in more open, shallow waters. Advantage and disadvantage of the strategies on the population level are discussed.] Address: Schmidt, B., Sandöschstr. 28; D-88048 Friedrichshafen, Germany. E-mail: Schmidt-empire@gmx.de

2530. Schmidt, Eb. (2001): Strittige systematische Fragen auf Gattungsniveau bei mitteleuropäischen Libellen (Odonata). Abh. Ber. Naturkundemus. Görlitz 73 (1): (in German with English summary). ["The following genera (including European species) can be separated by autapomorphies: *Chalcolestes* Kennedy, 1920, from *Lestes* Leach, 1815, with *C. viridis* (Vander Linden, 1825); *Stylurus* Needham, 1897, from *Gomphus* Leach, 1815, with *S. flavipes* (Charpentier, 1825); *Platetrum* Newman, 1833, from *Libellula* L., 1758, with *P. depressum* (L., 1758); *Ladona* Needham, 1897, from *Libellula* too, with *L. fulva* (Müller, 1764). *Aeshna isocoetes* (Müller, 1767) should not yet be transferred into the (palaetropical) genus *Anaciaeschna* Selys, 1878. *Tarnetrum* Needham & Fisher, 1936 is now accepted on subgenus level only for *Sympetrum* (*Tarnetrum*) *fonscolombii* (Selys, 1840). The genera *Cercion* and *Erythromma*, *Anax* and *Hemianax* should still remain separated for the European species." 2532. Schultz, J.K.; Switzer, P.V. (2001): Pursuit of heterospecific targets by territorial Amberwing Dragonflies (*Perithemis tenera* Say): A case of mistaken identity. *Journal of Insect Behavior* 14(5): 607-620. (in English). ["Although they are defending mating territories, territory residents of a wide variety of insect species have been observed to pursue heterospecifics in addition to the conspecifics that intrude on their territories. One species that has such heterospecific pursuits is" *Perithemis tenera* "In this study, we tested five alternative hypotheses for the function of heterospecific pursuits in amberwings: competition for resources, preven-

tion of interference while mating, predator deterrence, foraging, and mistaken identity. Resident males pursued both male and female conspecifics, as well as a species of horse fly (*Tabanus* spp.) and butterfly (*Ancyloxypha numitor*). Other intruding odonates, including *Epitheca princeps*, *Erythemis simplicicollis*, *Libellula luctuosa*, *Pachydiplax longipennis*, and *Plathemis lydia*, were relatively ignored. Because the horse fly and butterfly were similar to amberwings in body size, color, and flight height, and because they are not predators or prey of amberwings, we concluded that the pursuit of these heterospecifics was due to mistaken identity. The characteristics of the horsefly and butterfly likely correspond to the cues that the male amberwings use to identify conspecifics, and the relative rarity of intrusions by these two species (as well as by female amberwings) probably made it more costly to discriminate and pursue only conspecifics than to make some mistaken pursuits." [Documentation of some mailings circulated to members of the SGL with notes on records of *Coenagrion scitulum* in Vorarlberg, Austria, a new record of *Ophiogomphus cecilia*, some sneering comments on the myth of sticking dragonflies (the myth is assessed as unthreatened in the Red list of myths), notes on the comming meeting of SGL and GdO, and the minutes of the founding meeting of SGL and the constitution of this organisation.] Address: SGL c/o Röske, W., Kandelstr. 26, D-79106 Freiburg, Germany

2534. Sherratt, T.N.; Forbes, M.R. (2001): Sexual differences in coloration of Coenagrionid damselflies (Odonata): a case of intraspecific aposematism? *Anim. Behav.* 62(4): 653-660. (in English). ["Sexual dimorphism is commonly explained as a consequence of selection on traits that increase male attractiveness to females, or simply allow males greater access to females. Here, we consider another explanation for sexual differences in coloration within species of the damselfly family Coenagrionidae (Odonata: Zygoptera). In many of these species, males are more brightly coloured than females and have different patterns. Yet they are non-territorial and do not engage in displays: indeed, male competition for mates often resembles a scramble. We therefore argue that even if females show a degree of mate choice, then it is unlikely to be based on colour or pattern. Instead, we suggest that sexual dimorphism has evolved in this group primarily as a form of sex-related warning coloration. First, we argue that it is almost inevitable that male-male interactions will incur a small cost to both participants. We then provide some evidence that males are capable of using colour as a clue to sexual identity. Using a simple model, we show that if these conditions hold, then sexual dimorphism will readily evolve. Furthermore, the model shows that if females are selected to avoid excessive harassment by males as is often suggested, then males should evolve much brighter coloration than females. If the assumptions underlying our 'unprofitable mate' model are broadly correct, then not only does it offer a novel explanation for sexual dimorphism, but it also provides the first case example of the evolution of aposematism as a result of intraspecific interactions." (Authors)] Address: Sherratt

2535. Showers, J.; Horsnail, P. (2001): Damselfly exuviae found in a UV light moth trap. *J. Br. Dragonfly Society* 17(2): 33-34. (in English). ["Damselflies were first noted in the trap on 31 May 2000, and were then found on each day until 12 June 2000. A total of 187 exuviae were collected during this period, with a maximum total of 56 collected on 1 June. After 12 June, only occasional exuviae were found and these were not identified. In addition to the exuviae found inside the light trap, many exuviae were present on the supports, but these were not collected. The emerged damselflies either found their own way out of the trap or were released when the trap was checked for moths." A total of 105 exuviae of *Enallagma cyathigerum* and three *Erythromma najas* exuviae were identified. "It was not possible to identify all specimens, as many were badly damaged." [...] "The discovery of large numbers of damselfly exuviae in the moth trap suggests that damselfly larvae may be attracted to UV light at emergence. This observation supports previous work indicating a response to UV light by emerging larvae of the family Coenagrionidae (Lavoie-Dornik & Pilon, 1987). It also poses several areas for further investigations, including the variation in response between species, the most effective wavelengths for eliciting a response, and the relationship between the intensity of the light source and the distances over which damselfly larvae will be attracted." (Authors)] Address: Showers, J., B., Desborough Road, Rothwell, Kettering, Northants NN14 6JQ, UK

Pictures of *Erythromma najas* and *Somatochlora arctica* illustrate the odonatological importance of the area. For more odonatological details see: Ott, J. (1990): Die Libellenfauna des geplanten Naturschutzgebietes "Gelterswoog - Kolbenwoog" - mit einem Wiederfund von *Somatochlora arctica* Zetterstedt für Rheinland-Pfalz. *Fauna Flora Rheinland-Pfalz* 6: 227-246.] Address: Struktur- und Genehmigungsdirektion Süd, Neustadt an der Weinstraße

2545. Swaay, C. van; Ketelaar, R.; Groenendijk, D. (2001): Dagvlinders en libellen onder de meetlat: jaaverslag 2000. Rapport VS2001.07. De Vlinderstichting Wageningen: 29 pp. (in Dutch with English summary). [This is a report on the monitoring scheme of butterflies and dragonflies in The Netherlands in 2000. The butterfly scheme started in 1990, the dragonfly scheme in

1997. Butterflies and dragonflies are counted using a line-transect method. Dragonfly transects are visited once every two weeks. "The length of the transects is variable and dependent on habitat quality and availability. In addition, single species transects are exclusively counted for a specific threatened butterfly or dragonfly. Thus, more information is obtained on trends of our Red List species. Indices were calculated using the computer program TRIM (Trends and Indices for Monitoring Schemes). This program was developed by CBS ("Statistics Netherlands") for the analysis of time series of counts with missing observations." 185 Odonata-transects were visited every fortnight and 133 single species plots were counted. "Although the number of transects is still growing, in the southern provinces more plots are needed for reliable indices. *Enallagma cyathigerum* was again by far the most numerous dragonfly species in 2000. At the most species-rich plots 25 species were recorded. Special results from the monitoring scheme include for example: (1) *Calopteryx virgo* was counted at 8 transects in 2000. A total of more than 1600 individuals was recorded. At one wooded lowland river densities were much higher than in any other river system in The Netherlands. *C. virgo* is now satisfactorily covered within the monitoring scheme. (2) *Aeshna viridis* is one of the best followed species within the dragonfly monitoring scheme. At a total of 14 transects 185 dragonflies were counted. (3) In the city of Gouda much more dragonflies (both diversity and the number of individuals) were counted at transects alongside ecologically restored banks in the city than in non-restored localities." Address: De Vlinderstichting, Postbus 506, NL-6700 AM Wageningen, The Netherlands. E-mail: info@vlinderstichting.nl

2546. Szállassy, N.; Bárdosi, E.; Szabó, Z.; Dévai, G. (2001): Fluctuating asymmetry and mating success in males of *Libellula fulva* Müller, 1764. *Abh. Ber. Naturkundemus. Görlitz* 73(1): 91-92. (in English with German summary). [In this study, individually marked *Libellula fulva* males were used to compare short-term and medium-term methods on the basis of correlating wing asymmetry with mating success.] Address: Devai, G., Department of Ecology, Kossuth L. 2554. Utzeri, C. (2001): Winter oviposition of *Sympetrum striolatum* (Charp.) in central Italy (Anisoptera: Libellulidae). *Notul. odonatol.* 5(8): 106-107. (in English). [In January 2000 and 2001 *Sympetrum* sp. were observed in Italy. "The present record suggests, therefore, that at least at the central Italian latitudes, the yearly extinction of the *S. striolatum* adult population in late autumn is probably caused by long periods of bad weather, including drop of temperature, which preclude dragonfly activity and feeding. If ambient conditions keep relatively good and stable, dragonflies can probably go on with feeding and egg maturation, and perform normal reproductive behaviour, including mating and oviposition." (Author)] Address: Utzeri, C., Dipartimento di Biologia Animale e dell'Uomo, Università di Roma "La Sapienza". Viale dell'Università 32, 1-00185 Roma, Italy. E-mail: carlo.utzeri@uniroma1.it

2555. Van Gossum, H.; Stoks, R.; De Bruyn, L. (2001): Frequency-dependent male mate harassment and intra-specific variation in its avoidance by females of the damselfly *Ischnura elegans*. *Behav. Ecol. Sociobiol.* 51: 69-75. (in English). ["We focused on male harassment on different female color morphs of the damselfly *Ischnura elegans* and on variation in morph-specific mating avoidance tactics by females. In *I. elegans*, one of the female morphs is colored like the conspecific male (andromorphs) while the other morphs are not (gynomorphs). Our first goal was to quantify morph-specific male mating attempts, hence male harassment, in populations with manipulated population parameters (densities, sex ratios, and proportion of andromorphs). Second, we examined the female's perspective by looking for potential differences in morph-specific mating avoidance tactics and success of those tactics in a natural population. Differences in population conditions did influence the number of male mating attempts per morph. The less frequent female morph was always subject to fewer mating attempts, which contradicts earlier hypotheses on mimicry, but supports those that assume that males learn to recognize female morphs. Gynomorphs occupy less open habitat and often fly away when a male approaches, while andromorphs use more open habitat, do not fly large distances and directly face approaching males. Female morphs did not differ in the proportion of successful mating-avoidance attempts. Our results suggest that the maintenance of the color polymorphism is most probably the result of interactive selective forces depending on variation in all population conditions, instead of solely density- or frequency-dependent selection within populations." 2556. Vanappelghem, C.; Veille, F. (2001): Observations de *Leucorrhinia rubicunda* (L., 1758) dans le Nord-Pas-de-Calais en 2000 (Odonata, Anisoptera, Libellulidae). *Martinia* 17(3): 91-94. (in French with English summary). [Two male adults of *L. rubicunda* were captured 15 May 2000. The habitat is described, and the existence of local populations is discussed, but it may be likely that the species has (dis)migrated from Belgium.] Address: Veille, F., Office National des Forêts, 19 avenue du General de Gaulle, F-62600 Berck, France

2557. Vizslán, T.; Huber, A. (2001): Odonate records from sub-Carpathia, southwestern Ukraine. *Notul. odonatol.* 5(8): 103-105. (in English). [Records of 24 odonate species from 21 localities in the area of the rivers Latorcyja and Uz are presented. The list includes *Coenagrion pulchellum*, *Erythromma viridulum*, and *Soma-tochlora metallica*] Address: Vizslán, T., Szent Mihály út 9., H-9400 Sopron, Hungary

2558. Wallaschek, M. (2001): Zur Insekten- und Herpetofauna (Odonata, Dermaptera, Blattoptera, Saltatoria: Ensifera et Caelifera, Amphibia, Reptilia) von Trocken- und Feuchtgebieten im Landkreis Eichsfeld (Thüringen). *Thüringer faunistische Abhandlungen* 8: 7-36. (in German with English summary). [22 odonate species from 7 sampling localities are documented and briefly discussed. *Lestes dryas*, *L. virens*, *Sympetma fusca*, *Ischnura pumilio*, *Sympetrum flaveolum*, and *Leucorrhinia rubicunda* are of some regional interest.] Address: Wallaschek, M., Agnes-Gosche-Str. 43, D-06120 Halle (Saale), Germany

2559. Weatherhead, M.A.; James, M.R. (2001): Distribution of macroinvertebrates in relation to physical and biological variables in the littoral zone of nine New Zealand lakes. *Hydrobiologia* 462: 115-129. (in English). ["[...] there have been few attempts to relate macroinvertebrates to habitat factors in lakes. In this study, nine mainly oligotrophic lakes from throughout New Zealand were surveyed for macroinvertebrates. The lakes were selected to represent a range of suspended sediment loading and lake level regimes. Within each lake, several sites were selected to provide a range of exposure to wave action. A multiple regression approach was taken to relate macroinvertebrate community composition and habitat characteristics. The results of the analysis suggest that the littoral zone of the lakes we studied could be divided into four general habitats. The first is the wave wash zone characterised by coarse substrates and macroinvertebrate taxa usually associated with lotic environments, such as Ephemeroptera and Plecoptera. The second habitat is associated with macrophytes and is limited at the top by wave action and at depth by light attenuation. In this zone, the snail *Potamopyrgus antipodarum* is dominant, along with Trichoptera and Odonata. At the base of the macrophytes is the detrital habitat characterised by fine, organic rich sediments and dominated by chironomids, oligochaetes and Trichoptera. At depths below the macrophyte zone, fine sediments are found, and bivalves such as the freshwater mussel *Hyridella menziesi* are common. While macroinvertebrate abundance can be highly variable, some general predictions of community structure can be made based on a few key environmental factors. Abundance of snails, Odonata and Trichoptera was positively related to macrophyte biomass. Some macroinvertebrate groups such as oligochaetes, chironomids, snails and bivalves were more common in line substrates, while Ephemeroptera were characteristic of coarse substrates. Detrital biomass was important for most of the macroinvertebrate groups studied showing a positive relationship for oligochaetes and Trichoptera and a negative relationship for Ephemeroptera and Plecoptera." (Authors)] Address: Weatherhead, M.A., Natl Inst Water & Atmospher Res Ltd, POB 8602, Christchurch, New Zealand

2560. Weihrauch, F. (2001): Entwicklung von *Onychogomphus f. forcipatus* in einem Kleingewässer (Odonata)

ta: Gomphidae). *Libellula* 20 (3/4): 149-154. (in German with English summary). ["From May 21 to June 02 2001, 175 exuviae of *O. f. forcipatus* were collected at a shallow gravel pond with a size of almost 300 m² in Munich, Bavaria, Germany. This is the first record of the successful development of the species in waters of that kind. Besides, this is the hitherto earliest seasonal record of *O. f. forcipatus* from Bavaria." (Author)] Address: Weihrauch, F., Hengelerstr. 9, D-80637 München, Germany. E-mail: Florian.Weihrauch@t-online.de

2561. Weipert, J.; Bößneck, U. (2001): Die Schutzgebiete der Landeshauptstadt Erfurt (Thüringen) Teil IV: Flora und Fauna des GLB "Dorfstattwiese". Veröff. Naturkundemus. Erfurt 20: 57-80. (in German with English summary). [Thuringia, Germany; in 1995, five common odonate species were recorded.] Address: Bößneck, U., Stadtverwaltung Erfurt, Umwelt- und Naturschutzamt, Staffenbergallee 18, D-99085 Erfurt, Germany

2562. Werzinger, S.; Werzinger, J. (2001): Ganz schön flexibel! Zur Entwicklung von *Anax parthenope* in Bayern (Odonata: Aeshnidae). *Libellula* 20(3/4): 131-148. (in German with English summary). ["A Bavarian larval generation of *A. parthenope* developed bivoltin as well as univoltin. At an unused fish-free pond we recorded 244 exuviae - 226 (92,6 %) during the autumn in 1998 and 18 (7,4 %) during the following spring in 1999. The pond was located in an area of about 400 km², the so-called Florisches Weihergebiet, about 40 km northwest of Nuremberg. *A. parthenope* is well known here for several decades, but there have been no breeding records so far. Since 1998 we observed increasing occurrences of imagines, especially in springtime. In spite of the successful development in 1998 and 1999 it is still unknown where the breeding generations normally origin. Larval development and emergence of *A. parthenope* are discussed." (Authors)] Address: Werzinger, S., Düsseldorfer Str. 15, D-90425 Nürnberg, Germany. E-mail: Werzinger-Nbg@t-online.de

2563. Wildermuth, H.; Bauer, S. (2001): Das Wurzelgeflecht schwimmender Seggenstöcke als Mikrohabitat von Libellenlarven (Odonata). *Libellula* 20(1/2): 33-45. (in German with English summary). ["Larvae of 4 Zygoptera and 4 Anisoptera species were found among roots and in cavities of floating sedge (*Carex elata*, *C. paniculata*) tussocks of two small moorland lakes in southern Germany. *Cordulia aenea* was the most numerous species, followed by *Platycnemis pennipes*, *Erythromma najas*, *Somatochlora metallica*, *Aeshna grandis* and *Epitheca bimaculata*. Prior to the emergence period of the «spring species», a single tussock harboured at least 1 and 46 larvae at most (43 *C. aenea*) on a probing day. Final stage larvae of *C. aenea* amounted up to 77% of a day total. The root system of sedge tussocks at steep lake and pond shores otherwise poor in structure turned out to be an important microhabitat for dragonfly larvae, especially during the final stage, as well as for many other benthic animal species. Measures for conservation and promotion of the structural diversity at the shores of stagnant waters are discussed." (Authors)] Address: Wildermuth, H., Haltbergstr. 43, CH-8630 Rüti, Switzerland. E-mail: hansruedi@wildermuth.ch

Westd. Entomol. Tag 2000*: 287-290. (in German). [The development of knowledge of the distribution of *S. fusca* and *G. vulgatissimus* in the Federal State Nordrhein-Westfalen, Germany is briefly outlined. *S. fusca* could be observed in 12.8% of all grid squares. In most cases records refer to single specimens, only few strong populations are existing. Records of *G. vulgatissimus* increased in the past years significantly.] Address: Willigalla, C., Brock 45, D-48346 Ostbevern, Germany. E-mail: christoph@willigalla.de

2569. Wong, A.; Forbes, M.R.; Smith, M.L. (2001): Characterization of AFLP markers in damselflies: prevalence of codominant markers and implications for population genetic applications. *Genome* 44(4): 677-684. (in English). ["Amplified fragment length polymorphism (AFLP) analysis is becoming increasingly popular as a method for generating molecular markers for population genetic applications. For practical considerations, it is generally assumed in population studies that AFLPs segregate as dominant markers, i.e., that present and absent are the only possible states of a given locus. We tested the assumption of dominance in natural popula-

tions of the damselfly *Nehalennia irene* [...]. Electroblotted AFLP products from 21 samples were probed with individual markers. Eleven markers were analyzed, of which two were monomorphic and nine were polymorphic. Only two of the polymorphic markers behaved in a strictly dominant manner. The remaining seven polymorphic markers displayed various degrees of codominance, with 2-10 visible alleles in the sample. Of the three markers displaying the highest degree of variability, two contained microsatellite repeat tracts. Our results suggest that the assumption of dominance is unfounded. As a result, AFLP analysis may be unsuitable for estimating several important population genetic parameters, including genetic diversity." 2573. Zimmermann, W. (2001): Rote Liste der Libellen (Odonata) Thüringens. 3. Fassung, Stand 10/2001. Naturschutzreport 18: 76-79. (in German). [Red list of endangered Odonata from Thuringia, Germany. 52 of the 61 Thuringian Odonata are autochthonous, 32 species are redlisted. Compared with the second version of the list (Zimmermann & Mey, 1993) *Calopteryx splendens*, *Coenagrion hastulatum*, and *Aeshna grandis* could be deleted from the list due to improvement of knowledge or increasing populations. *Leucorrhinia dubia* and *Erythromma najas* had to be added due to decline of populations, and *Coenagrion ornatum*, *Gomphus vulgatissimus*, *Thecagaster bidentata*, and *Leucorrhinia albifrons* have been (re-)discovered in recent years.] Address: Zimmermann, W., Thomas-Müntzer-Str. 5, D-99423 Weimar, Germany

2002

2574. Andrew, R.J. (2002): Egg chorionic ultrastructure of the dragonfly *Tramea virginia* (Rambur) (Anisoptera: Libellulidae). *Odonatologica* 31(2): 171-175. (in English). ["SEM studies reveal that the egg chorion of *T. virginia* is divided into an outer soft exochorion and an inner tough endochorion. The exochorion expands into a jelly-like, sticky coat in water, while the endochorion is smooth, thin and unsculptured. The apically situated micropylar apparatus is formed of a large, dome-shaped, sperm-storage chamber and a small, flat, micropylar stalk which contains a pair of circular micropylar orifices. The micropylar apparatus is encircled by an exochorionic collar. The chorion is modified in accordance with the aquatic (still-water) mode of oviposition exhibited by this species while the micropylar apparatus is shaped to fit in the fertilization pore of the vagina." (Author)] Address: Andrew, R.J., Department of Zoology, Shri Shivaji ESA's Science College, Congress Nagar, Nagpur - 440012 (MS), India

2575. Bede, L.C.; Machado, A.B.M.; Piper, W. (2002): *Erythrodiplax venusta* (Kirby), an Amazonian species introduced into Minas Gerais, SE Brazil (Anisoptera: Libellulidae). *Notul. odonatol.* 5(9): 113-114. (in English). [The distribution of *E. venusta* encompasses the Amazonian parts of Venezuela, Surinam, Guiana, Bolivia, Peru and northern to western Brazil. The compilation of Borror (1942) and the examination of the Machado-collection with material from all Brazilian states showed *E. venusta* to be restricted to the Amazonian region, thus not belonging to the fauna of Minas Gerais, a state that has been intensively collected for about 50 years. It was surprising therefore, that on February 26 and April 9, 1994, 5 male *E. venusta* were collected at the Sumidouro lake (municipalities of Pedro Leopoldo & Lagoa Santa, Minas Gerais, southeast Brazil, 19°32'05"S; 43°56'28"W), a locality situated as far as 1300 km from the hitherto known southernmost range of this species, in Mato Grosso. The locality was surveyed formerly by Machado in March 1975. At that time, no *E. venusta* was sighted. The authors conclude, that these circumstances indicate that this species has been introduced into the area not too long ago, and the question raised as to how it was transported there. The possibility that *E. venusta* was brought to the Lagoa Santa region by some atmospheric phenomenon, involving wind transportation, cannot be ruled out. However, in 1984 a modern airport was built in the area (Confins Internatio-

nal Airport, ca 20 km from the Sumidouro lake) and started receiving regular cargo from the northern cities, like Manaus and Belem, where *E. venusta* occurs. Therefore it is probable that the species may have been incidentally introduced into the area by aircraft. The Confins Airport frequently receives ornamental and game fish from the Amazon region, bringing the possibility of eventual introduction of dragonfly eggs or larvae into the Lagoa Santa karst system.] Address: Bede, L.C., Laboratorio de Ecologia e Comportamento de Insetos, Departamento de Biologia Geral, ICB/UFMG, C.P. 486, BR-31270-901 Belo Horizonte, MG, Brazil

2576. Belle, J. (2002): Commented checklist of the Odonata of Surinam. *Odonatologica* 31(1): 1-8. (in English). ["A list is given of 283 spp. and sspp., referable to 87 genera of 15 families. Some additional taxa are evidenced but remain unidentified. Notes are supplied on some spp. *Hetaerina cruentata*, *Argia extranea*, *Phyllocycla signata*, *Phyllogomphoides audax*, *Dythemis sterilis*, *D. velox*, *Erythrodiplax attenuata*, *E. ochracea*, *E. aequatorialis*, and *Perithemis waltheri* are deleted from the national list." (Author)] Address: Belle, J., Onder Beumkes 35, NL-6883 HC Velp, The Netherlands

2577. Bernard, R. (2002): First records of *Aeshna crenata* Hagen, 1856 in Lithuania with selected aspects of its biology (Odonata: Aeshnidae). *Opusc. zool. flumin.* 202: 1-21. (in English). [The six Lithuanian records of *A. crenata* have significantly broadened the known range of the species to the southwest. Its habitat - wind sheltered, mostly Shagnum-rich lakes - is characterized in detail. The size of individuals and the thoracic pattern are briefly described. Some aspects of the emergence are presented. The behaviour of territorial males and ovipositing females is described in great detail. The co-existence with other aeshnids is briefly analysed, with reference to spatial segregation between *A. crenata* and *A. juncea* / *A. subarctica elisabethae*. The 6 localities are described in detail and the co-occurring odonate species are listed, among them *Nehalennia speciosa*, *Epithea bimaculata*, *Leucorrhinia albifrons*, and *L. caudalis*.] Address: Bernard, R., Dept of General Zoology, Adam Mickiewicz University, Fredry 10, PL-61-702 Poznan, Poland; E-mail: rbernard@main.amu.edu.pl

2578. Beukema, J.J. (2002): Changing distribution patterns along a stream in adults of *Calopteryx haemorrhoidalis* (Odonata: Calopterygidae): a case of larval-drift compensation? *International Journal of Odonatology* 5(1): 1-14. (in English). ["The distribution of an isolated population of adult *C. haemorrhoidalis* was studied along a small stream in NE Spain, during two-week or three-week summer periods over five years. Distribution patterns differed consistently between age groups. Reproductive activities took place along the entire stream, whereas the presence of teneral and older immature individuals was restricted to the lower reaches of the stream. It is concluded that emergence took place only in the lower reaches and that this can be explained by larval drift due to strong currents regularly depleting the upper half of the stream. Recovery of individually marked teneral specimens indicated that immature individuals remained in the area around the lower reaches, during roughly the first week of their adult life. During the following week, when they had attained mature wing coloration but did not yet show reproductive activities, they moved for long distances.

This was particularly true for newly matured males, where the distance between two successive encounters could amount to hundreds of meters. By far the greatest proportion of these moves was upstream. Movement in later life stages, i.e. during the reproductive part of their life, was infrequent, much shorter and less consistently directed, though generally more often upstream than downstream. Once the males defended a territory, they hardly moved anymore. Territories were spread more evenly along the stream at high rather than at low overall densities. It is concluded that territorial behaviour contributed to a more even distribution of mature males and that an inborn tendency to fly upstream is not a prerequisite for the observed upstream-biased dispersal during adult life." (Author)] Address: Beukema, J.J., Netherlands Institute for Sea Research, P.O. Box 59, NL-1790 AB Den Burg, Texel, The Netherlands. E-mail: janb@nioz.nl

2579. Beukema, J.J. (2002): Survival rates, site fidelity and homing ability in territorial *Calopteryx haemorrhoidalis* (Vander Linden) (Zygoptera : Calopterygidae). *Odonatologica* 31(1): 9-22. (in English). ["In a small isolated population along a small stream in NE Spain, a high proportion of the adults present were individually marked. During subsequent days, their locations were assessed by twice-daily surveys along the entire length of the stream. Mean daily survival rates in mature males and females and pre-reproductive males were similar, 94%. Only during the first day after marking were survival rates significantly lower (viz. 77 to 84% in the various groups). High proportions (around 90%) of mature males were found to return to the same (territory) site every morning once they had occupied that site for 2 or more days. Site fidelity was low in pre-reproductive males and intermediate in mature females. In a displacement experiment, 67 territorial males were transferred one by one to distant locations (80 to 240 m along the stream). Half of them returned to their original territory, usually on the same day." 2586. Buskirk, J., van (2002): Phenotypic lability and the evolution of predator-induced plasticity in tadpoles. *Evolution* 56(2): 361-370. (in English). ["The hypothesis that predator-induced defenses in anuran larvae are maintained by divergent selection across multiple predation environments has not been fully supported by empirical results. One reason may be that traits that respond slowly to environmental variation experience a fitness cost not incorporated in the standard adaptive model, due to a time lag between detecting the state of the environment and expressing the phenotypic response. I measured the rate at which behavior and morphology of *Rana temporaria* tadpoles change when confronted with a switch in the predation environment at two points in development. Hatchling tadpoles that had been exposed during the egg stage to *Aeshna* dragonfly larvae were not phenotypically different from those exposed as eggs to predator-free conditions, and both responded similarly to post-hatching predator treatments. When 25-day-old tadpoles from treatments with and without dragonflies were subjected to a switch in the environment, their activity budgets reversed completely within 24-36 h, and their body and tail shape began changing significantly within 4 days. The behavioral response was conservative: Tadpoles switched from high-risk to predator-free treatments were slower to adjust their activity. The study confirmed that behavioral traits are relatively labile and exhibit strong plasticity, but it did not reveal such a pattern at the level of individual traits: Morphological traits that developed slowly did not show the least plasticity. Thus, I found that differences in lability of traits here useful for predicting the magnitude of plasticity only for fundamentally different kinds of characters." (2002): Bewertung des ökologischen Zustandes eines Donaualtarmes ("Alte Donau") in Wien aus libellenkundlicher Sicht (Insecta: Odonata). *Lauterbornia* 44: 83-97. (in German with English summary). ["The ecological status of a Danubian backwater (Old Danube) situated in Vienna (Austria) was assessed by a dragonfly survey. 8 field trips were conducted at 9 sites (shore length = 100 m). A total of 20 species was recorded, 17 of them autochthonous. In this study a new assessment procedure based on the Odonate Habitat Index ("OHI") was applied. The range of site-specific index values was very close (2.49-3.05) with the mean OHI being 2.81. These numbers indicate a low level of habitat diversity. The comparison of the status quo with a reference condition is the basis of the assessment of the ecological status according to the EU Water Framework Directive. According to this the ecological status of the Old Danube was ranked as class III ("moderate ecological status") in the 5-tiered classification scheme. Missing littoral habitat structures and the lack of hydrological dynamics are the main reasons for this result." - 2595.** Corbet, P.S. (2002): Stadia and growth ratios of Odonata: a review. *International Journal of Odonatology* 5(1): 45-73. (in English). ["A terminology is presented for structures and events in larval development of Odonata with the aim of bringing terms into conformity with those used for other insect orders in the light of accepted views of homology. The terms 'exuvia', 'larva', 'prolarva' and 'stadium' receive special mention. Records of the number of stadia required to complete larval development for 118 species are listed and analysed, showing that the range for Odonata is 8 through 18 stadia (8 through 18 for 8 species of Anisoptera; 8 through 17 for 38 species of Zygoptera) averaging 12.4 stadia for the order (Anisoptera 12.5 and Zygoptera 12.2), in which >90% of records range from 10 through 16 stadia (both Anisoptera and Zygoptera >90%). The number of stadia varies between and within species,

sometimes within members arising from a single egg batch. No unifying hypothesis exists to rationalize variation in the number of stadia. Duration of successive stadia within a species can be a smooth, increasing progression but can also show wide departures from such a pattern. Duration of a single stadium can range from 1 day (or <1 day in the prolarva) through >1 year. Uniformity of size of the final-stadium larva can be achieved by the growth ratio (between successive ecdyses) compensating for the number of stadia. Aeshnidae typically have more stadia than do Libellulidae and also have a smaller average growth ratio. Ontogenetic profiles of growth ratios for different dimensions tend to have a characteristic form for each dimension, regardless of the eventual number of stadia. For some dimensions (e.g. headwidth) and some species the profile forms a smooth declining progression but for others (e.g. length of caudal appendage) it fluctuates irregularly. Headwidth therefore represents the dimension of choice for specifying stages of larval development. Rewarding avenues for research include the documentation of prospective links between larval life style on the one hand and stadal numbers and growth-ratio profiles on the other, and discovery of morphological characters that make it possible to determine to species larvae of early stadia." 2596. Cordero Rivera, A.; Egido Perez; F.J.; Andres, A. (2002): The effect of handling damage, mobility, body size, and fluctuating asymmetry on lifetime mating success of *Ischnura graellsii* (Rambur) (Zygoptera: Coenagrionidae). *Odonatologica* 31(2): 117-128. (in English). ["Several species of odonates have been the subject of sexual selection studies. In non-territorial species most variance in lifetime mating success (LMS) is accounted for by lifespan and specially by the number of visits, and random factors (like rainy weather) can have strong effect on reproductive success. Here we present the study of 2 natural populations of *I. graellsii* by marking-recapture methods. Our results show that male mating success is related to body size, mobility and handling damage, but not to fluctuating asymmetry. Larger males had greater success in both populations, a result in agreement with previous findings on the same sp. Nevertheless, multivariate analyses indicate that body length was a significant correlate of LMS in just one of the studied populations. We estimated a mobility index for males averaging the distance between consecutive resightings. For long-lived males, we found a positive relationship between mobility and LMS. There was a clear effect of leg loss during marking on survivorship, and a marginally significant negative effect on LMS. Finally, we studied the effect of wing fluctuating asymmetry (FA) on LMS by capturing a sample of marked individuals at the end of field work. Results suggest that FA is not an important correlate of LMS in this sp." (Authors)] Address: Cordero Rivera, A., Departamento de Ecología e Biología Animal, Universidade de Vigo, E.U.E.T. 2597. Covanec, A.; Schiemer, F.; Waidbacher, H.; Spolwind, R. (2002): Rehabilitation of a heavily modified river section of the Danube in Vienna (Austria): Biological assessment of landscape linkages on different scales. *Internat. Rev. Hydrobiol.* 87: 183-195. (in German with English summary). ["The ecological condition

of the Danube section in Vienna (Austria) has been greatly impaired by urban development, regulation, channel straightening and the construction of a hydroelectric power plant. In 1997, the shoreline of the Danube in this area was restructured by artificial side channels, coves, gravel banks, pools and temporary waters. A monitoring programme has been established focusing on the investigation of the functional integrity of these inshore structures: first results show that the sites isolated from the Danube serve as stepping stone biotopes for dragonflies and amphibians. Particularly amphibians are suitable indicators of the ecological functioning of riparian migration linkages on a (macro-) habitat scale. Rheophilic fish species (e.g. *Chondrostoma nasus*) colonise side channels connected with the Danube and indicate a longitudinal connectivity on a landscape scale. The role of these structures within an urban greenway is discussed." (Authors) Fig. 2 demonstrates succession of odonate fauna at different newly created inshore zone each for the successive years 1998 and 1999.] Address: Chovanec, A., c/o Umweltbundesamt, Spittelauer Lände 5, A-1090 Wien, Austria. 2600. De Marco, P.; Resende, D.C. (2002): Activity patterns and thermoregulation in a tropical dragonfly assemblage. *Odonatologica* 31(2): 129-138. (in English). ["Solar exposure is a key factor determining odonate activity, particularly in tropical areas. Small sized perchers, classified as thermal conformers, can begin their activity when air temperature is sufficiently high, and larger species become active when direct exposure to the sun is possible. In this study, the activity patterns in a neotropical dragonfly assemblage present on the Federal University of Viçosa, SE Brazil, have been described and following predictions about their thermoregulatory behaviour tested: (a) a decrease in activity of the percher dragonflies in the warmest peri-

ods is expected due to high thoracic temperatures; (b) conformers species will be controlled by temperature, not luminosity, whereas in heliothermic species, the initiation and termination of their activity is only constrained by luminosity. In the dry season, low air temperatures represent a limiting factor to the beginning and the end of activity, resulting in a shorter total activity time. *Orthemis discolor* and *Micrathyria hesperis* showed a decrease in activity in the middle of the day in the rainy season. *Perithemis mooma* was the only species that had a higher abundance near midday. As this species had a light-coloured thorax compared to the others, it is suggested that it could minimize the effect of the high temperatures. There is a clear effect of season on activity time, and also large differences in the intensity of this effect among species. When clouds precluded direct exposure to sun, variations only in the temperature did not affect the activity of *Erythrodiplax fusca*, *M. hesperis*, and *O. discolor*, but the activity of the small sized *P. mooma* remained dependent on temperature. These results highlighted that the minimum body size to be a heliotherm could be a complex function of behavioural and morphological characteristics, including body colour, preferred substrate and perch posture." 2604. Fleck, G.; Nel, A.; Bechly, G.; Escuillite, F. (2002): The larvae of the mesozoic family aeschniidae and their phylogenetic implications (Insecta, Odonata, Anisoptera). *Paleontology* 45(1): 165-184. (in English). ["Four giant dragonfly larvae are described from the Lower Cretaceous of China. Owing to the preservation of wing tracheal venation on the larval wing sheaths, they can be identified as the first undoubted larvae of the extinct Mesozoic family Aeschniidae. They are ultimate or penultimate male and female specimens, and a younger larva. The female larva has a very long ovipositor sheath. These larvae have an anisopteran anal pyramid and a very particular spoon-shaped labial mask, with a very narrow prementum and large palps with numerous teeth, suggesting possible affinities of the Aeschniidae with the Anisoptera Cavilabiata. The positions of other larvae formally attributed to the Aeschniidae are discussed, i.e. *Nothomacromia sensibilis* (Carle and Wighton, 1990), *Sona nectes* Pritykina, 1986, and the alleged larvae of *Hemeroscopus baissicus* Pritykina, 1977. They differ greatly from the true Chinese larval Aeschniidae, in the labial mask and female ovipositor, even if they show some similarities in the anal pyramid." (Authors)] Address: Fleck, G., Lab. 2610. Hecker, K.R.; Forbes, M.R.; Leonard, N.J. (2002): Parasitism of damselflies (*Enallagma boreale*) by gregarines: sex biases and relations to adult survivorship. *Can. J. Zool.* 80(1): 162-168. (in English with French summary). ["We studied host damselflies *E. boreale* [...] and their gregarine parasites (Apicomplexa: Eugregarinidae) to elucidate the causes and consequences of any sex biases in parasitism of adult hosts. Larvae of both sexes were highly infected, but there was no difference between male and female larvae in either prevalence or intensity of gregarine infections. Newly emerged adults had few or no parasites, thereby setting the stage for investigating accumulation of parasites by adults. Adult females had a higher prevalence and intensity of infection by gregarines than did males, but only on 1 (of 2) days when the potential confounding factor of host age was controlled for. Both adult males and females showed a positive correlation between longevity under conditions of food stress and the number of gregarines they initially carried. This finding may be explained if the food ingested with the infective cysts is more beneficial than the parasites are harmful, and it also has implications for investigating sex biases in numbers of trophically transmitted parasites of such insects." 2611. Heino, J. (2002): Concordance of species richness patterns among multiple freshwater taxa: a regional perspective. *Biodivers. Conserv.* 11(1): 137-147. (in English). ["Geographical gradients in species richness and the degree to which different taxa show congruent patterns remain unknown for many taxonomic groups. Here, I examined broad-scale species richness patterns in five groups of freshwater organisms; macrophytes, dragonflies, stoneflies, aquatic beetles and fishes. The analyses were based on provincial distribution records in Denmark, Norway, Sweden and Finland. In general, variation in species richness across provinces was concordant among the groups, but stoneflies showed weaker negative relationships with the other taxonomic groups. Species richness in most groups decreased with increasing latitude and altitude, and a considerable part of the variation was explained by mean July temperature. However, stoneflies showed a reversed pattern, with species richness correlating positively, albeit more weakly, with mean provincial altitude. Nevertheless, combined species richness of all five taxa showed a strong relationship with mean July temperature, accounting for 74% of variation in provincial species richness alone. Such temperature-controlled patterns suggest that regional freshwater biodiversity will strongly respond to climate change, with repercussions for local community organization in freshwater ecosystems in Fennoscandia." 2612. Hoshide, K.; Janovy, J. (2002): The structure of the nucleus of *Odonaticola polyhamatus* (Gregarinea: Actinocephalidae), a parasite of *Mnais strigata* (Hagen) (Odonata: Calopterygidae). *Acta Protozool.* 41(1): 17-22. (in English). ["The nucleus of *Odonaticola polyhamatus* was isolated from the body and observed with light, scanning electron and transmission electron microscopy. The nucleus had a thick thread-like structure with which it was tied to the septum. This thread-like structure has not been reported or described previously. The gregarine nuclear surface was covered with a fine fibrous net. This is the first report of the surface structure of a gregarine nucleus as revealed by SEM. Inside the nuclear membrane was a thin honeycomb layer similar to that reported for some other gregarines. Several spherical nucleoli and numerous electron dense small structures were observed inside the nucleus." (Author)] Address: Hoshide, K., Yamaguchi Univ., Inst. Biol., Fac. Educ., Yamaguchi 7538513, Japan

2615. Jenkins, R.K.B; Ormerod, S.J. (2002): Habitat preferences of breeding water rail *Rallus aquaticus*. *Bird Study* 49(1): 2-10. (in English). ["[...] To test a survey method for estimating the abundance of breeding Water Rail and to provide an assessment of coarse-scale habitat selection, Water Rails were surveyed in 1996-97 at 77 wetland sites across Wales using broadcast vocalizations from a handheld cassette player. [...] Basic habitat characteristics were recorded for all sites and more detailed information, including freshwater invertebrate samples, were taken from a subset of 22 sites. A minimum of 43 to 49 breeding pairs of Water Rail were counted. Numbers of individuals differed significantly between the two survey years, but estimates of the number of pairs were consistent. Water Rail occurrence at a site was significantly related to the presence of wet reed *Phragmites* sp. Dry sites with low vegetation cover were the least occupied. Water Rail abundance was positively correlated with the abundance of Odonata, Plecoptera and Diptera larvae, but lack of data on actual dietary composition prohibits concluding a causal relationship. We hypothesize that increased Water Rail abundance associated with expanses of wet reed reflects a combination of nest safety, reduced risk of predation, and increased food availability. Current reed-bed management to maintain wetland conditions, often standard procedures for such systems, are probably beneficial to Water Rail." 2616. Johansson, F.; Wahlström, E. (2002): Induced morphological defence: evidence from whole-lake manipulation experiments. *Can. J. Zool.* 80(2): 199-206. (in English). ["Predator-induced defences are activated by cues associated with predators and confer some degree of resistance to subsequent attacks. Laboratory studies of many taxa have revealed such induced defences, and these data often conform to large-scale surveys of defence levels in habitats with and without predators. However, there have been no studies that make the direct connection between these laboratory studies and field surveys. We conducted a large-scale field manipulation of predators to provide this connection. Previous laboratory experiments on dragonfly (*Leucorrhinia dubia*) larvae have demonstrated that the presence of fish predators induces the development of elongated abdominal spines that serve to reduce mortality risk. In this study we determine the effect of whole-lake predator manipulation on this induced morphological defence of *L. dubia*. We monitored the spine lengths of final-instar larvae in two experimental lakes for 7 consecutive years. Fish were present during the first 2 years and then removed for the remaining 5 years. Results demonstrate that the spine lengths of *L. dubia* larvae decreased significantly in both lakes after the removal of fish. In contrast, there was no corresponding change in the spine lengths of larvae in reference lakes, and we found little change in food supply for larvae. Our results suggest that the plastic response in spine length is strong and attributable to the presence of predators." 2619. Kotiaho, J.S.; Hovi, M. (2002): Correcting species richness hotspots for latitudinal gradients: a new method. *Ann. Zool. Fenn.* 39(1): 3-6. (in English). ["Species richness hotspots are of critical importance in conserving biodiversity, but by using simple species richness in an area, there is an inevitable bias in favour of lower latitudes. We propose a simple method for estimating regionally representative species richness hotspots where the effect of latitudinal gradients is accounted for. By using this method, the same number of species are conserved but instead of being concentrated on lower latitudes the selected areas fall into much larger geographical regions resulting in a broader range of habitat types conserved. This method suits any scale and is also applicable to other kinds of environmental gradients. These regions are illustrated with data on birds and dragonflies of Finland." (Author)] Address: Kotiaho, J.S., Univ. Jyväskylä, Dept Biol. & Environm. Sci., POB 35, FIN-40351 Jyväskylä, Finland

2620. Legrand, J. (2002): Un nouveau *Tragogomphus* d'Afrique équatoriale: *T. ellioti* spec. nov. (Anisoptera: Gomphidae). *Odonatologica* 31(2): 193-197. (in French with English summary). ["The new species is described and illustrated from a single male, collected in Gabon. Holotype male: Eastern Gabon, Makokou area, 1-XI-1976; deposited in MNHN, Paris. It lives in the upper sections of forest streams. The new sp. seems to be close to *T. aurivillii* Sjöstedt, 1899, but it is very different from the sympatric *T. tenaculatus* (Fraser, 1926), known from this region." (Author)] Address: Legrand, J., 10, rue du Chemin de fer, F-94110 Arcueil, France

2621. Long, R. (2002): Southern Skimmer *Orthetrum brunneum* (Fonsc.) on Guernsey. *Atropos* 15: 10. (in English). 2628. Matushkina, N.; Gorb, S. (2002): Stylus of the odonate endophytic ovipositor: a mechanosensory organ controlling egg positioning. *J. Insect Physiol.* 48(2): 213-219. (in English). ["Using light and scanning electron microscopy, a sensory field consisting of 15-20 campaniform sensillae is described on the base of the stylus of the endophytic ovipositor of Odonata. It is hypothesised that two symmetric styli equipped with this number of sensillae can function as a mechanosensory organ responsible for control of precise egg positioning in plant stems during oviposition. In laboratory experiments with females of damselflies *Lestes sponsa* and *L. barbarus*, it was demonstrated that the distance between laid eggs is not dependent on the presence of styli. Removal of styli from both sides did not influence a shift of oviposition to one side. Females with one removed stylus shifted the clutch line in the opposite direction toward the removed stylus. Additionally, removal of styli influenced positions of single eggs in egg sets, and disturbed the capacity for complex oviposition. Thus, both morphological and experimental data support the hypothesis that styli participate in the control of egg line and egg patterning in the clutch." 2629. Melnychuk, M.C.; Srivastava, D.S. (2002): Abundance and vertical distribution of a bromeliad-dwelling zygopteran larva, *Mecistogaster modesta*, in a Costa Rican rainforest (Odonata: Pseudostigmatidae). *International Journal of Odonatology* 5(1): 81-97. (in English). ["We compared the larval abundance of *M. modesta* between bromeliads at ground level and canopy level in a primary tropical wet forest. Zygopteran abundance correlated strongly with bromeliad diameter at both levels. Although the per-bromeliad zygopteran abundance did not differ between vertical levels, *M. modesta* showed a strong vertical distribution in abundance owing to the variation in bromeliad size and density along a vertical gradient, with more and larger bromeliads closer to ground level than to the canopy. We predict *M. modesta* larval abundance to be 171 ± 65

(s.e.) per hectare, with >80% of larvae below halfway to the lower canopy limit. The total prey abundance or species richness did not differ between ground and canopy bromeliads, further suggesting that apart from bromeliad size, habitat quality for *M. modesta* was similar between vertical levels. Effects of habitat size on larval abundance patterns are addressed by comparing habitat volume and basal resource mass with diameter. Finally, larger-scale spatial patterns in zygopteran abundance are discussed with reference to bromeliad distributions." (Authors)] Address: Melnychuk, M. & Diane S. Srivastava, Dept of Zoology, University of British Columbia, 6270 University Boulevard, Vancouver, B.C., Canada V6T 1Z4. E-mail: srivast@zoology.ubc.ca

2630. Minelli, A. (2002): Homology, limbs, and genitalia. *Evolution & Development* 4(2): 127-132. (in English). ["Similarities in genetic control between the main body axis and its appendages have been generally explained in terms of genetic co-option. In particular, arthropod and vertebrate appendages have been explained to invoke a common ancestor already provided with patterned body outgrowths or independent recruitment in limb patterning of genes or genetic cassettes originally used for purposes other than axis patterning. An alternative explanation is that body appendages, including genitalia, are evolutionarily divergent duplicates (paramorphs) of the main body axis. However, are all metazoan limbs and genitalia homologous? The concept of body appendages as paramorphs of the main body axis eliminates the requirement for the last common ancestor of limb-bearing animals to have been provided with limbs. Moreover, the possibility for an animal to express complex organs ectopically demonstrates that positional and special homology may be ontogenetically and evolutionarily uncoupled. To assess the homology of animal genitalia, we need to take into account three different sets of mechanisms, all contributing to their positional and/or special homology and respectively involved (1) in the patterning of the main body axis, (2) in axis duplication, followed by limb patterning mechanisms diverging away from those still patterning the main body axis (axis paramorphism), and (3) in controlling the specification of sexual/genital features, which often, but not necessarily, come into play by modifying already developed and patterned body appendages. This analysis demonstrates that a combinatorial approach to homology helps disentangling phylogenetic and ontogenetic layers of homology." (Author) *Drosophila* and *Odonata* are studied.] Address: Minelli, A., Univ Padua, Dept Biol, Via Ugo Bassi 58B, I-35131 Padua, Italy

2631. Novelo-Gutiérrez, R. (2002): Larvae of the ophibolus-species group of *Erpetogomphus* Hagen in Selys from Mexico and central America (Anisoptera: Gomphidae). *Odonatologica* 31(1): 35-46. (in English). ["Detailed descriptions and illustrations of *Erpetogomphus* *agkistrodon* Garrison, *E. erici* Novelo and *E. ophibolus* Calvert are provided and a comparison with other larvae of the subgenus *Erpetocyclops* Carle is also included. Larvae of *E. agkistrodon* and *E. erici* show the closest resemblance, while *E. ophibolus* is more similar to *E. constrictor*." (Author) In addition *Erpetogomphus* *sabaleticus* Williamson 1918 and *E. tristani* Calvert 1912 are described without figures.] Address: Novelo-Gutiérrez, R., Departamento de Entomología, Instituto de Ecología A.C., Km 2.5. antigua carretera a

2633. Oertli, B.; Auderset Joye, D.; Castella, E.; Juge, R.; Cambin, D.; Lachavanne, J.-B. (2002): Does size matter? The relationship between pond area and biodiversity. *Biological Conservation* 104: 59-70. (in English). ["Larger areas support more species. To test the application of this biogeographic principle to ponds, we consider the relationship between size and diversity for 80 ponds in Switzerland, using richness (number of species) and conservation value (score for all species present, according to their degree of rarity) of aquatic plants, molluscs (Gastropoda, Sphaeriidae), Coleoptera, Odonata (adults) and Amphibia. Pond size was found to be important only for Odonata and explained 31% of the variability of their species richness. Pond size showed only a feeble relationship with the species richness of all other groups, particularly the Coleoptera and Amphibia. The weakness of this relationship was also indicated by the low z-values obtained (< 0.13). The SLOSS analyses showed that a set of ponds of small size has more species and has a higher conservation value than a single large pond of the same total area. But we also show that large ponds harbour species missing in the smaller ponds. Finally, we conclude that in a global conservation policy (protection, restoration, management), all size ranges of ponds should be promoted." (Authors) 0-24 odonate species, in mean 8,4 species, occurred at the ponds.] Address: Oertli, B., Laboratoire d'Ecologie et de Biologie Aquatique, University of Geneva, IS chemin des Clochettes, CH-1206 Geneva, Switzerland. 2636. Peacor, S.D. (2002): Positive effect of predators on prey growth rate through induced modifications of prey behaviour. *Ecology Letters* 5(1): 77-85. (in English). ["Many prey modify behaviour in response to predation risk and this modification frequently leads to a foraging rate reduction. Although this reduction can have a clear direct negative effect on prey growth rate, theory predicts that a net positive effect can occur when the combined reduction in foraging by the entire population leads to a large increase in resource level. Here, I present experimental results that corroborate this counterintuitive prediction: the predation threat of 'nonlethal' caged larval dragonflies (*Anax longipes*) caused a net increase in small bullfrog (*Rana catesbeiana*) growth. *A. longipes* caused a net increase in small bullfrog be-

havioural response (i.e. a reduction in activity, level and microhabitat usage) was likely to have negatively affected growth, but was offset by a positive effect of growth from a large increase in resource levels (measured using a bioassay). Further, the positive *Anax* effect was dependent on nutrient level, illustrating the role of the resource response magnitude. Results of this study are discussed in the context of studies in which *Anax* had the opposite (i.e. negative) effect on tadpole growth. Predator-induced modifications in prey behaviour can have large negative or positive effects on prey growth, the sign and magnitude of which are dependent on relative species density, and resource dynamics." 2638. Purse, B.V.; Thompson, D.J. (2002): Voltinism and larval growth pattern in *Coenagrion mercuriale* (Odonata : Coenagrionidae) at its northern range margin. *Eur. J. Entomol.* 99(1): 11-18. (in English). ["Voltinism and larval growth pattern were investigated in an edge-of-range population of *C. mercuriale*. *C. mercuriale* is semi-voltine in Britain and growth is inhibited in winter. The 2nd year group overwinters in a range of instars between the antepenultimate and final instar consistent with the early, asynchronous emergence pattern of this species. A facultative autumnal diapause in the penultimate instar is the most likely mode of seasonal regulation. The broad size distribution of larvae produced by this growth pattern was wider than that found in co-occurring populations of *Pyrrhosoma nymphula*, a "spring" species with synchronous emergence. The broad size distributions may lead to considerable intraspecific interference between *C. mercuriale* larvae. Sex ratio in the last three larval instars of *C. mercuriale* did not differ significantly from unity. A laboratory investigation of the effect of temperature and photoperiod on growth and diapause in *C. mercuriale* is recommended to determine whether high minimum temperature thresholds for development limit both the width of the temporal niche and microhabitat use by this species at its range margin." (Authors)] Address: Purse, B.V., Univ Liverpool, Populat & Evolutionary Biol Res Grp, Sch Biol Sci, Nicholson Bldg, POB 147, Liverpool L69 3GS, Merseyside, UK

[This bibliography is a real treasure trove for anybody looking for the regional literature on Saxonian entomofauna. The titles are organised alpha-numerical, and according to five regions ("Planungsregionen") and in-

sect orders. The bibliography includes published and unpublished literature, e.g. management plans or expertises. Odonatological literature is easy to trace from this bibliography. It is planned to edit an electronic version of the bibliography in the beginning of 2003. Orders should be directed to the address below.] Address: Reinhardt, R., Burgstädter Str. 80a, D-09648 Mittheida, Germany. E-mail: Reinhardt-Mittw@t-online.de

2640. Relyea, R.A. (2002): Costs of phenotypic plasticity. *American Naturalist* 159(3): 272-282. (in English). ["Phenotypically plastic organisms display alternative phenotypes in different environments. It is widely appreciated that possessing alternative phenotypes can affect fitness. However, some investigators have suggested that simply carrying the ability to be plastic could also affect fitness. Evolutionary models suggest that high costs of plasticity could constrain the evolution of optimal phenotypes. However, costs (and limits) of plasticity are primarily hypothetical. Little empirical evidence exists to show that increased plasticity leads to reduced growth and development, leads to increased developmental instability, or limits the ability of organisms to produce more extreme phenotypes. I used half-sib families of larval wood frogs (*Rana sylvatica*) reared in outdoor mesocosms to examine how tadpoles altered behavioral, morphological, and life-historical traits in response to larval dragonfly predators (*Anax longipes*). The predators induced lower activity and the development of relatively large tails and small bodies in wood frogs. As a result, wood frogs experienced reduced growth and development. I then examined whether tadpole sibships with higher plasticity experienced fitness costs (above and beyond the costs of expressing a particular phenotype) and whether they were limited in producing extreme phenotypes. Fitness effects of plasticity were widespread. Depending on the trait examined and the environment experienced, increased plasticity had either positive effects, negative effects, or no effects on tadpole mass, development, and survivorship. I found no relationship between increased plasticity and greater developmental instability. There was also no evidence that sibships with increased plasticity produced less extreme phenotypes; the most extreme trait states were always produced by the most plastic genotypes. This work suggests that costs of plasticity may be pervasive in nature and may substantially impact the evolution of optimal phenotypes in organisms that live in heterogeneous environments." 2641. rtr (2002): Kunstinsekten für den Mars. die tagzeitung, Freitag, 25. Januar 2002: 14. [Verbatim: "SYDNEY rtr Über die Oberfläche des Mars könnten bald winzige Flugzeuge mit der Gewandtheit von Libellen und dem Sehvermögen von Bienen schwirren. Wissenschaftler in Australien haben eigenen Angaben zufolge die Sinnesorgane verschiedener Insektenarten imitiert und neuartige Navigations- und Fluggeräte entwickelt. Die neuen Sensoren seien so klein, dass sie auf "Microflyers" mit einem Gewicht von 75 Gramm Platz fänden, sagten die Forscher der Australian National University (ANU). Trotz ihrer kleinen Gehirne können Insekten wie Libellen schnelle und präzise Manöver fliegen, die Flugstabilität und Kollisionsvermeidung voraussetzen", sagte Javaan Singh Chahl von der ANU. Die diesem Prinzip nachentwickelte Technologie

könnte seinen Angaben zufolge 2007 bei einer Mission eingesetzt werden, bei der die Felsstruktur des Val-les Marineris auf dem Mars erkundet werden soll. Das Modell der Wissenschaftler ist den Facettenaugen von Insekten nachempfunden. Nach Aussagen der Forscher könnten die Kunstinsekten auch in der äußerst dünnen Atmosphäre des Mars stabil und kontrolliert navigiert werden."]

2642. Samways, M. (2002): Red-listed Odonata of Africa. *Odonatologica* 31(2): 151-170. (in English). ["The Red-Listed African Odonata species are re-assessed and are assigned or re-assigned to the IUCN Categories of Threat. It is important to distinguish between those species that are simply rare, those that are 'Data Deficient' and those that are genuinely threatened. It is also important to consider the 'Extinct' category very carefully as premature inclusion of a taxon in this category can preclude further searches for it. The IUCN Categories of Threat were found to be very workable for the African Odonata. Problems are more to do with the practicalities of doing the field assessments, rather than with the categorisation itself. While the Red List is of enormous value when considering one species at a time, it should not be seen as a generalized data base amenable to comparative assemblage statistics, which are likely to reveal more on assessment efforts than on the organisms." 2643. Schütte, C.; Schrimpf, I. (2002): Explaining species distribution in running water systems: larval respiration and growth of two Calopteryx species (Odonata, Zygoptera). *Archiv für Hydrobiologie* 153(2): 217-229. (in German with English summary). ["*C. virgo* is most often encountered at running water rhitron, whereas *C. splendens* predominantly chooses the hyporhitron to metapotamon. Larval growth of both species was studied in two streams in the field and under three different temperatures in the laboratory (12 °C / 18 °C / 24 °C). Their respiration was tested at the same three temperatures by measuring the CO₂-production of the larvae via gas chromatography. At low temperatures, *C. virgo* was growing faster and had a higher standard metabolism than *C. splendens*. While *C. splendens* had similar respiration rates at 12 °C, 18 °C and 24 °C, the respiration of *C. virgo* was significantly higher at lower temperatures, as it is adapted to cold environments. But additionally, *C. virgo* is outspeeding *C. splendens* in growth even at 24 °C, suggesting that besides temperature adaptation there have to be other factors hindering co-occurrence of both species in warm streams." 2648. Tembhare, D.B.; Wazalwar, S.M. (2002): Stomodaeal cuticular structures in the dragonfly *Brachythemis contaminata* (Fabricius) (Anisoptera : Libellulidae). *Odonatologica* 31(1): 47-54. (in English). ["Light and scanning electron microscopic studies reveal various stomodaeal cuticular structures. In the larvae and adults, microspines on the surface of the longitudinal folds of the pharynx, and dome-shaped, beaded structures on the inner surface of the oesophagus are evident. In the larvae, the folds of the crop bear long hairs laterally and parallel rows of microspines medially. In the larvae, the proventriculus is provided with 4 longitudinal plates; 2 large plates with teeth on each lateral side and 2 small plates each with 4 fine apical teeth, on either side. Scale-like acanthae are observed near the stomodaeal valve. A whorl of long hairs is evident in the stomodaeal valve. In the adult dragonfly, the acanthae and curved spines occupy the anterior and posterior regions of the proventricular dental plates, respectively. The functional significance of various stomodaeal cuticular structures is discussed." (Author)] Address: Tembhare, D.B., Dept Zool., Nagpur Univ. Campus, Nagpur 440010, Maharashtra, India

2649. Tennessen, K.J. (2002): *Argia rosleri* sp. nov. from central Bolivia (Odonata: Coenagrionidae). *International Journal of Odonatology* 5(1): 99-104. (in English). ["*Argia rosleri* sp. nov. is described from central Bolivia. Holotype male: Santa Cruz Department, Florida Province, seep along Rio Achira, 8.6 km E of Samaipata (18°09'42"S, 63°48'53"W), 1,400 m a.s.l., 25 xi 1999; allotype female: same locality, 05 xi 1998; both leg. K.J. Tennessen. The new species appears to be related to the *A. gerhardi/nigrior* complex, but differs in being mostly pale and having the decumbent ventral tooth of the male cerci apically situated." (Author)] Address: Tennessen, K., 1949 Hickory Ave. Florence, AL 35630, USA. E-mail: ktennessen@aol.com

2650. Tennessen, K.J. (2002): *Telebasis simulata* spec. nov. from South America, previously confused with *T. sanguinalis* Calvert (Zygoptera: Coenagrionidae). *Odonatologica* 31(2): 205-210. (in English). ["The new species (holotype male, allotype female: Brazil, State of Amazonas, Manaus, 20-V-1-1922; deposited in FSCA, Gainesville, Fla, USA) is described and illustrated based on 82 males and 15 females from Brazil, Surinam, Trinidad and Venezuela. It most closely resembles *T. sanguinalis* but differs mainly by: (1) translucent dorsal flap of terminal penile segment rectangular in lateral view, gradually tapered to posterior lateral

angle (vs flap with a posterolateral lobe-like extension directed posteriorly); (2) cerci 1.6 to 1.8 times as long as paraprocts (vs 2.0 times as long); (3) rear of head half black, black marking extending to occipital foramen (vs pale except for a pair of small, dark circular spots). *T. sanguinalis* is known only from central Bolivia and western Brazil." (Author)] Address: Tennesen, K., 1949 Hickory Ave. Florence, AL 35630, USA. E-mail: ktennesen@aol.com

2651. Trembath, R.; Anholt, B.R. (2002): Predator-induced morphological and behavioral changes in a temporary pool vertebrate. *Israel Jour. Zool.* 47(4): 419-431. (in English). ["Temporary pools vary unpredictably in their complement of predators, which should select for inducible anti-predator defenses. Temporary pools are used by many amphibians during the larval stage. We raised larvae of a hylid frog, *Hyla versicolor*, in the presence and absence of their predator, the larval dragonfly *Anax junius*. Tadpoles raised in the presence of predators were less active, more variable in size, and had larger, more brightly colored tails than those raised in the absence of predators. We found that acceleration from a motionless start was related to tail morphology. Similar to previous studies, our data suggested that tadpoles raised in the presence of predators were less vulnerable than those raised in the absence of predators, although our results were not statistically significant. The stochastic nature of oviposition into temporary pools argues that their biota will be variable in space and time. We expect that temporary pool specialists will often show inducible phenotypes for anti-predator defenses." 2655. Williams, P.; Whitfield, M.; Biggs, J.; Fox, G.; Nicolet, P.; Shillabeer, N.; Sherratt, T.; Heneghan, P.; Jepson, P.; Maund, S. (2002): How realistic are outdoor microcosms? A comparison of the biota of microcosms

and natural ponds. *Environ. Toxicol. Chem.* 21(1): 143-150. (in English). ["This study investigated the extent to which aquatic plant and macroinvertebrate assemblages in small outdoor microcosms (cylinders 1.25 m diameter x 1.25 m deep) resembled assemblages found in natural ponds in Britain. Comparisons were made in terms of community structure, species richness, and numbers of uncommon species. Multivariate analysis indicated that, although the microcosms had no exact natural analogues, their plant and animal assemblages were most like those of deep, circumneutral ponds. Unlike natural ponds, the microcosms supported relatively species-poor invertebrate assemblages, lacking uncommon species. Among individual taxa, microcosms supported similar numbers of species of Gastropoda, Isopoda, Amphipoda, and Odonata as natural ponds but significantly fewer Coleoptera, Hemiptera, and Trichoptera species. This was most likely due to the absence of a shallow littoral area in the microcosms. Because of their vertical sides, the microcosms supported no marginal wetland plants, but submerged and floating-leaved plant assemblages were similar in community type and species richness to natural ponds. Refinements to microcosm and mesocosm designs are identified that would enable experimental systems to more closely replicate the assemblages found in natural ponds. In particular, the incorporation of natural margins would be likely to lead to experimental communities that were closer analogues of natural ponds." 2658. Yourth, C.P.; Forbes, M.R.; Smith, B.P. (2002): Immune expression in a damselfly is related to time of season, not to fluctuating asymmetry or host size. *Ecol. Entomol.* 27(1): 123-128. (in English). ["Variation in immune responsiveness within and among species is the subject of the emerging field of ecological immunology. The work reported here showed that individuals of *Lestes forcipatus* Rambur differ in their likelihood of mounting immune responses, and in the magnitude of those responses, against a generalist ectoparasite, the water mite *Arrenurus planus* Marshall. 2. Immune responses took the form of melanotic encapsulation of mite feeding tubes, occurred in the few days after host emergence, and resulted in mites dying without engorging. Such immune responses were more probable and stronger for hosts sampled later rather than earlier in the season. Such responses may act as selection affecting seasonal patterns of egg hatching and larval abundance of mites. 3. Contrary to expectation, metrics of host size (wing length) and wing cell fluctuating asym-

metry were not related to the likelihood of immune responses. 4. The importance of season on immune expression of insects has not been explored in detail. These results suggest possible trade-offs in allocation of melanin (or its precursors) to maturation versus immunity and indicate the need for studies on the synergistic effects of weather and parasitism on host species that use melanotic encapsulation to combat parasites and pathogens." (in Jap., with English summary (English translation of Naoya Ishizawa in Digest of Japanese odonatological Short Communications 7, 1998)). ["The reproductive behaviour was studied at a small pond in Shiura village, Kita-gun. Aomori pref., N Japan, from May to Aug. 1996. Hibernated adults appeared at the pond from mid May, and a few adults remained until early August. Reproductive behaviour was observed on fine and warm days from late May to mid July (peak during the first half of June). Male seized the female without courtship and display, immediately after he found her. Sperm transfer ($x=60.8$ s) was carried out just after the tandem was formed at a perching site. Copulation was observed between 7:30 and 14:30 h with the peak from 9:00 to 10:00 h and it was divided into 3 stages; the characteristic pumping was seen at each stage. Copulation lasted 15 min 47 s on average (stage 1: 14 min, 42 s, I: 93.4 s. III: 10.3 s). Sperm displacement was recognized by comparing the volumes of 9s sperm storage organ collected at precopula, copula and postcopula. Tandem oviposition took place soon after copulation in the leaves of *Phragmites communis*, above the water, during 8:00-16:00 h, with the peak from 10:00 to 12:00 h; interspecific tandem was recorded in 3 cases." 2679. Wisenden, B.D.; Chivers, D.P.; Smith, J.F. (1997): Learned recognition of predation risk by *Enallagma* damselfly larvae (Odonata, Zygoptera) on the basis of chemical cues. *Journal of Chemical Ecology* 23(1) : 137-151. (in English). ["We studied two populations of damselfly larvae (*Enallagma boreale*): one popu-

lation cooccurred with a predatory fish (northern pike, *Esox lucius*); the other did not. Damselflies that cooccurred with pike adopted antipredator behavior (reduced activity) in response to chemical stimuli from injured conspecifics, and to chemical stimuli from pike, relative to a distilled water control. Damselflies from an area where pike do not occur responded only to chemical stimuli from injured conspecifics. In a second set of experiments, we conditioned pike-naive damselflies to recognize and respond to chemical stimuli from pike with antipredator behavior. Damselfly larvae that were previously unresponsive to pike stimuli learned to recognize pike stimuli after a single exposure to stimuli from pike and injured damselflies or pike and injured fathead minnows (*Pimephales promelas*). The response to injured fathead minnows was not a general response to injured fish because damselfly larvae did not respond to chemical stimuli from injured swordtails (*Xiphophorus helleri*), an allopatric fish. Taken together, these data suggest a flexible learning program that allows damselfly larvae to rapidly acquire the ability to recognize local predation risk based on chemical stimuli from predators, conspecifics, and heterospecific members of their prey guild." (Authors)] Address: Wisenden, B.D., Department of Biology, University of Saskatchewan 112 Science Place, Saskatoon, Saskatchewan, Canada, S7N 5E2, Canada

2680. Wudkevich, K.; Wisenden, B.D.; Chivers, D.P.; Smith, J.F. (1997): Reactions of *Gammarus lacustris* to chemical stimuli from natural predators and injured conspecifics. *Journal of Chemical Ecology* 23(4) : 1163-1171. (in English). ["We exposed the freshwater amphipod *G. lacustris*, to chemical stimuli from injured conspecifics and to chemical stimuli from two types of natural predators: dragonfly larvae (*Aeshna eremita*) and northern pike (*Esox Indus*). Exposure to all three stimuli caused *G. lacustris* to reduce significantly its level of activity relative to activity recorded in response to a distilled water control. The similarity in responses to chemicals associated with predators and to injured conspecifics suggests the presence of an alarm pheromone within the body tissues of *G. lacustris*. In response to chemical stimuli from pike, *G. lacustris* tended to reduce its time in the water column and spend more time near the bottom of the test aquaria. However, no such trend was apparent in response to chemical stimuli from dragonfly larvae. The differences in response to chemical stimuli from pike and larval dragonflies suggest that *G. lacustris* does not have a rigid behavioral response to predation risk; instead, antipredator behavior may be modified to maximize avoidance of predators that are active in different microhabitats." Universität Bremen: 102 pp, Anhang 35 pp. (in German). [A published abridged version of this M. Sc. thesis is abstracted in OAS 2408. The thesis provides a lot of additional information, e.g. distribution maps, graphs of the sampling localities, detailed species lists, and species monographs. The focus of the thesis is set on the efficiency and efforts of measures made to compensate impacts on landscape and habitats from the odonatological point of view. Each of these measures is assessed in detail. Of some interest is the description of the success of ditch management with special emphasize of species preferring *Stratiotes aloides* (*Aeshna viridis*, *Anaciaeschna isosceles*). In general, the study provides interesting material on the design of compensation measures for Odonata.] Address: Adena, Julia, Geibelstr. 61, D-28215 Bremen, Germany

- 2696.** Rampazzi, F. (1998): Le libellule (Insecta: Odonata) delle torbiere a sfagni del cantone Ticino e del Moesano (Val Calanca e Val Mesolcina, GR), Svizzera. *Boll. Soc. ticin. Sci. not.* 86(2): 19-28. (in Italian, with English summary). [During the period 1990-1993 the Odonata of 20 peat-bogs of the Canton Ticino and Moesano (Calanca and Mesolcina, GR, Switzerland) were surveyed. The study sites are situated in the southern Swiss Alps (Ticino, Grisons) at altitudes between 275 and 2020 m a.s.l. 25 species of dragonflies were recorded, 18 of which are reproducing in at least one of the 20 investigated sites, but only *Aeshna caerulea*, *A. juncea*, *Somatochlora alpestris*, *S. arctica*, *Libellula quadrimaculata*, *Sympetrum danae*, and *Leucorrhinia dubia* show clear preferences for peat-bog habitats. The occurrence of peat-bog species depends particularly on temperature, water acidity and structure of aquatic habitats. The most characteristic species are represen-

ted by *S. arctica* and *A. caerulea* (only in peat-bogs above 1700 m a.s.l.) and particularly by *L. dubia*, which occurs only in peat-bogs with dystrophic ponds. In the study-area *A. caerulea* and *L. dubia* are very rare species (only 3 sites), while *A. juncea* and *S. alpestris* show the higher frequency among the investigated dragonflies-communities (12-14 sites). However, the affinity of *A. juncea* and *S. alpestris* with peat-bog habitats decrease strongly by increasing altitude, and in the subalpin region they become more or less eurytopic. The likewise "tyrphobiontic species" such as *Coenagrion hastulatum* or *L. pectoralis*, which are both present in the northern part of Switzerland and of Italy, could not be found.] Address: Rampazzi, F., Mus. cantonale Stor. nat., Viale Cattaneo 4, CH-6900 Lugano, Switzerland.

2697. Tennessen, K. (1998): Ecuador IV - we learn some more. *Argia* 9(4): 13-15. (in English). [Report of a collecting trip to the eastern slopes of Ecuador.] Address: Tennessen, K., 1949 Hickory Ave. Florence, AL 35630, USA. E-mail: ktennessen@aol.com

2698. Utzeri, C.; Cordero, A., Santolamazza Carbone, S.; Dell'Anna, L.; Mamcini, L. (1998): *Somatochlora meridionalis* Nielsen, 1935 nel Lazio (Italia centrale), con note di autecologia e comportamento (Odonata: Corduliidae). *Opusc. zool. flumin.* 163: 1-16. (in Italian, with English summary). ["The 12 hitherto known *Lalium* localities of the species are mapped. At 5 sites, in 2 streams, the temperature, pH, dissolved oxygen, oxygen saturation, conductivity and salinity were recorded, and the concentration of sulfite-reducing clostridia was evidenced in water and in sediments by means of anaerobic culture on SPS-agar. In winter, during the larval stage, water was cool and oversaturated by oxygen, pH was over 8. Since water bodies with such pH values are uncommon in central Italy, the high alkalinity might present a restricting factor for larval growth, hence it could be responsible for the localised distribution of the species. Mature individuals were recorded on the wing between early July and the second half of August, but the entire flight period, incl. the maturation time, probably extends from mid June to the end of August at least. Throughout this period, 13 odonate species were associated with *S. meridionalis* at 3 of its habitats. There is no evidence on territorial behaviour. Males search for females in the shadedmost parts of the river banks. However, the copulation takes place either at the watersite or, in 1 case, it occurred 2 km off the water. This may suggest an unusual mating system in this species. Intra-male sperm translocation behaviour was observed once, after tandem formation. The oviposition takes place at very sheltered and shaded sites, either in the water, or in the mud at the water edge. At times, females can also repeatedly alternate several oviposition movements onto the ground (at a short distance from water) with a single one onto the water. Eggs, deposited on 22 August 1997, and reared first under natural conditions, and subsequently in the laboratory (15 h light period), hatched after 29 days. The female preference for very shaded oviposition sites might explain the literature reports on larvae, recovered from flooded caves and Etruscan tombs, although these can be carried into the caves by the surface streams as well." (in Hungarian with English summary). [The paper documents the odonate fauna of the Varbó reservoir in the Tardonai Hills, Hungaria. 29 species, most of them collected in 1995 and 1996, are listed. Special emphasize is given by the authors to *Pyrrhosoma nymphula interposita*, *Aeshna mixta*, *Anax imperator*, *Libellula fulva*, and *Sympetrum pedemontanum*.] Address: Vizslán, V., Kitaibel Pál út 32/C Fsz: 2, HU-9400 Sopron, Hungaria

1999

2700. Angelibert, S.; Cayrou, J.; Cereghino, R.; Giani, N. (1999): Biodiversity of three rocky ponds of the "Causses du Quercy" Regional Natural Park. *Bulletin de la Societe D'Histoire Naturelle de Toulouse* 135: 37-45. (in French with English summary). ["In the arid Causse region (South-western France), aquatic ecosystems are scarce, and essential to the maintain of both wildlife and human activities. Since the 12th century, several ponds were bored into the calcareous rock of this region. These man-made ecosystems belong now to the patrimony of the "Causses du Qercy" Regional Natural Park. The aim of this work was to evaluate the biodiversity of the aquatic flora and fauna of these ponds. Because of the rocky nature of the substrate, the specific richness of the flora was low (only 13 plant species were recorded). The invertebrate and vertebrate fauna was sampled from March to July 1999 :155 taxa (i.e. 145 invertebrates and 10 vertebrates) from 61 families were recorded. These taxa were characteristic of plains and mountains from occidental Europe. However, this species list is certainly not extensive. Most of the winged adults could be considered as migrating species (i.e. from pond to pond), with reproduction occurring in a certain number of ponds only. Diptera Chironomidae were the most diversified group, with 33 identified taxa. The absence of expected taxa (i.e. usually found in such ecosystems: Odonata Gomphidae, Mollusca Sphaeriidae) was probably due to the absence of mud accumulation on the rocky substrate. Our study showed that these ponds require particular attention and should be preserved, as : i) they could be considered as isolated biodiversity reservoirs within this wide arid area, and ii) they are the only of water for the terrestrial fauna, including insects which have a major role in plant pollinisation." (Authors)] Address: Angelibert, S., Centre d'Ecologie des Systemes Aquatiques Continentaux, UMRC 5576, 118 route de Narbonne, F-31062, Toulouse Cedex, 4 France

2703. Inoue, K.; Kano, K.; Kuwahara, H.; Sano, O.; Yahiro, I. (1999): Records of Odonata from Guam Island, Mariana Islands, USA. *Sympetrum Hyogo* 6: 14-22. (in Japanese with English summary). ["Many Japanese travelers have visited this island mainly for sight-seeing, but no faunal records have ever been published after Lieftinck's publication on Odonata of Micronesia in 1962. This report compiles specimens collected by Kano, Kuwahara, Sano and Yahiro, who have visited this island during 1983 to 1997 independently. The twelve species listed by Lieftinck for Guam, could be confirmed. *Orthetrum s. sabina*, *Zyxomma petiolatum*, and *Macrodiplax cora* are new additions to this island (cf. Kano, 1990 and 1991), and *Anax guttatus* was proved to occur in good numbers in contrast to Lieftinck's single female. The status of *Anax piraticus* is discussed in comparison with *A. guttatus* and *A. panybeus* in great detail and the taxa are figured. Figures of *Agrionoptera insignis guamensis* and the Japanese *A. i. insignis* are welcome for studying the status of the taxa. Some of the species are pictured with colour photos, and a picture shows a couple of *O. sabina* and *Z. petiolatum*. In addition body length of *Hemicordulia mindana mindana* and *H. m. nipponica* are compiled in a table." (Authors)] Address: Inoue, K., 5-9 Fuminosato 4-chome, Abeno-ku, Osaka 545, Japan

2718. Boonthai, C.; Scott, R.R. Chapman, R.B. (2000): Acetylcholinesterase as a biomarker to assess the effect of chlorpyrifos and atrazine on some New Zealand aquatic invertebrates. *Australasian Journal of Ecotoxicology* 6(1): 59-64. (in English). ["Acetylcholinesterase (AChE) activity was investigated in selected species of New Zealand aquatic invertebrates using a modified microplate assay based on the Ellman technique as a biomarker of chlorpyrifos and atrazine exposure. After two days exposure to different concentrations of chlorpyrifos and atrazine, mayfly nymphs, *Deleatidium* sp., common water boatman, *Sigara arguta*, and common red damselfly nymphs, *Xanthocnemis zealandica*, showed a general trend of depression in AChE level but there were differences between the species. The results indicate that acetylcholinesterase may be useful as a biomarker but the choice of species is critical. The results also showed that atrazine may inhibit the activity of AChE. These results suggest that the restriction of AChE as a biomarker for organophosphorus and carbamate pesticides may not be valid and the use of this enzyme as a biomarker may be able to extended." (Authors)] Address: Boonthai, C.; Ecology and Entomology Group, Soil, Plant, and Ecological Sciences Division, Lincoln University, Canterbury New Zealand.

2719. Brown, J.M.; McPeck, M.A.; May, M.L. (2000): A phylogenetic perspective on habitat shifts and diversity in the North American *Enallagma* damselflies. *Systematic Biology* 49(4): 697-712. (in English). ["Community ecologists are increasingly aware that the regional history of taxon diversification can have an impor-

tant influence on community structure. Likewise, systematists recognize that ecological context can have an important influence on the processes of speciation and extinction that create patterns of descent. We present a phylogenetic analysis of 33 species of a North American radiation of damselflies (Zygoptera: Coenagrionidae: *Enallagma* Selys), which have been well studied ecologically, to elucidate the evolutionary mechanisms that have contributed to differences in diversity between larval habitats (lakes with and without fish predators). Analysis of molecular variation in 842 bp of the mitochondrial cytochrome oxidase I and II subunit and of the intervening Leu-tRNA and 37 morphological characters resulted in three well-defined clades that are only partially congruent with previous phylogenetic hypotheses. Molecular and morphological data partitions were significantly incongruent ($p < .01$). Lack of haplotype monophyly within species and small amounts of sequence divergence (<1%) between related species in three of the four clades suggest that recent, and parallel, speciation has been an important of community diversity. Reconstruction of habitat preference over the phylogeny suggests that the greater species diversity in fish-containing lake habitats reflects the recency of shifts into the fishless lake habit, although a difference in speciation or extinction rates between the two habitats is difficult to exclude as an additional mechanism." (Authors)] Address: May, M.L., Dept Entom., New Jersey Agricultural Experiment Station, Cook College, Rutgers Univ., New Brunswick, NJ 08901-8524, USA. E-mail: may@aesop.rutgers.edu

2720. Chae, J.-S.; Pusterla, N.; Johnson, E.; Derock, E.; Lawler, S.P.; Madigan, J.E. (2000): Infection of aquatic insects with trematode metacercariae carrying *Ehrlichia risticii*, the cause of Potomac horse fever. *Journal of Medical Entomology* 37(4): 619-625. (in English). ["We provide evidence of *Ehrlichia risticii* Holland, the agent of Potomac horse fever, in trematode stages found in aquatic insects collected from a pasture stream in northern California, using nested polymerase chain reaction (PCR) amplification and sequence analyses of the 16S rRNA, 51 kDa major antigen and groEL heat shock protein genes. *E. risticii* was detected in metacercariae found in the immatures and adults of the following insects: caddisflies (Trichoptera), mayflies (Ephemeroptera), damselflies (Odonata, Zygoptera), dragonflies (Odonata, Anisoptera), and stoneflies (Plecoptera). The prevalence of *E. risticii* was 31.9% ($n = 454$ individuals) in aquatic insects (13 of 17 species were positive). Prevalence within orders was as follows: 43.5% ($n = 207$) in caddisflies, 15.2% ($n = 92$) in mayflies, 13.9% ($n = 115$) in damselflies, 10.0% ($n = 10$) in dragonflies, and 80.0% ($n = 30$) in stoneflies. This study demonstrates a broad intermediate host range for trematodes that act as vector for *E. risticii*. Insects are likely to play an important role in the epidemiology of this disease." 2721. Combes, S.A.; Trimble, A.C.; Daniel, T.L. (2000): Spatial profiles of wing stiffness in hawk-moths and dragonflies. *American Zoologist* 40(6): 978. (in English). ["Insect flight performance depends strongly on the dynamic geometry of wings. The curvature of the trailing edge, in particular, is a crucial determinant of aerodynamic force generation. In insects, wing curvature results from the instantaneous interaction between

aerodynamic forces and bending stiffness. If bending stiffness varies spatially, then regional flow control is possible, suggesting a passive mechanism of stability. To examine this structural heterogeneity and its consequences for flight aerodynamics, we characterize spatial variation of wing flexural stiffness in both the spanwise and chordwise direction of insect wings. We measure the surface shape of wings by multiple laser ranging techniques, and then calculate flexural stiffness along the wing by comparing the surface shape of wings before and after loading the tip with a known force. We compare the spatial distribution of wing stiffness in the hawkmoth, *Manduca sexta*, and an aeshnid dragonfly, *Aeshna multicolor*. These insects, both excellent fliers, differ greatly in wing shape and venation pattern. Despite such morphological differences, we find that the profile of flexural stiffness in the spanwise direction is remarkably similar in both species, with a peak in stiffness located between 1/3 and 1/2 of wing span, and a sharp drop in stiffness (apprx2 fold) past this point. In contrast, chordwise stiffness differs in the two species; in *Manduca*, stiffness falls sharply towards the trailing edge, while the dragonfly does not display this abrupt drop. Thus, trailing edge curvature and chordwise flow may differ significantly in these species." (Authors)] Address: Combes, S.A. ; Trimble, A. C. ; Daniel, T. L., University of Washington, Seattle, WA USA

2722. Fischer, S.; Marinone, M.C.; Fontanarrosa, M.S.; Nieves, M.; Schweigmann, N. (2000): Urban rain pools: Seasonal dynamics and entomofauna in a park of Buenos Aires.. *Hydrobiologia* 441: 45-53. (in English). ["We describe the seasonal variations of the insect community of the rain pools in a park of Buenos Aires during a 1-year period, based on a weekly sampling programme. We also analyse the relationships between the observed biotic patterns and some physical and meteorological variables. Four periods, fairly coincident with the seasons of the year, were graphically identified as functions of temperature, rainfall, flooded area, number of rain pools, depth and taxonomic richness. A total of 45 insect taxa was identified: 18 Coleoptera, 15 Diptera, 9 Heteroptera, 1 Ephemeroptera and 2 Odonata. [...]."] (Authors). [Between 1996 and 1998, 46 odonate species were recorded from 93 water bodies within open-cast lignite post-mining landscapes of Sachsen-Anhalt, Germany. From the nature conservation point of view, the most important habitats are those with good water quality and a high diversity of vegetation. Each species is discussed in some detail. Succession of water body (early phase, transition phase, established phase [>35 years old]) and the specific odonate species are outlined. This paper provides significant information on the characteristic coenosis and key species of different water bodies.] Address: Huth, J., OEKOKART GmbH, Georg-Cantor-Str. 31, D-06108 Halle/Saale, Germany

2729. Iannacone, J.A.; Alvarino, L.; Moreno, R.; Reyes, M.; Chauca, J. (2000): Culicidos (Diptera) del rio Chillón y sectores adyacentes de la provincia constitucional del Callao, Peru, durante El Niño 1997-1998. *Acta Entomologica Chilena* 24: 51-60. (in Spanish with English summary). [The study evaluated some areas of natural breeding places of mosquitoes - in most cases near underdeveloped town - near human populations in Callao-Peru during December 97 to August 98. Larvae of culicids of medical importance as *Anopheles pseudopunctipennis* (Theobald), *Culex quinquefasciatus* (Say), and *Aedes taeniorhynchus* (Wiedemann) were assessed. Habitat conditions resp. requirements of the species as salinity, temperature, and pH (7,8) were analyzed. "Moreover, spatial and temporal variation of population and the larvae index were observed in nine

survey points of Chillan River. High larvae indexes of *A. pseudopunctipennis* were associated with presence of the algae *Cladophora glomerata* (L.) Kuetzing and with the macrophyte *Lemna minor* (L.). The larvivorous fish *Poecilia reticulata* Peters, nymphs of Libellulidae and Coenagrionidae (Odonata) and adults of Dytiscidae (Coleoptera) were recorded as potential predators. The results were compared with those of the 1995-96 Pre-ENSO event, concluding that one of the consequences of Southern Oscillation ENSO "El Niño" 1997-98 event in the Peruvian coast was an increase of the population of these culicids of medical importance." (Authors)] Address: Iannaccone, J.A., Laboratorio de Ecofisiología, Área de Biodiversidad Animal, Facultad de Ciencias Naturales y Matemáticas, Universidad Nacional Federico Villarreal, Calle San Marcos 383, Pueblo Libre, Lima 21, Peru. 2731. Jonsen, I.; Taylor, P.D. (2000): Calopteryx damselfly dispersions arising from multiscale responses to landscape structure. *Conservation Ecology*. [online] 4(2). [cited September 14, 2001] Dec, 2000. 1-29. <http://www.consecol.org/Journal/vol4/iss2/art4/index.html>: (in English). ["Using spatially explicit simulation models, we explored the extent to which fine-scale (i.e., meters to tens of meters) movement behaviors could be used to predict broader scale patterns of distribution on heterogeneous landscapes. Our models were tailored by empirical data on Calopterygid damselfly movements on three types of landscapes that differed in amount of forest habitat. Surveys of the two congeneric damselflies, *C. aequabilis* and *C. maculata*, demonstrated that both species occupied stream and forest habitats on forested and partially forested landscapes, but were found primarily along streams on nonforested landscapes. Simulation models whose parameters were derived using empirical movement data for both species showed that fine-scale movement behaviors could be used to predict, on average, broader scale dispersion across a range of landscape structures, but that it was necessary to include information about broader scale landscape features in those models. In particular, the probability of crossing a patch boundary (patch boundary permeability) and the rate of movement in a given habitat patch (patch viscosity) were important determinants of damselfly dispersion on heterogeneous landscapes. In other words, our results suggest that damselfly dispersions may arise as a function of behavioral responses to spatial patterns at multiple scales." (Authors)] Address: Jonsen, D.I., Lethbridge Research Centre, Agriculture & Agri-Food Canada, P.O. Box 3000, Lethbridge, AB, Canada T1J 4B1. E-mail: jonse- ni@em.agr.ca

2734. Kúdela, M. (2000): On the occurrence of some dragonflies (Odonata) in Podunajská rovina Plain. *Entomofauna carpathica* 12: 32-33. (in Slovakian, with English summary). [Trpis (1957) published odonate records from the Podunajská rovina Plain. The red listed *Stylurus flavipes* and *Sympetrum depressiusculum* have been rediscovered in this region; *Aeshna cyanea* has been recorded for the first time. *Gomphus pulchellus*, listed for the Podunajská rovina Plain, turns out to have been misrecorded, "as the place of record does not belong to this area." Annotation of ms: *G. pulchellus* was published for the Slovakian Republic from Dudich, E. (1958): Die Grundlagen der Fauna eines Karpaten-Flusses. *Acta zool. Acad. sci. hung.* 3(3-4): 179-200; the correct identification of the specimen is questionable.] Address: Kúdela, M., Katedra zoológie Prírodovedeckej fakulty UK, Mlynská dolina B-1, 842 15 Bratislava, Slovakia

2735. Mostert, K. (2000): Fauna in de stad: Mogelikheden en beperkingen. *Levende Natuur* 101(6): 209-212. (in Dutch with English summary). ["Fauna in urban areas: Chances and limitations: In general urban areas host a large number of fauna species. Many of these species roam a lot. Far less species manage to maintain vital populations in urban areas. In larger cities most species are found in the sub-urban areas. Specific management offers especially in these areas attractive ecological possibilities. Apart from some building dwelling species the urban bird fauna consists mainly of forestborn species. Settlement of colonies causes often conflicts with 'human' fauna. Water birds and birds nesting on the ground are rare, because of predating pets. For example White wagtail, Swallow and Tree sparrow breed in rural areas in or around human buildings, but are largely absent in urban areas. Bats indicate ecological infrastructure in urban areas. The ecological quality of lawns in recreational areas and roadsides is well indicated by abundance and diversity of butterflies and grasshoppers. Dragonflies and in a lesser extent amphibians are suitable for judging the suc-

cess of riparian ecological management. Opportunities for ecological successes are linked to ecological corridors, extensive grassland management and in riparian management. Vegetations consisting of ruderal plant species are important in suburban areas, whereas these can accommodate many species, which lack in urban areas. Exotic species like Ring-necked parakeet, Siberian chipmunk and Midwife toad increase as a part of the urban fauna. Contrary to the flora the urban fauna hardly contains rare (Red List) species." (Author)] Address: Mostert, K., Palamedesstraat 74, NL-2612 XS Delft, The Netherlands

2736. NABU (2000): Das NABU-Naturschutzprojekt "Vogelsbergteiche" - ein einmaliges Naturidyll in Deutschland wird vorgestellt. Jahrbuch Naturschutz in Hessen 5: 7-9. (in German). [These water bodies are situated in the high middle range mountains in Hessen, Germany and of special ornithological importance. A passing reference on Odonata states that the population density of *Enallagma cyathigerum* was projected to 300000 individuals. So far 16 species are known from the region, but only *Aeshna mixta* is specified.] Address: NABU, Landesverband Hessen, Garbenheimer Str. 32, D-35578 Wetzlar, Germany. www.NABU-Hessen.de

2737. Niesler, A. (2000): Ocena jakosci wody potoku Slepjotka na podstawie badan sestonu oraz bentosu. *Acta Biologica Silesiana* 34(51): 97-118. (in Polish with English and Russian summaries). ["Estimation of the water quality in Slepjotka stream on the ground of seston and bentos investigations: Studies concerned qualitative and quantitative analysis of seston and bentos fauna communities of the stream Slepjotka (Upper Silesia). Samples were taken from March to November 1996, once a month. Ciliata were the group which dominated in number and variety in species. Qualitative and quantitative analysis were helpful in distinguishing three different zones: the clean water zone (corresponded with oligosaprobic zone - next to the spring), the strong polluted zone (corresponded with alpha-mesosaprobic zone with some polisaprobionts - in the middle site) and the self-clarificated one (corresponded with alpha-mesosaprobic zone with some oligo- and beta-mesosaprobionts - near the fall of Slepjotka into Klodnica River). The communal sewage which flew down into the stream had a double influence over organisms living there. On the one hand it was connected with degradation of Ostracoda, Coleoptera, Dixidae, Heleidae, Ephemeroptera, Heteroptera, Odonata, Plecoptera (in bentos) and Cladocera (in seston). On the other hand it caused the massive occurrence of Ciliata, Nematoda and Diptera. Taking into account variety of trophic types, the lowest number of bacteria-feeders at the clean zone and their higher amount in the remaining sites were recorded. In spite of fact that the qualitative composition of bentos was indicative of greater pollution than in seston, the bentos communities as well as the seston one were helpful in estimating of the water quality." (2000): Effects of ditch management on caddisfly, dragonfly and amphibian larvae in intensively farmed peat areas. *Aquatic Ecology* 34(4): 397-411. (in English). ["Conservation of natural values within farming practice is growing rapidly within the Netherlands. The focus is primarily on terrestrial flora and fauna such as the vegetation in ditch banks and meadow birds. Knowledge needed to enhance biodiversity in ditches is limited. Therefore, a field study was set up to determine the effects of dredging, ditch cleaning and nutrient supply in the adjacent fields on caddisfly, dragonfly and amphibian larvae in the ditches in a peat area. Two-hundred forty ditches spread over 84 dairy farms were selected to determine the individual effect of several management aspects. Generalised linear modelling was used as a tool to detect the most relevant aspects and to obtain quantitative relations with the chance of the larvae being present. Dredging had an impact on the presence of all larvae types. The type of dredging machine, the dredging period, the water depth and the frequency of dredging can influence the presence of the larvae. The presence of caddisfly larvae was also affected by the cleaning machine and period and by the P supply in the adjacent field. The presence of amphibian larvae was also affected by the cleaning period. Measures that will enhance the presence of the larvae are formulated. Options for water boards and other government authorities to stimulate farmers to take these measures are given." (Authors) *Coenagrion pulchellum*, *Erythromma najas*, *Ischnura elegans*, and *Chalcolestes viridis* are listed in tab. 2.] Address: Twisk, W., Section Environmental Biology, Institute of Evolutionary and Ecological Sciences, Leiden University, 2300 RA, Leiden, The Netherlands. 2758. Arnold, A. (2001): Neue Nachweise von Gomphiden (Odonata) im Regierungsbezirk Leipzig (Sachsen) und am Bitterfelder Muldestausee (Sachsen-Anhalt). Veröff. Naturkundemuseum Leipzig 20: 62-65. (in German). [Emerging Gomphus vulgatissimus were found on 15 May 2001 along the shore of the Muldestausee near Bitterfeld, Sachsen-Anhalt, Germany; the emerging habitats are characterised. In addition, the species occurs in the river Mulde (Sachsen). Comparable to *Calopteryx splendens*, *G. vulgatissimus* seems to recolonise some of the formerly heavily impacted rivers in the eastern parts of Germany. 11 and 14 July 2001 (a freshly emerged) *Ophiogomphus cecilia* was recorded near Scholtitz, Sachsen. This is one of the rare Saxonian records of the species which are also documented.] Address: Arnold, A., Zur schönen Aussicht 25, D-04435 Schkeuditz, Germany

2759. Baptista, D.F.; Buss, D.F.; Dorville, L.F.M.; Nessimian, J. L. (2001): Diversity and habitat preference of aquatic insects along the longitudinal gradient of the Macae River basin, Rio de Janeiro, Brazil. Brazilian Journal of Biology 61(2): 249-258. (in English with Portuguese summary). ["Diversity and habitat preference of macroinvertebrates were studied in Macae River basin, Rio de Janeiro State, Brazil, along its longitudinal gradient. We selected stream reaches corresponding to

1st, 2nd, 4th, 5th and 6th orders. A Surber sampler was used to collect four macroinvertebrates samples of each substrate (sand, litter in pool areas, stones, and litter in riffle areas) during the three sampling periods, defined based on the rain regime: April (end of the rainy season), July (dry season), and October (beginning of the rainy season). We identified 46,431 specimens corresponding to 117 taxa. Analysis of diversity numbers (both for family or genus level) indicated that all insect taxonomic orders had higher numbers on 2nd order stream reach, except for Ephemeroptera, on 4th order. However when considering morph-species taxonomic level, the higher diversity number occurred on 4th order stream. The highest richness and diversity numbers were found at the dry season. Considering habitat preference, both litter in pool areas and litter in riffle areas had the highest faunal richness." (Authors)] Address: Baptista, D.F., Laboratorio de Avaliacao e Promocao da Saude Ambiental, Departamento de Biologia, IOC, Fiocruz, Av. Brasil, 4.365, CEP 21045-900, Manguinhos, Rio de Janeiro, Brazil. E-mail: darcilio@gene.dbbm.fiocruz.br

2760. Bechly, G. (2001): A new species of *Cymatophlebia* (Insecta: Odonata: Anisoptera: Cymatophlebiidae) from the Solnhofen lithographic limestone (Upper Jurassic, Germany). Stuttgarter Beiträge zur Naturkunde Serie B (Geologie und Palaeontologie) 301: 1-5. (in English). ["A new dragonfly species, *Cymatophlebia densa* n. sp. (Anisoptera: Aeshnoptera: Cymatophlebiidae), is described from the Upper Jurassic Solnhofen Limestone of Germany. It is the fourth species of this Mesozoic genus known from this famous fossil locality." (Author)] Address: Bechly, G., Staatliches Museum für Naturkunde, Abt. Paläontologie, Rosenstein 1, D-70191 Stuttgart, Germany. E-mail bechly@gmx.de

2761. Bechly, G.; et al. (2001): A revision and phylogenetic study of Mesozoic Aeshnoptera, with description of numerous new taxa (Insecta: Odonata: Anisoptera). Neue Paläontologische Abhandlungen 4. ISBN 3-931689-07-7: 230 pp., 137 textfig., 48 pls. (in English with German summary). ["All Mesozoic Aeshnoptera are revised and their phylogenetic relationships are reconstructed. The type species of the genus *Mesuropetala* is redescribed, and *Mesuropetala muensteri* (GERMAR, 1839) comb. nov. is considered as its valid name instead of *Mesuropetala koehleri* (HAGEN, 1848). *Mesuropetala magna* sp. nov. is described from the Lower Cretaceous of Russia. "*Aeschna*" *antiqua* VANDER LINDEN, 1827 and "*Aeschna*" *schmiedeli* GIEBEL, 1856 could be synonyms of *Mesuropetala muensteri* or *Protolindenia wittei*, and thus are here considered as nomina dubia in Anisoptera incertae sedis. *Cymatophlebiopsis pseudobubas* HANDLIRSCH, 1939 is regarded as junior subjective synonym of *Aeschnopsis perampla* (BRODIE, 1945), and the genus *Aeschnopsis* HANDLIRSCH, 1939 stat. restor. is transferred to *Mesuropetalidae*. *Necrogomphus jurassicus* (GIEBEL, 1856) from the Lower Cretaceous of England is attributed to the genus *Aeschnopsis*. Furthermore, two new species, *Aeschnopsis perkinsi* sp. nov. and *A. tischlingeri* sp. nov. are described from the Upper Jurassic of Germany. *Liupanshanina* HONG, 1982 (*L. sijiensis* HONG, 1982) is transferred from Aeshnidae to a new family *Liupanshaniidae* fam. nov. that is regarded as sistergroup of *Mesuropetalidae*, and also includes the new taxa *Paramesuropetala gigantea* gen. et sp. nov. and *Araripeliupanshanina annesusae* gen. et sp. nov.

from the Lower Cretaceous of Brazil, *Paraliupanshania torvaldsi* gen. et sp. nov. and *P. rohdendorfi* sp. nov. from the lower Upper Cretaceous of Russia, and *Paraliupanshania britannica* sp. nov. from the Lower Cretaceous of England. *Progobiaeshna liaoningensis* gen. et sp. nov. is described from the Lower Cretaceous of China in a new family *Progobiaeshnidae* fam. nov. which is regarded as sistergroup of *Aeshnida* within *Aeshnomorpha* taxon nov. - *Panaeshnida* taxon nov. *Gobiaeshna PRITYKINA, 1977* (*G. occulta PRITYKINA, 1977*) is preliminarily attributed to *Progobiaeshnidae* fam. nov. as well. *Cymatophlebia longialata* (MÜNSTER in GERMAR, 1839) from the Upper Jurassic of Germany is redescribed and all *Cymatophlebiidae* are revised. Curious (autapomorphic) structures on the male abdomen of *Cymatophlebia* and *Rudiaeshna* are described in detail and their function is discussed. The phylogenetic position of *Cymatophlebiidae* within *Anisoptera* is discussed and seven new species are described: *Cymatophlebia kuempeli* sp. nov., *Cymatophlebia pumilio* sp. nov., *Cymatophlebia suevica* sp. nov., and *Cymatophlebia herrlenae* sp. nov. from the Upper Jurassic of Germany, as well as *Cymatophlebia purbeckensis* sp. nov., *?Valdaeshna andressi* sp. nov., and *Prohoyaeshna milleri* gen. et sp. nov. from the Lower Cretaceous of England. "*Cymatophlebia*" *mongolica* COCKERELL, 1924 is transferred as nomen dubium to *Anisoptera incertae sedis*. *Libellulum* WESTWOOD, 1854 is rejected as synonym of *Cymatophlebia*, and its type species *L. agrias* WESTWOOD, 1854 is regarded as nomen dubium, probably belonging to *Valdaeshninae* subfam. nov. within *Cymatophlebiidae*. The two holotype specimens of *Cymatophlebia suevica* sp. nov., and *Cymatophlebia herrlenae* sp. nov. represent the first and currently sole fossil insect remains known from the Malm beta of the Swabian Alb in Southern Germany. These two new species furthermore have to be regarded as the oldest known crown-group representatives of *Anisoptera*. With an estimated wing span of more than 220 mm, *Cymatophlebia suevica* sp. nov. and *Prohoyaeshna milleri* gen. et sp. nov. seem to represent the biggest *Anisoptera* and even the biggest crown-group *Odonata* known at all. *Rudiaeshnidae* fam. nov. is proposed as new family for *Rudiaeshna limnobia* DONG & ZI-GUANG, 1996 (Lower Cretaceous, China). This new family is regarded as sistergroup of *Cymatophlebiidae* and classified with the latter in a new superfamily *Cymatophlebioidea* stat. nov. *Paracymatophlebia splendida* gen. et sp. nov. from the Upper Jurassic of Kazakhstan is described in a new family *Paracymatophlebiidae* fam. nov. which is regarded as sistergroup of *Euaeshnida* (together: *Panaeshnida* taxon nov.). *Eumorbaeshnidae* fam. nov. from the Upper Jurassic of Germany is proposed as most basal family of *Euaeshnida*, based on *Eumorbaeshna jurassica* (CARPENTER, 1932) gen. et comb. nov. as "replacement" name for the aeshnid described by NEEDHAM (1907) under the incorrect name "*Morbaeshna muensteri*" because of a misidentified type species. The genus *Morbaeshna* NEEDHAM (1907) is synonymized with the genus *Mesuropetala*. *Anomalaeshna berndschusteri* gen. et sp. nov. (Lower Cretaceous, Brazil), *Paramorbaeshna araripensis* gen. et sp. nov. (Lower Cretaceous, Brazil), *Progomphaeshnaoides ursulae* gen. et sp. nov. and *Progomphaeshnaoides staniczeki* sp. nov. (Lower Cretaceous, Brazil), *Plesigomphaeshnaoides mongolensis* gen. et sp. nov. (Lower Cretaceous, Mongolia) and *Plesigomphaeshnaoides pindelskii* sp. nov. (Lower Cretaceous, England) are described

within *Neoaeshnida* - *Gomphaeshnidae* in a new subfamily *Gomphaeshnaoidinae* subfam. nov. In the same group three new species, *Gomphaeshnaoides magnus* sp. nov., *Gomphaeshnaoides petersi* sp. nov., and *Gomphaeshnaoides betoreti* sp. nov. are described from the Lower Cretaceous of Brazil, together with a redescription of the type species *Gomphaeshnaoides obliquus*, including its previously unknown forewings and body. "*Gomphaeshna*" *paleocenica* and "*Gomphaeshna*" *danica* from the Palaeocene of Denmark are preliminarily transferred to the new genus *Plesigomphaeshnaoides* gen. nov. as well. *Sinojagoria imperfecta* gen. et sp. nov. is described from the Lower Cretaceous of China and regarded as most basal representative of *Gomphaeshnaoidinae* subfam. nov. *?Gomphaeshna sibirica* sp. nov. and *Baissaeshna zherikhini* sp. nov. are described from the Lower Cretaceous of Russia. The genus *Cymatophlebiella* PRITYKINA, 1968 is excluded from *Cymatophlebiidae* and regarded as a basal *Aeshnoptera incertae sedis*; its type species *C. euryptera* PRITYKINA, 1968 is redescribed. Several taxonomic errors in LOHMANN (1996a-c) are corrected. Some general conclusions concerning the evolution and historic biogeography of *Aeshnoptera* are suggested, including an Mid-Jurassic Palaeartic origin and radiation of this monophylum. Totally 26 genera and 52 species of fossil dragonflies are revised. The following new taxonomic decisions are found in this publication: 5 taxa nov., 5 fam. nov., 2 subfam. nov., 2 trib. nov., 12 gen. nov., 29 sp. nov., 8 syn. nov., 5 stat. nov., 6 comb. nov., 2 nom. correct., 3 stat. restor., 3 sensu nov., 5 pos. nov." (Authors)] Address: Bechly, G., Staatliches Museum für Naturkunde, Abt. Paläontologie, Rosenstein 1, D-70191 Stuttgart, Germany. E-mail bechly@gmx.de

2762. Bezdecka, P. (2001): A contribution to the knowledge about Dragonflies (*Odonata*) of the Vizovické vrchy Highlands and Hlucka pahorkatina Highlands (Moravia, Czech Republic). *Vázky* 2001. Sborník referátu IV. celostátního semináře odonatologu, který se konal v Národním parku Sumava 2. - 5. 8. 2001. Seminár usporádali: ZO CSOP Vlasim, Správa NP Sumava, Správa. CHKO Blaník: 50-61. (in Czech with English summary). [In 2000, 25 localities were sampled for *odonata*. A total of 40 species including *Coenagrion pulchellum*, *Erythromma viridulum*, *Brachytron pratense*, *Aeshna affinis*, *Gomphus vulgatissimus*, *Ophiogomphus cecilia*, and *Thecagaster bidentata* are compiled, arranged according their locality frequency, and briefly commented.] Address: Bezdecka, P., V. 2763. Bryer, P.J.; Glanz, W.E. (2001): Oviposition site selection by a tropical treefrog in a temporary pool environment. *American Zoologist* 41(6): 1639. (in English). ["Frogs that oviposit unguarded aquatic eggs display various strategies to help ensure their offspring's survival. At one extreme, frogs can rely on camouflage or aversive taste to protect their eggs from predators, particularly fish. Alternatively, frogs can lay eggs in places where predators cannot survive, such as in temporary pools. These ephemeral environments, although typically fishless, still possess risks from the presence of predatory invertebrates and possibility of the pool drying up before the young metamorphose. To compound the difficulty faced by ovipositing pairs, pools that are free of predators may be very small and ephemeral,

while other pools that are more likely to persist for the entire period of development usually contain predatory invertebrates. We tested whether a temporary-pool breeding frog (*Hyla parviceps*) would discriminate between these pools. Thirty-five temporary pools near Posadas Amazonas, Madre de Dios province, Peru were censused daily for egg deposition. The pools were monitored weekly for invertebrate predators (primarily odonates), tadpole competitors of the families Hylidae and Leptodactylidae, and abiotic measurements (DO, pH, temperature, surface area, and depth). When the numbers of eggs laid in predator-free pools were compared with those pools containing predators a significant positive correlation between predator abundance and number of eggs laid was found. However, the main predictor of both predator abundance and the number of eggs laid was pool permanency, as estimated from pool volume. We feel that the frogs are choosing to ignore the risk posed by aquatic invertebrate predators because the alternative, drying risk, is greater in the smaller temporary pools." (Authors)] Address: Bryer, P.J.; Glanz, W.E., University of Maine, Orono, ME USA

2764. Catling, P.M.; Brownell, V.R. (2001): Biodiversity of adult damselflies (Zygoptera) at eastern Ontario gravel pit ponds. *Canadian Field-Naturalist* 115(3): 402-405. (in English). ["Adults of twenty-five species of damselflies were recorded at 41 gravel pit ponds in eastern Ontario. Twenty-four of the species recorded are believed to breed in the ponds where they were captured. Species present at 16 or more of the sites included *Enallagma boreale*, *E. civile*, *E. cyathigerum*, *E. ebrium*, *E. hageni*, *Ischnura verticalis*, *Lestes forcipatus*, *L. unguiculatus*, and *Nehalennia irene*. Two provincially and regionally rare species, *Lestes eurinus* and *Enallagma aspersum*, were abundant in some of the pit ponds. With 70% of the eastern Ontario zygopteran fauna, these naturally colonized sites may serve as important habitats for the conservation of biodiversity. The relatively high overall diversity compared to the much lower within-pond diversity is probably related to variation between ponds in flora, fauna, depth and other characteristics. Species specific associations with characteristics of the water body other than chemistry, may make damselflies a valuable group of bioindicators." (Authors)] Address: Catling, P.M., 2326 Scrivens Drive, R.R. 3, Metcalfe, Ontario K0A 2P0, Kanada. E-mail: brownell@achilles.net

2765. Cempírek, J. (2001): Dragonflies (Odonata) of the town Ceske Budejovice (Southern Bohemia). Part II, the pond Bagr in Stromovka (1985-86, 2001). *Vázky* 2001. Sborník referátu IV. celostátního seminare odonatologu, který se konal v Národním parku Sumava 2. - 5. 8. 2001. Seminár usporádali: ZO CSOP Vlasim, Správa NP Sumava, Správa. CHKO Blaník: 109-123. (in Czech with English summary). [Faunistical data from this Czech locality, resulting from 1985 and 1986 (26 species) are compared with data from 2001 (12 species). In the 1980ies the pond was in nearly natural condition including species as *Leucorrhinia dubia* and *L. pectoralis*. Later, the pond was amended to a concrete recreational reservoir. Most of the species were lost, but *Erythromma viridulum* and *Anax parthenope* are new immigrants to the locality.] Address: Cempírek, J., Vidov 37, 370 07 České Budejovice, Czech Republic

2771. De Marmels, J. (2001): Revision of Megapodagrion Selys, 1886 (Insecta, Odonata: Megapodagrionidae). Dissertation, Mathematisch-naturwissenschaftlichen Fakultät, Universität Zürich: 220 pp. (in English with German summary). ["The South American genus Megapodagrion Selys is split into Megapodagrion s. str. [monotypic: megalopus (Selys)], Allopodagrion Förster rev. status, [three species, viz., brachyurum sp. n., conortum (Hagen) (type species), erinys (Ris) comb. n., and Teinopodagrion gen. n. [24 species, viz., angulatum sp. n., caquetanum sp. n., chinchaysuyum sp. n., curtum (Selys) comb. n., decipiens sp. n., depressum sp. n., epidrium sp. n., eretes sp. n., lepidum (Racenis) comb. n., macropus (Selys) comb. n. (type species), mercenarium (Hagen) comb. n., meridionale sp. n., muzanum (Navas) comb. n., nebulosum (Selys) comb. n., oscillans (Selys) comb. n., schiessi sp. n., setigerum (Selys) comb. n., temporale (Selys) comb. n., turikum sp. n., vallenatum sp. n., venale (Selys) comb. n., vilorianum sp. n., waynu sp. n., yunka sp. n.]. The two unidentified species of RIS [1918, Arch. Naturg. (A) 9: 1-197] are also discussed. All taxa are keyed (except *T. muzanum*), described and their characteristic features are illustrated. A complete list of synonyms and misapplied names is presented for every taxon. Notes on habitats are given, if known. The larva of *Teinopodagrion* is characterized on the basis of *T. venale* and *T. oscillans*, the latter of which is here described for the first time. The geographic distribution of all taxa is mapped. The monophyly of the Megapodagrion-complex, composed of the three genera, is shown on the basis of four synapomorphies in adult morphology, including two penis characters. The ground pattern -or groundplan- of the Megapodagrion-complex is reconstructed using 35 adult and three larval characters. The apomorphic character states are established through comparison with numerous megapodagrionid and other odonate taxa (outgroups). The three genera of the Megapodagrion-complex are equally related to each other, but Megapodagrion s. str. is the most autapomorphic. Penis morphology suggests a closer transpacific relationship of the Megapodagrion-complex with several argiolestine genera found in the Malayan and Australo-Papuan region, and a more remote relation with some genera present in Asia, Madagascar, West Africa, Central America and western South America. The three genera of the Megapodagrion-complex began to rise from a common ancestor probably in the late Cretaceous, while the recent species are of Oligocene/Miocene age. The evolution of Allopodagrion is thought to be related with the formation of the southeast Brazilian mountains, while the origin and speciation of Teinopodagrion was triggered by the Andean orogeny. Megapodagrion s. str. evolved in the large intracratonic basins which separate the Guyana from the Brazilian shield, and both from the Andes. Mapping of some key characters present in Teinopodagrion allows for recognition of a southern and a northern group of species. The presence amidst the northern group of a species morphologically referable to the southern group based on synapo-

morphies suggests repeated and independent local fixation of identical combinations of character states already present in a polymorphic ancestor, rather than colonizing events through migration out of a 'center of origin'. Ecologically the distribution of each of the three genera of the Megapodagrion-complex closely matches certain well-defined types of forest." (Author)] Address: De Marmels, J., Inst. Zool. Agricola, Fac. Agronomia, Univers. Central de Venezuela, Apdo. 4579, Maracay 2101, Edo. Aragua, Venezuela. E-mail: demarmjc@hotmail.com

2774. Dolný, A.; Teperova, E.; Volna, K. (2001): Dragonflies (Odonata) of the Nature Reserve Rajviz: current state, changes during the 20th century, conservation. Cas. slez. Muz. Opava (A) 50 (Suppl.): 66-77. (in Czech, with English summary). [The status of the 27 odonate species in the peat bog nature reserve in 1929-1932, 1949, 1950-1956, 1992, and 1998-2000 is compared and discussed. *Aeshna subarctica elisabethae*, *Somatochlora alpestris*, and *Leucorrhinia dubia* are of particular interest.] Address: Dolný, A., Katedra Biol. & Ekol., Ostravske Univ., ul. 30-dubna 22, CZ-70103 Ostrava, Czech Republic

2775. Dolný, A. (2001): The unusual occurrence of the dragonfly *Leucorrhinia pectoralis* (Odonata: Libellulidae) in the mining landscape in the town Karvina (Silesia, Czech Republic). Vázky 2001. Sborník referátu IV. celostátního semináře odonatologu, který se konal v Národním parku Sumava 2. - 5. 8. 2001. Seminár usporádali: ZO CSOP Vlasim, Správa NP Sumava, Správa. CHKO Blaník: 124-130. (in Czech with English summary). [*L. pectoralis* was found in the mining landscape in the town Karvina (49° 49.309'N, 18° 29.529'E, Silesia, Czech Republic). The bottom of the shallow pond (size 90 x 20 m, maximum depth of 90 cm) is muddy, only sporadically covered with stones and reminders of flooded woods. The locality is heavily influenced by human activities (building waste, dumps of mining deads, old tyres etc.). The dominant plant species *Typha latifolia* forms discontinuous growth in the pond. On 11.9.2001 chemical water parameters were: 7,42 pH, conductivity 1021 uS/cm. On 14.7.2001 10-20 males of *L. pectoralis* were accompanied by the following species: *Lestes viridis*, *L. sponsa*, *L. virens*, *Platycnemis pennipes*, *Coenagrion puella*, *Enallagma cyathigerum*, *Ischnura pumilio*, *I. elegans*, *Aeshna mixta*, *A. cyanea*, *A. grandis*,

Anax imperator, A. parthenope, Somatochlora metallica, Libellula depressa, L. quadrimaculata, Orthetrum cancellatum, O. albistylum, O. coerulescens, Symptetrum striolatum, S. vulgatum, S. sanguineum, and S. danae.] Address: Dolný, A., Katedra biologie a ekologie, Přírodovědecká fakulta Ostravské univerzity, Bráfova 7, 701 03, Ostrava 1, Czech Republic. E-mail: Alnes.Dolny@osu.cz

2779. Eidietis, L. (2001): Escape response of *Rana sylvatica* and *Rana clamitans* tadpoles. American Zoologist 41(6): 1641-1642. (in English). ["Predation of dragonfly larvae (*Anax junius*) on wood frog (*Rana sylvatica*) tadpoles was observed using standard and high-speed video. Typical predatory behavior of *A. junius* consists of stalking, extending the lower mouthparts, grasping the tadpole, and drawing it into the mouth. *A. junius* typically neither chase prey nor repeat strikes before tadpoles move out of range. *R. sylvatica* response to *A. junius* contact begins with curling into a tear-drop shape, followed by large-amplitude tail motions. Both curl and tail motions often rip *R. sylvatica* from the grasp of *A. junius*, at which point, the tail motions propel the tadpole. Green frog (*Rana clamitans*) tadpole response to poking were recorded and analyzed to ascertain whether tadpole escape behavior is caused by touch and to acquire multiple replicates of the response for analysis of kinematics. *R. clamitans* response to poking was similar to *R. sylvatica* response to *A. junius* strikes. The curl consisted of rotating the body around the center of mass while folding the tail towards the body. The amplitude of tail motions increased linearly with distance from the center of mass. A probabilistic model based on these descriptions of predation and escape behavior predicts that the performance of both the curl and the tail motions affects the probability of tadpoles surviving *A. junius* strikes. Increasing the rotational momentum of the point of contact would improve curl and tail motion performance. An empirically based model suggests that morphological changes induced by predators in *R. sylvatica* would serve to substantially increase the curl and tail motion performance, thereby increasing the probability of surviving a predatory strike." (Author)] Address: Eidietis, L., University of Michigan, Ann Arbor, MI, USA

2780. Ellenrieder, N. von (2001): Species composition and distribution patterns of the Argentinian Aeshnidae (Odonata: Anisoptera). Revista de la Sociedad Entomologica Argentina 60(1-4): 39-60. (in English). ["Ten genera and 27 species of Aeshnidae are recorded from Argentina: For each species a synonymy list and dist-

tribution data are provided, as well as diagnostic keys for adults and known larvae. Distribution data per biogeographic province in Argentina are compared through cluster analysis. Specific and generic distribution patterns show that the richest areas are those of the subtropical forests encompassed by the Paranaense and Yungas biogeographic provinces, and that there are no Subantarctic endemics within Aeshnidae. Cluster analysis and complementarity values show that the Aeshnidae assemblage of the Monte biogeographic province is more closely related to that of Prepuna, Patagonian and Subantarctic provinces than to that of the Guyano-Brazilian provinces, supporting the existence of an Andean-Patagonian domain as proposed by Ringuélet." 2782. Feng, Y.; Chen, X.-m.; Wang S.-.; Ye S.-d.; Chen Y. (2001): Three edible Odonata species and their nutritive value. Forest Research 14(4): 421-424. (in Chinese with English summary). ["Dragonflies are common insects distributed widely. Parts of their larvae are edible. The research results showed that there is custom of eating dragonfly larvae in many places of Yunnan. The common edible species are *Crocothemis servilia*, *Gomphus cuneatus*, and *Lestes praemorsa*. The larvae contain protein, fat, amino acids and microelements. The average contents of protein, fat and amino acids are 58.92%, 25.37% and 46.03% respectively. The content of 8 kinds amino acids necessary for human body is 16.41% in average, which accounts for 35.69% of the total amount of amino acids. The content of potassium, zinc, calcium and ferrum are 2 960 mg cntdotkg-1, 125.4 mgcntdotkg-1, 2 616.9 mgcntdotkg-1 and 796.2 mgcntdotkg-1. Therefore the dragonfly larva is one of nutritive edible insect resources."(Authors)] Address: Feng, Y., Research Institute of Resource Insects, CAF, Kunming, Yunnan, 650216 China

2783. Fet, V.; Bechly, G. (2001): Liochelidae, fam. nov. (Scorpiones): Proposed introduction as a substitute name for Ischnuridae Simon, 1879, as an alternative to the suggested emendment of Ischnurinae Fraser, 1957 (Insecta, Odonata) to Ischnurinae in order to remove homonymy. Bulletin of Zoological Nomenclature 58(4): 280-281. (in Chinese with English summary). ["The purpose of this application is to establish the new scorpion family name Liochelidae Fet & Bechly, 2001 (1879) as a substitute name for Ischnuridae Simon, 1879, which is a homonym of the widely used damselfly (Odonata) name Ischnurinae Fraser, 1957. In a previous application (BZN 57: 26-28) the authors proposed emending the latter name to Ischnurinae, but the introduction of Liochelidae avoids this undesirable change. The type genus of the Liochelidae is *Liocheles Sundevall*, 1833, which is in wide use as the valid senior synonym of the long abandoned name *Ischnurus* C.L. Koch, 1837 (the type genus of Ischnuridae Simon, 1879)." (Authors)] Address: Bechly, G., Staatliches Museum für Naturkunde, Abt. Paläontologie, Rosen-

stein 1, D-70191 Stuttgart, Germany. E-mail bechly@gmx.de

2787. Goffart, P.; Testaert, D.; Paquay, M. (2001): Actualisation du statut de l'Agrion de Mercure (*Coenagrion mercuriale*) dans la plaine de Focant (Beauraing). *Gomphus* 17(2): 83-94. (in French with English and Dutch summaries). ["Systematic surveys were conducted by means of transect-walk during the 2000 and 2001 seasons in order to estimate the current situation of *C. mercuriale* in the Focant floodplain and to compare it to those of the previous decades. The species has been found on 13 distinct zones, from which 11 were not known before, but the numbers were below 10 individuals in 7 of them. Two sectors only housed high level populations, with counts reaching nearly 100 and 500 individuals. The species has disappeared from 4 previously occupied zones and has severely declined in one other, facts which can be explained by negative habitat evolutions. If the species doesn't seem to be in the dangerous posture which could have been predicted from the mid nineties results, thanks maybe to better climatic conditions, its situation is not really safe and reassuring in the Focant area, where intensive agriculture still influence negatively aquatic habitats. Some tracks are suggested to conserve both the species and a certain level of farming." (Authors)] Address: Goffart, P., Unité d'Écologie et de Biogéographie, 5, Place Croix-du-Sud, B-1348 Louvain-la-Neuve, Belgium. E-mail: goffart@ecol.ucl.ac.be

2795. Hedström, I.; Sahlén, G. (2001): A key to the adult Costa Rican "helicopter" damselflies (Odonata: Pseudostigmatidae) with notes on their phenology and life zone preferences. *Revista de Biología Tropical* 49(3-4): 1037-1056. (in English). ["We present a key to the Costa Rican species of Pseudostigmatidae, comprising three genera with the following species: *Megaloprepus caerulatus*, *Mecistogaster linearis*, *M. modesta*, *M. ornata* and *Pseudostigma aberrans*. *Pseudostigma accedens*, which may occur in the region, is also included. For each species we give a brief account of morphology, phenology and life zone preferences, including distributional maps based on more than 270 records. These are not all of the known specimens from the area, but a high enough number to give a relatively good picture of the distribution and status of the species. We found *M. caerulatus* to be active during the first half of the year in seasonal, tropical semi-dry lowland forest and tropical moist forest at mid-elevation, but like *M. linearis*. *M. caerulatus* was active all year round in non-seasonal, tropical wet lowland forest and tropical moist forest at mid-elevation. *Mecistogaster modesta* also flew year round in non-seasonal, tropical wet lowland forest and tropical moist evergreen forest at mid-elevation, and likewise in seasonal and non-seasonal, tropical premontane moist forest. Only a few findings, however, have been made of *M. modesta* in seasonal, tropical semi-dry deciduous forest and seasonal, tropical moist evergreen forest. *Mecistogaster*

ornata was missing entirely from non-seasonal, tropical wet lowland forest and non-seasonal, tropical moist forest at mid-elevation, while this species was active year round in seasonal, tropical dry lowland forest and tropical semi-dry forest, as well as in seasonal, tropical moist evergreen forest and tropical premontane moist forest, both at mid-elevation. *Pseudostigma aberrans* has so far been found too few times in Costa Rica for any indication of flight time preference." (Authors)] Address: Sahlén, G., Systematic Zoology, Evolutionary Biology Centre, Uppsala University, Norbyvägen 18D, S-752 36 Uppsala, Sweden. E-mail: goran.sahlen@zoologi.uu.se

2796. Henry, J.D.; O'Carroll, D.C. (2001): What visual information do hawking dragonfly predators use to intercept prey? *American Zoologist* 41(6): 1470. (in English). ["Dragonflies are voracious predators that locate and intercept prey with astonishing accuracy. Many dragonflies (e.g. Corduliidae and Aeshnidae) are hawking predators, hunting while patrolling a territory. Dragonfly hunting is a visually guided behavior, utilizing large, highly acute eyes. Hawking dragonflies could use one or both of two mechanisms to extract visual information from their environment to determine prey location: (i) stereopsis and (ii) motion parallax. Stereopsis requires binocular overlap to determine object depth. Motion parallax uses relative image motion (due to motion of the viewer) to determine object distance; near objects will appear to move more quickly than far objects. Stereopsis would require an interneuron acting as a coincidence detector for movement in both halves of the small dorsal region of binocular overlap. Motion parallax would require integrating the output of two neurons that view the same region in space but are tuned to different velocities. To investigate which mechanism hawking dragonflies employ, we use intracellular recording and dye injection in the third optic ganglion (lobula) of Aeshnidae and Corduliidae. We find: (i) There are neurons that selectively respond to the motion of small targets. (ii) Neuroanatomical and physiological data indicate the presence of a binocular feature detecting neuron in the Corduliid *Hemicordulia tau*. (iii) There are at least three distinct classes of velocity tuning in target sensitive neurons (two classes have been found in Corduliids, three in Aeshnids). Data thus far support both models, indicating the potential for behavioral plasticity within the general strategy of being a hawking predator." (Authors)] Address: Henry, J.D., Univ Washington, Seattle, WA 98195 USA

CHKO Blaník: 79-108.* (in Czech with German and English summaries). [Between 1995 and 2001, 83 localities were surveyed for their odonate fauna. The faunistic data of 36 species is documented in detail. The results of the survey were compared with material collected prior 1995. In total 43 species are known from the district of Ceska Lipa.] Address: Honcu, M.;

Okrewsni vlastivedné muzeum, námesti Osvobození 297, 47001 Ceska Lipa, Czech Republic

2803. Hori, S.; Yokoyama, T. (2001): Record of two species at Noboro Forest Park. *Bulletin of The Hokkaido Odonatological Society* 13: 11-12. (in Japanese). [*Mnais pruinosa costalis*, *Davidius moiwanus*] Address: Yokoyama, T., 1-15-303, Higashi 22chome, Kita 19jo, Higashi-ku, Sapporo City, 065, Japan

2804. Karube, H. (2001): On the endangered species of *Sympetrum maculata* Oguma. *Nature & Insects* 36(7): 14-16. (in Japanese). [Introduction: Nearly unnoticed, *S. maculatum* turned out to be one of the most endangered species in Japan. It is indigenous to Japan, and recorded from 17 prefectures of the southern part of the northeastern district to the Chugoku region of Japan. It inhabits clean and shallow reservoirs mainly to the west of central Japan, and highland bogs located close to the Sea of Japan. Due to reports of a significant decrease of the species, it was assessed as endangered in Hyogo Prefecture (Aoki and Azuma, 1998). When, in spring 1999, we collected information on endangered species from all over the country to revise the RDB of the Environment Agency, we found the species in critical condition: only less than 30 habitats could be traced in Japan. This situation contrasts with the fact, that it was not listed as an endangered species in the RDB of 1991, and was not designated as a rare species. The current survey of the species results as follows: Situation: *S. maculata* is known from 30 habitats in 10 prefectures; it is extirpated from 7 prefectures. Most of the habitats are in a critical condition, and especially the habitats to the west of the Japanese mainland sharply decreased. Most habitats are isolated with distances of about 50 to 100 km to the next habitat. In 2000, in Hyogo Prefecture, all habitats seem to be lost. Causes of decrease: It inhabits natural habitats which are easily developed. The factors are as follows; No. 1: reclamation of reservoirs and bank protection works; No. 2: aridity of bogs and growth of reeds; No. 3: drought damage in 1994 and 1995; No. 4: Changes of environment of the habitats; No. 5: chemical spraying to rid pine weevils; No. 6; water pollution; No. 7: Change of management of reservoirs, e.g.; non drainage of water in winter. Also the character of persistency to special environment accelerate the decrease. Oviposition sites are situated in bogs of low grasses, and shallow ponds, therefore the habitats are often damaged by drought. In addition, *S. maculata* is endangered by black bass. Habitat environment: The investigated habitats - wet land with low grasses - were characterised in most cases by clean and rather acid water. Ecology: Most *Sympetrum* species including this species are active from morning till noon. In the region near the Sea of Japan, I found that species active at the edges of water bodies on cloudy or rainy days as long as the ambient temperature was high. The time of activity and ecology differed between the populations near the Sea of Japan and in central Japan. In the latter the species was not active in the unfavorable weather. Prospect of protection: I think this species should be designated as Endangered species for the RDB List. Furthermore we need to investigate the known habitats and new habitats and notify the habitats to governments and promote the preparation of conservation action plans. 2805. Kazunobu, K. (2001): The deteriorating situation of the Endangered *Copera tokyoensis* Asahina in Japan. *Nature & Insects* 36 (7): 10-13. (in Japanese). [Introduction: *Copera tokyoensis* Asahina was designated as a Critically Endangered species (CR+EN) in Red Data Book by Ministry of the Environment in April, 2000. The committee of nature conservation of The Japanese Society for Odonatology decided to conduct a long term investigation of the situations of the damselfly and to collect information about it including other endangered species from 2000. As I am the organizer of the division of *Copera tokyoensis* Asahina and *Cercion plagiolum* (Needham) of the committee, I studied the situations of the species in the recorded localities. Here I report the data and an example of the action for conservation of the species. Also I expect readers to contribute to us information on the species.]

Distribution: In the genus *Copera* Kirby, 8 species and 7 subspecies have been recorded from all over the world, and from Japan only two, the species and *C. annulata* were recorded. This damselfly was discovered in the northeastern Tokyo by Ishikura, Hideji in 1936, and named as a new species by Dr. Asahina, Syojiro in 1948. Its zoological name *tokyoensis* was named after the locality of the discovery: Tokyo (Koaidame at Kanamachi). *C. annulata* and *C. ciliata* are the closely related species of the damselfly. *C. annulata* is widely distributed at ponds and marshes surrounded by forests in the lowlands in Japan from Hokkaido, Honshu: the mainland of Japan, Shikoku and Kyushu, and in China. While *C. tokyoensis* is limitedly distributed wide and open ponds, of which vegetation are reed and Indian rice, along the main and branch streams of the Tone River in the Kanto plains, the lower reaches of the Shinano River in Niigata Pref., and in Miyagi Pref. In abroad it was recorded from Seoul in South Korea and the Yangtze Basin. It has not been cleared yet why the damselfly is isolatedly distributed, however, in the ice age when the regression advanced, the main river of Japan and the Yangtze River were said to be connected, and this species might have been distributed the lower reaches of the old Yangtze River. Thereafter the rivers were separated by the transgression, and in Japan it has been reliclike distributed to the well developed deltas of the Tone and the Shinano. 2. Flying season and body size: The flying season of the species is from mid May to the end of September, its peak is August. The latest record was October 10, 1975 at Yagyū, Kitakawabe-cho, Saitama Pref. As the season advances the body size becomes smaller. The individuals emerges in mid and late August are considered as the second generation for the year. 3. Behaviour of adult: The behaviour of immature adults is not so different from *C. annulata*. The damselflies perch low on leaves or stems of grasses at the water edges of reed and Indian rice, or open spaces by trampled down. They did not move long distance, at longest within 10 meters, and rest in the shade at the edges of forests. They reproduce after the rainy season. They oviposit in tandem endophytically into tissues of water plants. At the time males of the species often stand upright with the prothorax of the female grasped by the appendage of the male. The substrate of oviposition is submerged plants, or rotten leaves and stems drifting on the surface of water. 4. Intermediate form: The distributions of both species overlap each other, but they do not rarely inhabit the same water body (only a few areas in the Kanto district). Many intermediate form of individuals had been recorded

from Sakata Marsh, Gunma Pref., the Lake Semba, Ibaraki Pref., Amidase Pond, and Junsai Pond, Niigata Pref., etc. and these are necessary to be investigated the possibility of the hybrid with *C. annulata*. 5. Localities: This damselfly has been recorded from 135 localities since 1952, however, only 22 localities are left for these 3 years. Only two (from Niigata and Ibaraki, respectively) are newly found for the three years. The past localities are as follows; Chiba (45), Ibaraki (25), Saitama (25), Gunma (19) and Niigata (12), among them in Chiba and Gunma the numbers decreased sharply and in these areas conservation plan should be formed. 6. Problems for conservation: Most of the localities distributed in the delta areas and these are likely to be reclaimed for residential areas, and the waters are polluted by domestic waste and eutrophication. Also the damselfies are being endangered by secret release of black bass. Now these ponds are aged and accumulated by sludge, which prevents growth of water plants, and consequently oviposition substrates of the damselfly are lost which lastly causes it to extinction. At isolated areas in such circumstances, the dragonfly is driven to extinction because of lack of dispersibility. Here I introduce an example of action for conservation at Hakidashi-numa in Noda City, Chiba Pref. The area belong to an inundated region of the Tone River, where many farming reservoirs had been distributed. In the pond, which is 400 meters around, spring water wells up and 23 species including *C. tokyoensis* inhabit. The local action of conserving the pond started in 1996. The pond was leased by the city government, and eight local volunteers groups organized a conservation union of Noda and are managing actions; watch of illegal dumping of waste, mowing of weeds and grasses, investigation of fluctuation of specified species and forbidding of anglers into the pond, etc. 7. Prospect: These endangered species are necessary to be notified well to people. The conservation should not be limited only to the specified species and specified areas but more widened in cooperation with governments, citizens and NPO, who discuss each other and consult experts. 2808. Knijf, G. De (2001): Observation of *Leucorrhinia rubicunda* (Linnaeus, 1758) at the 'Kraaibos' in Moen-Zwevegem (Province of West-Flanders). *Gomphus*

17(2): 75-82. (in Dutch with English and French summaries). [29 May, 2001, two adult males of *L. rubicunda* were observed at the Kraaibos, Belgium. "This is the first observation of the species for this most western province of Belgium and the first observation after more than 70 years outside their distribution area in Flanders. The habitat, especially clay soils, is aberrant from the other sites in Belgium and doesn't correspond with the literature. The nearest Belgian populations of *L. rubicunda* are located more than 100 km away from the 'Kraaibos'. Very remarkable are the observations of three adult males on three different localities since 1998 in adjacent northern France, where the species was considered as extinct. Suitable habitat seems to be still present there and it is very likely that there are locally some populations present." (Author)] Address: Knijf, G. de, Instituut v. Natuurbehoud, Kliniekstraat 25, B-1070 Brussel, Belgium. E-mail: geert.de.knijf@instnat.be

2809. Kurashina, H.; Kikuya, N. (2001): A study of the decreasing cause of *Libellula angelina*. *Nature & Insects* 36 (7): 5-9. (in Japanese). [In 1969, habitats of *Libellula angelina* were spread from the northern Miyagi Prefecture to Kagoshima Prefecture, mostly in Honshu, the main Island of Japan, however in 2000, only 3 habitats remained in Honshu. The species also occurs in Kyushu except Oita Prefecture and Kagoshima Prefecture, the rest of the habitats are in an extremely critical condition. We studied distribution, ecology, behaviour and fluctuation of populations of *L. angelina*, particularly in Oita since 1993. In 1997, *L. angelina* was found at nine localities in Oita Prefecture. These habitats are all in a critical, unpreferable condition. Reasons of the decline of *L. angelina* are discussed as follows. 1. The first stage of extinction: In general, *L. angelina* inhabits shallow habitats within reservoirs in the rice farming area of the lowlands along the coast. Reservoirs were depreciated recently because of large scale irrigation works, reclamation of farm land for road construction, development of residential areas and factories, or reduction of rice cultivation acreage. Consequently most of the reservoirs were reclaimed and disappeared. Thus, habitat loss is a serious reason for the declining populations of *L. angelina*. Also agricultural chemicals which came into wide use since the latter half of 1950s affected the decrease of the dragonfly. Insecticides affected preys as well as predators. *L. angelina* is more sensitive to chemicals than other odonata. This can be concluded by the fact that imagines could be observed at ponds polluted by waste water of farming and domestic waste, but never reproduced there. 2. The second stage of extinction: In spite of the the habitat loss and habitat depreciation, a few populations of the species survived at isolated localities. In these habitats the dragonfly is endangered by drought, aridity, and introduced species like black bass, bullfrog, carp and crayfish, and especially technical maintainance of reservoirs. After emergence, most of the individuals of *L. angelina* don't disperse and stay in "its habitat". 90-95% of a local population are estimated to be philopatric. This increase the risk of local extincting (e.g. by habitat loss) significantly. Populations in (newly settled?) habitats in large reclaimed areas near the seashores, were given up soon. This could be due to genetic isolation and lack in diversity of gene. Therefore the adaptability to the environment of the species may be low and the population can not be stable. 3. Conditions in the stable populations: Now isolated populations were extinguished one after another. Though isolated, a population in Imuta Pond at Ketoin-

cho, Kagoshima Pref., could kept be stable by optimization habitat management system. 4. Hypothesis of sub population: We define a 'sub population' as the population that belongs to the same habitat population but differs in the emergence and reproductive site. In a large bog, there exist several sub population, and this may enable the genetic diversity of the species to enhance. At Noishin-ike 1000 to 2000 individuals occurred every year since 1994. Therefore populations of Noishin-ike or Imuta-ike might be kept stable by steady environment and sub populations, which must enhance steady genetic diversity. Translation Ishizwawa, Naoya. (2001): Nestling diet and prey selection of the Japanese Wagtail *Motacilla grandis*. *Journal of the Yamashina Institute for Ornithology* 33(1): 36-43. (in English with Japanese summary). ["Nestling diet of Japanese Wagtails (*Motacilla grandis*) was investigated by the neck ligation method and compared with the food availability in their feeding habitat during the breeding season of 1999 in Higashi Hiroshima, western Japan. Nestling diet comprised of 85.5% insects, 14.2% arachnids and 0.3% chilopods in individual number basis. Odonata order comprised nearly one-fourth of the diet in dry weight basis. Diptera, Lepidoptera, Coleoptera, Orthoptera and Arachnida were also important contributors to the total prey weight. Chironomidae and Ephemeroptera families were the most numerous prey items but their contribution to the total prey weight was small. Electivity indices indicated that the Japanese Wagtail prefer certain prey items (*Libellulidae*, *Tipulidae*, *Dytiscidae*) when collecting prey for the nestlings." 2814. Martin, D.C.; Neely, R.K. (2001): Benthic macroinvertebrate response to sedimentation in a *Typha angustifolia* L. wetland. *Wetlands Ecology & Management* 9(5): 441-454. (in English). ["Fiberglass mesh enclosures (1 X 1 m²) in a *Typha angustifolia* L. marsh were employed to examine the effects of clay additions on the resident macroinvertebrate communities. Total invertebrate density, insect density, and number of insect families decreased significantly by 33%, 37%, and 17%, respectively, in enclosures receiving sediment. More specifically, incoming clay adversely affected densities of Coleoptera larvae, Diptera larvae, Megaloptera larvae, Odonata larvae, Pelecyptoda, and Gastropoda. Densities of specific families within the Diptera (larvae) and Coleoptera were also affected; Dolichopodidae, Stratiomyidae, Hydrophilidae, Tabanidae, Dytiscidae adults, and Scirtidae larvae decreased significantly in numbers in sedimented enclosures. In contrast, the effect of sedimentation on Carabidae (adults and larvae) and Dytiscidae larval densities varied significantly with time, whereby densities were higher in the sedimented treatment only for the initial two months of the study. Densities of predator-engulfer, collector-filterer, and scraper feeding groups were reduced in sedimented plots by 28%, 44%, and 27%, respectively. Significant short- and long-term increases in turbidity and suspended solids in enclosures treated with clay, as well as sediment deposition, were probably responsible for changes in the invertebrate communities." 2815. Matsuki, K. (2001): Threatened dragonfly species in Japan. Part II. *Nature & Insects* 36 (7): 2-4. (in Japanese). [This number is a sequel to the articles "Threatened dragonflies" *Nature & Insects* Vol.33, No. 10, October, 1998. Thereafter the revised list of Red Data Book (RDB) was published by the Environment Agency (from the start of the fiscal year, April, 2001 its name was changed to Ministry of the Environment) in March, 2000. In order to cope with the revision, the committee of nature conservation of The Japanese Society for Odonatology set up new sections, and started collection of information. Last year the problem of black bass (large mouth bass) became a subject of discussion abruptly. For these years, RDB of prefectures have been published, and some of them are under the first revision. 1. Revision of RDB and the change of the criteria. For these ten years, the habitat environment of Odonata has been worsened heavily, and Odonata decreased sharply, especially lentic Odonata. (1) Endangered species of Odonata increased from two in RDB of 1991 to 10 in RDB of 2000, and the Vulnerable species, which is the Endangered species in the old category, increased from one to ten (Table 1). (2) Five rare species of Odonata of

re species of Odonata of the Ogasawara Islands were designated as Endangered species: *Indolestes boninensis* and *Hemicordulia ogasawarensis*; Vulnerable species: *Boninagrion ezoin*, *Rhinocypha ogasawarensis* and *Boninthemis insularis*. The revised Red List of Odonata was taken charge of by the committee of nature conservation of The Japanese Society for Odonatology based upon the quantitative data during these ten years, and 38 species and one local population were listed and included around 20% of Japanese fauna of Odonata. 2. Actions of The Japanese Society for Odonatology. As the Red List of Endangered species and Vulnerable species of RDB increased, we set up the new special sections for *Sympetrum maculatum*, *Orthetrum poecilops miyajimensis*, *Cercion plagiosum*, *Copera tokyoensis*, *Sympetrum uniforme*, *Lestes japonicus*, *Coenagrion hylas*, *Leucorrhinia intermedia ijimai*, *Macromia daimoji*, *Rhyothemis severini*, Indigenous species of Ogasawara Islands and Okinawa and local populations, and collect information and literature on them. But our staff for the sections is not enough, and we give priority over the Endangered species and Vulnerable species. The sections of *Libellula angelina* and *Mortnagrion Hirosei* accumulated so much information for these several years, and appealed conservation of the species to local governments and provided local citizens with useful information. It was reported that Fisheries Agency was reconsidering the administration policy and relaxing fishing rights of black bass, enlarging the licensed areas of the fish. This means change of policy by the agency to habitat segregation of the fish. For fear that the predation pressure by the fish may cause reduction of the local dragonfly fauna or extinction of the designated species from all over Japan, we requested the Minister of Agriculture, Forestry and Fisheries, Director General of Fisheries, prefectural governors and prefectural committees of administration of fresh-water fisheries not to enlarge the licensed areas of the fish in corporation with The Ichthyological Society of Japan and The Japanese society of Coleopterology. We, President Eda, Vice-president Inoue and Secretary Karube visited Director General of Fisheries and explained foreign and domestic examples of predation on Odonata by black bass and professed opposition to the Fisheries' Plan. According to a report from Niigata Prefecture, black bass preyed on adult dragonflies as well as larvae in the water; from stomach contents of nine black bass about 70 dragonflies were found. We set up the countermeasure section of foreign fish, such as black bass or bluegill. 3. Problems of Prefectural RDB and the prospect. Obscure criteria of data collection(1), ranking(2) and attitude for conservation(3).

Natn. Hist. Nat., 45 rue Buffon, F-75005 Paris, France. E-mail: anel@cimrs1.mnhn.fr

2825. Ortaz, M. (2001): Diet seasonality and food overlap among fishes of the upper Orituco stream, northern Venezuela. *Revista de Biología Tropical* 49(1): 191-197. (in English with Spanish summary). [The diet of four diurnal fish species (*Creagrutus bolivari*, *Knodus deuterodonoides*, *Knodus* sp. and *Poecilia reticulata*) from the Orituco stream at northern Venezuela include also Odonata. Address: Ortaz, M., Instituto de Biología Experimental, Universidad Central de Venezuela, Caracas, 1041, Venezuela. E-Mail: capricorniomvos@star-media.com

2826. Pathak, S.C.; Choubey, A.K.; Kulshrestha, V. (2001): Biodiversity of insects trapped over Bay of Bengal. *Entomon* 26(3-4): 211-226. (in English). [Wind borne insects of terrestrial origin in the aeolian environment over Bay of Bengal were trapped using multinet trapping system aboard the Ocean going Research Vessel (ORV), Sagar Kanya. Insects trapped belonged to eleven orders of which four viz., Hemiptera (94%), Diptera (4%), Hymenoptera (1%) and Coleoptera (0.5%) accounted for almost 99% of the total haul of 16429 in two traps with three nets in each, operated continuously for the duration of the cruise. Trichoptera, Neuroptera, Thysanoptera, Odonata and Dictyoptera were represented by single digit numbers.] Address: Pathak, S.C., Rani Durgavati Univ, Dept Biol Sci, Jabalpur 482001, India

2827. Pinratana, A. (2001): Editorial. *Malangpo* 18: 163. (in English). [Brief introduction into more recent odonate collecting activities in Thailand, and a short note on increasing interest in odonatology in Thailand.] Address: Pinratana, Bro Amnuay, Saint Gabriel's College, Bangkok 10300, Thailand

2828. Pliúraitė, V. (2001): The seasonal change of macrozoobenthos is the Merkys river in 1998. *Acta zool. lituan.* 11(1): 39-52. (in English with Lithuanian summary). [Information are given on seasonal dynamics, abundance and biomass in various habitats of the Merkys River, Lithuania. These data refer to "*Odonata*", while *Calopteryx splendens* and *Gomphus vulgatissimus* are listed in the 1998 taxa list of Merky River.] Address: Pliúraitė, V., Inst. Ecol., Akademijos 2, 2600 Vilnius, Lithuania

2829. Prot, J.-M. (2001): Atlas commenté des insectes de France-Comté. Odonates. Office pour l'information eco-entomologique de France-Comté: 185 pp. (in French). [This atlas covers records of Odonata from a region (including 3 Départements) in eastern France situated to the western border of Switzerland and - partly - Germany. This information may be of some interest to stimulate vigilance of odonatologists for some species to be expected under the amendments of global climate: it is fascinating to see that *Boyeria irene* reaches the latitude of Basel. 63 species - regularly reproducing in the region - are presented in detail: each monograph contains information on the habitat and habits, distribution, phenology, status, and comments. The species are documented by colour photographs (exception *Sympetrum sanguineum*), a graph with flight season, and two maps (records per UTM, numbers of observations plotted against locality and altitude). In addition, 16 species probably to occur in the region or to be expected in near future, and species with questionable status are commented. Some introductory chapters with information on history, development of inventarisation of the species, geography, a bibliography, a list of species and their current status specified for each Département and the town of Belfort complete this very interesting atlas. It is fascinating to observe the development of the atlas project of the French odonatologists. Obviously (compare OAS 2887), they have reached the level of regionalised maps with plenty of highly welcome information.] Address: Insectarium - Muséum d'histoire naturelle, La Citadelle, F-25000 Besançon, France. OPIE-Fcomte@wanadoo.fr

2830. Ramos-Elorduy, B.J.; Pino Moreno, J.M. (2001): Insectos comestibles de Hidalgo, Mexico. *Anales del Instituto de Biología Universidad Nacional Autónoma de México Serie Zoología* 72(1): 43-84. (in Spanish with English summary). [99 species of edible insects in Hidalgo, Mexico include 12 orders: Hymenoptera (35 species), Hemiptera (15 species), Lepidoptera (15 species), Coleoptera (15 species), Trichoptera (four species), Orthoptera (five species), Diptera (four species), Ephemeroptera (two species) and Odonata, Isoptera, Homoptera and Neuroptera with one species each. Regional distribution, consumption period and the way to fix, preserve and commercialize them, are discussed.] Address: Ramos-Elorduy B Julieta, Instituto de Biología, UNAM, 04510, Mexico, D.F. Mexico

2831. Reeves, D. (2001): From the president et al.. *Austrolestes* 2: 1-4. (in English). [D. Reeves introduces into some current activities in Australian odonatology (preparation of identification keys for larvae by Günther Theischinger, activities of the society), reviews Jill Silsbys book "*Dragonflies of the World*", and answers "Frequently asked questions".] Address: Reeves, D., 30 Bramston Tce, Herston, QLD 4006, Australia. E-mail: denissreeves@uq.net.au

2832. Reeves, D. (2001): Roma street wetlands. *Austrolestes* 2: 2. (in English). [Australia; 13 odonate species were recorded in a newly created water body.] Address: Reeves, D., 30 Bramston Tce, Herston, QLD 4006, Australia. E-mail: denissreeves@uq.net.au

2833. Reeves, D. (2001): Species profile: S-e Queensland's "Giant Dragonfly" - *Petalura litorea* Theischinger. *Austrolestes* 2: 3-4. (in English). [Habits and the habitat of the species are briefly outlined. Special

emphasize is given to the legal conservation status of the species. In addition, the rest of the taxa of the genus *Petalura* are briefly discussed.] Address: Reeves, D., 30 Bramston Tce, Herston, QLD 4006, Australia. E-mail: denissreeves@uq.net.au

2834. Rumpf, M.; Wernicke, P. (2001): Die Libellenfauna ausgewählter Gewässer im Naturpark Feldberger Seenlandschaft. Natur und Naturschutz in Mecklenburg-Vorpommern 36: 92-109. (in German with English summary). [Mecklenburg-Vorpommern, Germany; in 1998 and 1999, 45 water bodies (in most cases lakes, and a few running waters) were surveyed for their odonate fauna. Along with detailed data on morphology and chemistry, the Odonata are documented for each of the water bodies. 48 species could be traced; considering literature data, a total of 55 species is known from the region. The lake with highest diversity (31 species) is the dystrophic Mummelsee, a shallow, temporarily drying out water body with a surface of app. 1-2 ha only. Five species of the genus *Leucorrhinia* make the region to an odonatological hot spot in Europe; the occurrence of "lake-populations" of *Onychogomphus forcipatus* and *Gomphus vulgatissimus* is of special interest. 23 species are discussed in some detail.] Address: Rumpf, M., Blumenstr. 13, D-17268 Warthe, Germany

2835. Salamanca-Ocana, J.C.; Cano-Villegas, F.; Ferreras-Romero, M., (2001): Contribution al conocimiento de la distribución ibérica actual de *Onychogomphus costae* Selys, 1885 (Odonata: Gomphidae). Boln Asoc. esp. Ent. 25(1/2): 187-188. (in Spain with English title). ["The published records are reviewed and annotated, and records from Palma de Rio and Cordoba (V/VI-2000) are added."] Address: Ferreras-Romero, M., Departamento de Biología Animal (Zoología), Facultad de Ciencias, Universidad de Córdoba, Avda. San Alberto Magno s/n, E-14004 Córdoba, Spain. E-mail: ferreras@teleline.es

2836. Schilder, R.J.; Marden, J.H. (2001): Workloop force and lever arm length allometry in dragonfly flight motors. American Zoologist 41(6): 1651. (in English). ["Maximum isometric muscle force production scales as muscle mass^{2/3}, whereas maximum net force output by flying animals scales isometrically with total flight muscle mass. What causes this transition between the two scaling relations? We examined this question by subjecting dragonfly flight muscles to contraction regimes (workloops) that simulated working conditions of the muscle during maximum load lifting. Our hypothesis is that a combination of allometric (rather than isometric) scaling of average net muscle force output and the ratio of lever arm lengths (i.e. mechanical advantage) in the muscle-to-wingtip mechanical linkage is sufficient to account for the observed transition from muscle mass^{2/3} scaling to the isometric scaling. We found that 1) maximum isometric force scales as muscle mass^{0.67}, 2) maximum net force production during load lifting (F₂) scales as total flight muscle mass^{1.067} (M_{1.067}), 3) workloop average net force output (F₁) scales as muscle mass^{0.86} (M_{0.86}), 4) muscle fulcrum-lever arm length (d₁) scales as muscle mass^{0.54} (M_{0.54}), and 5) fulcrum-wingtip length (d₂) scales as muscle mass^{0.33} (M_{0.33}). Since moments are conserved on either side of a fulcrum (F₁*d₁=F₂*d₂), maximum net force output by the muscle-wing system (F₂) should scale as: M_{0.86}*(M_{0.54}/M_{0.33})=M_{1.07}, which agrees well with the observed scaling (M_{1.067}) in this study and previ-

ous load lifting experiments on dragonflies and other flying animals." (Authors)] Address: Marden, J.H., Dept Biol., Pennsylvania St. University, 208 Mueller Laboratory, University Park, PA 16802, USA

2837. Schmidt, E. (2001): Der Plattbauch *Platetrum depressum* (L., 1758), (Odonata), das Insekt des Jahres 2001. Entomologische Nachrichten und Berichte 45(1): 1-8. (in German with English summary). ["It is the type species of *Platetrum* NEWMAN, 1833, which within the *Libellula*-group is based on the prominent bifurcate process at 1st sternum. It is part of the secondary copulatory apparatus at sterna 2/3 and forms a good autapomorphy at genus level. Thus North American *Platetrum* HAGEN, 1861 became the nearctic subgenus of *Platetrum*, including *P. lydia* (DRURY, 1770), the Common Whitetail." This finding coincides with that of Carle & Kjer (2002), see OAS 2902. "The biology/ecology in Central Europe are summed up. They are interpreted as adaptations to settle in open wetlands in natural river landscapes of the plains, which today are devastated in most parts of Germany. Nowadays the species here breeds usually only in man made habitats in the pioneer stage (like shallow drying up pools or gravel pits), which requires a special habitat management." (Author)] Address: Schmidt, E., Biologie und ihre Didaktik, FB9/S05, Universität GH Essen, D-45117 Essen, Germany

2838. Schupp, D.; Behm-Berkelmann, K.; Herrmann, T.; Pilgrim, B.; Schacherer, A. (2001): Arten brauchen Daten - Erfassung von Tier- und Pflanzenarten in Niedersachsen. Informationsdienst Naturschutz Niedersachsen 5/2001: 210-239. (in German). [This introductory manual for the species mapping scheme of the Federal State Niedersachsen in Germany refers on pages 230-231 on Odonata. Detailed instructions on mapping have to be taken from Herrmann et al. (see OAS 2797)] Address: Niedersächsisches Landesamt für Ökologie, Abt. Naturschutz, Postfach 101062, D-31110 Hildesheim, Germany. www.nloe.de

2839. Seidenbusch, R. (2001): Die Gefährdung der Libellen im Landkreis Amberg-Sulzbach. Eisengau 16: 5-16. (in German). [Amberg-Sulzbach district, Bavaria, Germany; 53 species are listed, and the status of the various aquatic habitats in the region is outlined.] Address: Seidenbusch, R., Klenze Str. 5, D-92237 Sulzbach-Rosenberg, Germany

2840. Sformo, T.T.S. (2001): Minimum flight temperature and thermoregulatory performance of sub-arctic dragonflies. American Zoologist 41(6) : 1584-1585. (in English). ["Sub-arctic dragonflies (Odonata: Anisoptera), an order of insect previously not studied in Alaska, provide a unique system with which to examine questions of thermal biology. Two potential adaptations are the ability to initiate flight at low temperature and to thermoregulate. To establish minimum flight temperatures, I record the lowest temperature at which a species can maintain level flight, both in the lab and in the field. To determine thermoregulating ability, I measure thoracic temperature (T_{th}) of individual dragonflies using a thermocouple. T_{th} is then compared to the dragonfly model providing the operative environmental temperature (T_e). By regressing T_{th} on T_e, the slope of the regression line indicates thermoregulatory ability (Thermoregulation Performance Index). I predict that northern dragonflies will have lower minimum flight temperatures

than comparable species from lower latitudes. I also predict a general pattern wherein more massive species are able to thermoregulate by both physiological and behavioral means, while less massive species rely solely on behavioral repositioning. The relationship between T_{th} of living specimens and T_e is examined for each species and compared across species to examine relative thermoregulating ability. I show, contrary to speculation by Vogt and Heinrich (1983), that minimum flight temperature of northern dragonflies are not different from comparable species from Maine, although they differ from species in Florida. Minimum temperatures range from 14°C for *S. danae* to 22°C for aeshnids. Finally, I conclude that the relative thermoregulating ability is a function of mass, which ranges from 0.09g for the least to 0.86g for the most massive, while the Thermoregulatory Performance Index ranges from 0.90 (a thermal conformer) to 0.14 (a thermal regulator), respectively. (Author)] Address: Sformo, T.T S., University of Alaska Fairbanks, Fairbanks, AK USA.

2841. Sharifi, M.; Hemmati, Z. (2001): Food of Mehely's horseshoe bat *Rhinolophus mehelyi* in a maternity colony in western Iran. *Myotis* 39: 17-20. (in English). ["The diet of *R. mehelyi* was investigated from droppings collected in spring and summer 2000 in a maternity roost in Killasefid cave, west-central Zagros Mts. Moths (Lepidoptera) dominated in the food (68-97% of volume), being followed by beetles (Coleoptera, 3-29%) and flies (Diptera, 0.1-1.3). Other prey included Odonata, Neuroptera, Homoptera, Hemiptera, Trichoptera, Dictyoptera and Acarina. Prey diversity declined sharply from April/May to June/July." (Author)] Address: Sharifi, M., Dept of Biology, Faculty of Science, Razi University, Kermanshah, Baghabrisham, 67149, Iran. E-Mail: msharifi@razi.ac.ir

2842. Síbl, J.; Seginkova, A. (2001): Contribution to the knowledge of dragonflies (Insecta: Odonata) of national nature reserve Súr fen and its surrounding (southwestern Slovakia). *Entomofauna carpathica* 13: 5-9. (in Slovakian, with English summary). [In 1999 and 2000, 31 dragonfly species have been recorded at 5 localities of the National Nature Reserve "Súr fen" and its surroundings (situated in southwestern Slovakia). The present number of species - including literature records - now amounts to 40. The occurrence of several dragonfly species, which are considered rare in the Slovak Republic, was confirmed, e.g. *Orthetrum coerulescens*. 11 species (*Brachytron pratense*, *Anaciaeschna isosceles*, *Anax imperator*, *A. parthenope*, *Orthetrum albistylum*, *O. coerulescens*, *Libellula quadrimaculata*, *Crocothemis erythraea*, *Cordulia aenea*, *Sympetrum danae*, *S. meridionale*) were recorded for the first time in the study area. The species are grouped to three dragonfly communities following the system of Jacob (1969): Gomphus - *Calopteryx splendens*, *Erythromma* - *Anax imperator*, *Lestes-Sympetrum* - *Aeshna mixta* and *Orthetrum* - *Libellula depressa*.] Address: Síbl, J., J. Stanislava 15, SK 84105 Bratislava, Slovakia

2843. Síbl, J. (2001): On the distribution of *Leucorrhinia pectoralis* (Odonata: Libellulidae) in western Slovakia. *Entomofauna carpathica* 13: 3-4. (in Slovakian, with English summary). [The red listed *L. pectoralis* is considered rare in the Slovak Republic; it was confirmed recently in western Slovakia within 2 geomorphological units at 10 localities for the first time.] Address: Síbl, J., J. Stanislava 15, SK 84105 Bratislava, Slovakia

2844. Song, D.; Wang, H.; Zeng, L.; Yin, C. (2001): Measuring the camber deformation of a dragonfly wing using projected comb fringe. *Review of Scientific Instruments* 72(5): 2450-2454. [This is a contribution about non-contact methods of measuring wing deformation patterns.] Address: unknown.

2845. Sprandel, G.L. (2001): Fall dragonfly (Odonata) and butterfly (Lepidoptera) migration at St. Joseph Peninsula, Gulf County, Florida. *Florida Entomologist* 84(2): 234-238. (in English). [The author describes the fall 1999 migration of 5 Lepidoptera and 4 Odonata species north along St. Joseph Peninsula, Gulf County, in the Florida Panhandle. The Gulf fritillary butterfly (*Agraulis vanillae* (L.), Lepidoptera: Nymphalidae) accounted for 58% of the insects counted; the highest rate was 3,162/h, with an estimate of total season migration of over 250000 individuals. *Anax junius* was the next most common with a maximum rate of 3,297/h, and with an estimate of total season migration of app. 78000 individuals. "The median and peak period for these two species was the first week in October. The observed flight pattern may demonstrate a reluctance to cross open water." In tab. 1 the migration levels of all dragonflies and butterflies incl. *Tramea lacerata* (3.3% / app. 21000 ind.), *Pantala flavescens* (1.8% / app. 9000 ind.), and *Tramea carolina* (1% / app. 4700 ind.) are documented. Additional information of preying of *A. junius* on insects, road traffic mortality, flying in tandem, and flight high should be noted.] Address: Sprandel, G.L., Florida Fish & Wildlife Conservation Commission, 620 Meridan St., Tallahassee, FL 32399 USA

2846. Terzani, F.; Carletti, B. (2001): Descrizione di *Pseudagrion bernardi* spec. nov. della Repubblica del Congo (Odonata: Coenagrionidae). *Opusc. zool. flum.* 199: 7-12. (in Italian with English summary). ["The new species is described and illustrated, and its affinities with *P. kibalense* Longfield, 1959, *P. symoensii* Pinhey, 1967, and *P. fisheri* Pinhey, 1961 are discussed. Holotype male and allotype female; Republic of Congo: Kintele, 6-XI-1978; deposited at MZUF, Firenze. Paratypes of both sexes from Djili (VI-1978, XII-1979, XI-1980), Kintele (V, VI, 6-XI-1978, 5-1, II, III, XII-1980), Loufula (1-1980), Makabana (X-1980), Voka (1-1980) and Dimonika (VI-1980)." 2854. Waldhauser, M. (2001): The current state of knowledge about dragonflies (Odonata) research in the Protected Landscape Area Luzické hory Mountains (Northern Bohemia). *Vázky* 2001. Sborník referátu IV. celostátního semináře odonatologu, který se konal v Národním parku Sumava 2. - 5. 8. 2001. Seminár usporádali: ZO CSOP Vlasim, Správa NP Sumava, Správa. CHKO Blaník: 62-79. (in Czech with English summary). [The paper compiles and briefly discusses records of 35 species which were collected in 2000 and 2001.] Address: Waldhauser, M., Správa CHKO Luzické hory, Skolín 12, 47125 Jablonné v Podjestedi, Czech Republic

2855. Wootton, R.J. (2001): How insect wings evolved.. In: If. Woiwod, D.R. Reynolds & C.D. Thomas, [Eds], *Insect movement mechanisms and consequences*. CABI Publishing, Wallingford, ISBN 0-85199-456-3: 43-64. (in English). [There is now a majority support for the view that insect wings evolved from lateral segmental structures which were already mobile. The most plausible routes for the origin of flight appear to be either through parachuting and gliding, or through skimming on the surface of water. For the development of active flight, wing would initially need to enlarge, and to develop structural rigidity and a firm articulation to the thorax, then progressively to acquire structural adaptations for automatic, useful deformation when aerodynamically and inertially loaded. Thereafter the way would be open for specialization into different modes of flight, e.g. slow flight and hovering (Zygoptera: narrowing of the base, usually accompanied by vein fusion, etc.), or adaptations for flight over a wide speed range (Anisoptera: combining torsionally compliant wings with broad bases, usually associated with faster flight).] Address: Wootton, R.J., Hatherly Lab., Sch. 2857. Yanoviak, S.P., (2001): Container color and location affect macroinvertebrate community structure in artificial treeholes in Panama. *Florida Entomologist* 84(2): 265-271. (in English with Spanish summary). [I investigated the effects of habitat color and location on community structure in artificial water-filled treeholes in the forest of Barro Colorado Island, Panama. The macroinvertebrate fauna of 9 replications (5 in understory, 4 in tree-fall gaps) of black, blue, red, and green 650 ml plastic cups were censused weekly for 7 wks. Macroinvertebrate abundance and species richness were greater in understory cups than in gap cups. Seven species

colonized black cups exclusively. Black cups in the understory, and red and black cups in gaps, attracted more species on average than other colors. Species richness and abundance were consistently lowest in green cups. Species were more broadly distributed among cup colors in the understory, suggesting that diffuse light conditions influenced color perception. There was no overlap in species composition between water in the artificial treeholes and water held by red *Heliconia* bracts or green tank bromeliads." (Author) *Mecistogaster* ssp. was found one time in a black container in understory, and one time in a black container in gap. *Mecistogaster* on BCI avoid other phytotelmata, including bromeliads, and prefer treeholes. "It is reasonable to conclude that the presence ... only in black cups reflects a habitat color preference."] Address: Yanoviak, S.P., Evergreen State College, Lab 1, Olympia, WA 98505, USA

2862. Zimmer, K.D.; Hanson, M.A.; Butler, M.G.; Duffy, W.G. (2001): Size distribution of aquatic invertebrates in two prairie wetlands, with and without fish, with implications for community production. *Freshwater Biology* 46: 1373-1386. (in English). ["1. We compared the size distribution of aquatic invertebrates in two prairie wetlands, one supporting a population of fathead minnows and the other fishless. Both wetlands were sampled in three depth zones on three dates, allowing assessment of temporal and spatial variation. 2. We determined biomass of aquatic invertebrates in 17 log₂ size classes, and used these data to develop normalized size spectra. We also coupled size distributions with an allometric model to estimate relative production at the community level. 3. The composition of the invertebrate communities differed greatly between sites, and invertebrate biomass was higher in nearly all size classes in the fishless wetland. Intercepts of normalized size spectra were significantly different between wetlands, but slopes generally were not, indicating differences in

standing-stock biomass but similar size structures between the two invertebrate communities. Higher standing-stock biomass in the fishless wetland resulted in higher relative production per unit area, but similar size distributions resulted in similar mass-specific production (P/B) between wetlands. 4. Our results indicate that invertebrate communities in prairie wetlands may have relatively consistent size structures in spite of large differences in community composition and standing-stock biomass. We hypothesize that the observed differences are because of predation by the minnow population and/or differences in the macrophyte communities between the two sites. However, the relative importance of macrophytes and fish predation in structuring invertebrate communities in prairie wetlands is poorly known." (Authors) The biomass of Odonata depends from the stratum and the date of sampling. In the fishless pond Odonata biomass of e.g. the shallow stratum accounts to nearly 60% of the total macroinvertebrate biomass, and to nearly 50% on 23 June. Whereas in the pond supporting a population of the fathead minnow biomass in the mid-depth stratum accounts for less than 5% (app. 0% in the shallow and deep stratum); biomass was less than 5% on 19 May, no Odonata could be sampled on the two succeeding sampling dates.] Address: Zimmer, Kyle, D., Dept of Ecology, Evolution and Behavior, University of Minnesota, 100 Ecology, 1987 Upper Buford Circle, St Paul, MN 55108, USA. 2863. Zottoli, S.J.; Walfish, D.T.O.; Westbrooks, D.A.; Smith, D.C. (2001): Small tadpoles do not initiate a startle response before being struck by the labium of dragonfly larvae. *Society for Neuroscience* 27(2): 1984. (in English). ["Dragonfly larvae of the family Aeshnidae are voracious predators whose diet includes tadpoles. Larvae hydraulically protrude a labium that has movable hooks, which may attach to prey on contact. This rapid labial movement (13.8+-3.7ms to full extension; mean+-S.D.; n=10) may preclude the ability of tadpoles to use a startle response to escape being struck by the labium. Digital imaging (500 frames/s) was used to detect whether a tadpole startle response is involved in escape from the dragonfly labial strike. Dragonfly larvae (2.8+-1.7cm in total length; 6.5+-2.5mm head width; n=10) were held at 22degreeC and were not fed for three days prior to trials. In each trial a dragonfly larva was placed in the base of a 60X5mm petri dish, covered with conditioned water and allowed to acclimate for at least 10 min. A small tadpole (*Rana*, 12.3+-3.7mm in total length; n=10; purchased from suppliers) was then introduced into the dish and images of labial strikes were saved and analyzed. Tadpoles never displayed a startle response before being struck by the dragonfly labium. When tadpoles were hooked, they were almost always eaten or released by the dragonfly larvae and in a few cases the tadpole was able to break free from the labial hooks utilizing a startle response. When tadpoles were struck but not hooked, startle responses were initiated 23.8+-4.8ms (n=10) after contact by the labium. The results clearly indicate that small tadpoles do not initiate a startle response before being struck by the dragonfly labium. We hypothesize that the startle response may aid in escape from predation only after labial contact." (Authors)] Address: Zottoli, S.J., Biology, Williams College, Williamstown, MA, USA

- 2866.** Altwegg, R. (2002): Predator-induced life-history plasticity under time constraints in pool frogs. *Ecology* 83(9): 2542-2551. (in English). ["The mere presence of predators often decreases the growth rate of prey individuals, which devote energy and time to predator avoidance mechanisms. However, if time constraints are present, the prey individuals might be forced to neglect predators in order to grow faster. Amphibian larvae lower their activity when exposed to predators, which increases their survival probability but lowers their growth rate. I investigated how time constraints affect the growth strategies of pool frogs (*Rana lessonae*) in the presence and absence of caged (i.e., nonlethal) predators (*Anax imperator*), and what the consequences are for their survival during the larval and the subsequent terrestrial life stage. In two outdoor experiments, I limited the available development time by delaying the hatching date, and by simulating pond drying. Tadpoles whose hatching date was experimentally delayed reduced their development and their activity less in the presence of predators than did control tadpoles. The survival consequences of caged predators was similar for early- and late-hatched tadpoles. Tadpoles exposed to falling water level increased their developmental rate compared to constant-water-level controls. In response to predators, however, tadpoles decreased activity and developmental rate, regardless of the water level treatment. Survival in treatments combining fast drying and caged predators was lower than in the other treatments. These results suggest that time constraints critically affect the role of predators in the life history of pool frogs and might change the relative importance of lethal and nonlethal predator effects on their population dynamics." - 2867.** Altwegg, R. (2002): Trait-mediated indirect effects and complex life-cycles in two European frogs. *Evolutionary Ecology Research* 4(4): 519-536. (in English). ["Most animals actively avoid predators. If such a reaction reduces competitive ability, for example by reducing food intake, predator presence can lead to trait-mediated indirect effects. Because predator avoidance typically leads to reduced growth rather than reduced survival, its effect on population processes is difficult to assess. This is especially true for organisms with complex life-cycles, where predator avoidance during one stage is expected to lead to trait-mediated indirect effects if it has effects reaching into the following life stages. I experimentally investigated the effect of caged (thus non-lethal) dragonfly larvae on the competition between tadpoles of two frog species (*Rana lessonae* and *R. esculenta*) and on juvenile frog survival during the subsequent terrestrial stage. In response to caged predators, *R. lessonae* delayed metamorphosis more than *R. esculenta*, but they both metamorphosed heavier. These differences suggest the possibility of a competitive disadvantage for *R. lessonae* in the presence of predators, which could lead to trait-mediated indirect effects. However, the presence of predators did not modify competitive effects and had no measurable consequences on terrestrial survival. Regardless of the presence of predators, competition during the larval stage had large effects on metamorphosis and led to strongly decreased survival in the subsequent terrestrial stage. These results suggest that trait-mediated indirect effects are not important in this system, because the predator reaction of the tadpoles in both species had no measurable effect on the following life stage and, therefore, probably no strong effect on community dynamics." - 2868.** Andres, J.A.; Sanchez-Guillen, R.A.; Cordero Rivera, A. (2002): Evolution of female colour polymorphism in damselflies: testing the hypotheses. *Animal Behaviour* 63(4): 677-685. (in English). ["The existence of several female colour morphs is a conspicuous characteristic of many damselflies that show one male-like (androchrome) and several nonmale-like (gynochrome) morphs. We tested several adaptive hypotheses and the null model for the maintenance of female polychromatism (one androchrome and two gynochromes) in the damselfly *Ceriatagrion tenellum*. We tested the null model by comparing the degree of genetic differentiation between the colour locus and a set of 19 neutral RAPD loci in five populations. Our results indicate that selection is acting to maintain similar frequencies between populations at the colour locus. Using mark-recapture techniques we found that mating success is not dependent on female coloration. We tested the mimicry hypothesis by presenting live and dead models to males. Dead models were highly attractive irrespective of coloration. In contrast, with live models males could not distinguish between androchromes and other males, and were more attracted to gynochrome females. Despite this, within populations morph frequencies remained constant over time and mating was at random with respect to female coloration. However, there was a positive relationship between male density and androchrome frequency in a comparative study of eight populations. We discuss our results in the framework of sexual conflict theory and suggest that andro- and gynochrome females are using different strategies to control their number of matings. The different morphs might be maintained in a balanced polymorphism by a combination of density- and frequency-dependent mechanisms." 2871. Armstrong, A.J. (2002): Insects and the determination of priority areas for biodiversity conservation in KwaZulu-Natal province, South Africa. *African Entomology* 10(1): 11-27. (in English). ["The KwaZulu-Natal Nature Conservation Service is undertaking a long-term project to determine the value of untransformed land for biodiversity conservation, to map these areas in accordance with their relative values, and to identify and prioritize irreplaceable areas. The overall goal of the initial stage of the project was to use existing data and expertise to define areas of conservation importance in KwaZulu-Natal. The aim of this paper is to illustrate the procedures used to incorporate insect species and subspecies into the project, including those for identifying insects of conservation concern and for making a first assessment of their distribution and conservation status. A biodiversity hierarchy (from landscapes through ecosystems and communities to species and populations) forms the basis of the analysis. Information received from taxonomists working in South Africa in response to a questionnaire survey was used to choose the species for inclusion in the initial analysis. A total of thirty-seven species and subspecies endemic to the Province in certain families of Coleoptera, Diptera, Lepidoptera, Mecoptera and Odonata were included. Existing distribution data were collated and the potential distributions of the endemics were modelled at a scale of 4 ha. Factors that potentially influence the distributions of the endemics were gleaned from the literature. Database queries using distribution data with a spatial resolution of less than or equal to 250 m and cartographic overlays formed the basis of the modelling procedure. Two areas with little or no statutory protection, the high-lying grasslands of the northwestern region and much of the central region of the Province, are predicted to have a relatively high diversity of endemic insects. Fifty-one percent of the insect species and subspecies in the analysis met the two conservation goals, i.e. 1) at least 10% of their present distributions under formal conservation management, and 2) three such protected areas with viable populations. A benefit of modelling the potential distributions of endemics is that searching for populations of these insects can be directed to areas where they are expected to occur. The data collected can then be used to improve the distribution models for these insects, some of which are poorly known. The distributions and their associated conservation targets form a vital component of the iterative systematic conservation planning project currently underway in the Province." 2872. Balázs Bernáth, B.; Szedenics, G.; Wildermuth, H.; Horváth, G. (2002): How can dragonflies discern bright and dark waters from a distance? The degree of

polarisation of reflected light as a possible cue for dragonfly habitat selection. *Freshwater Biology* 47(9): 1707-1719. (in English). ["1. Based on the findings that some dragonflies prefer either 'dark' or 'bright' water (as perceived by the human eye viewing downwards perpendicularly to the water surface), while others choose both types of water bodies in which to lay their eggs, the question arises: How can dragonflies distinguish a bright from a dark pond from far away, before they get sufficiently close to see it is bright or dark? 2. Our hypothesis is that certain dragonfly species may select their preferred breeding sites from a distance on the basis of the polarisation of reflected light. Is it that waters viewed from a distance can be classified on the basis of the polarisation of reflected light? 3. Therefore we measured, at an angle of view of 20° from the horizontal, the reflection-polarisation characteristics of several ponds differing in brightness and in their dragonfly fauna. 4. We show that from a distance, at which the angle of view is 20° from the horizontal, dark water bodies cannot be distinguished from bright ones on the basis of the intensity or the angle of polarisation of reflected light. At a similar angle of view, however, dark waters reflect light with a significantly higher degree of linear polarisation than bright waters in any range of the spectrum and in any direction of view with respect to the sun. 5. Thus, the degree of polarisation of reflected light may be a visual cue for the polarisation-sensitive dragonflies to distinguish dark and bright water bodies from far away. Future experimental studies should prove if dragonflies do indeed use this cue for habitat selection." (Authors) Field studies were carried out near Zürich, Switzerland. The species surveyed are: *Enallagma cyathigerum*, *Anax imperator*, *Libellula depressa*, *Orthetrum cancellatum*, *Orthetrum brunneum*, *Pyrrhosoma nymphula*, *Coenagrion puella*, *Aeshna cyanea*, *Libellula quadrimaculata*, *Sympetrum striolatum*, *Lestes virens*, *L. sponsa*, *Chalcolestes viridis*, *Coenagrion pulchellum*, *Aeshna juncea*, *Cordulia aenea*, *Somatochlora flavomaculata*, *Leucorrhinia pectoralis*, and *Sympetrum sanguineum*.] Address: Horváth, G., Dept Biol. 2874. Beck, M.L.; Pruett-Jones, S. (2002): Fluctuating asymmetry, sexual selection, and survivorship in male Dark-Winged Damselflies. *Ethology* 108(9): 779-791. (in English). ["We examined fluctuating asymmetry and

morphology as they relate to reproductive success, territoriality, and relative survivorship in the dark-winged damselfly *Calopteryx maculata*. Fluctuating asymmetry was not correlated with any aspect of morphology in males, but it did predict mating status in males. Mating males showed significantly lower levels of forewing asymmetry than did non-mating males holding adjacent territories. While fluctuating asymmetry did not relate to survivorship or resource holding ability, body size did. Larger males were able to hold territories longer and lived longer than smaller individuals. We suggest that size is of greater importance in this species with regards to fitness and that fluctuating asymmetry may play a minor role by impacting short-term mating success." 2876. Beckemeyer, R. (2002): Some great plains Odonata records for 2000 and 2001. *Argia* 13(4): 7-8. (in English). [New records from Kansas, Oklahoma, and Nebraska, USA.] Address: Beckemeyer, R.J., 957 Perry Ave., Wichita, KS 67203-3141, USA. E-mail: royb@southwind.net

2877. Beckemeyer, R.J. (2002): Odonata in the Great Plains States: Patterns of distribution and diversity. *Bull. American Odonatology* 6(3): 49-99. (in English). ["Through the March, 1999 cutoff date of this study, a total of 320 species of dragonflies and damselflies, 73% of the Nearctic fauna, had been recorded as occurring in the 13 states comprising the Great Plains of the United States. These species are listed together with the Great Plains states in which they occur and the larger biogeographic region to which they belong. A significant latitudinal gradient in species richness was found to be present in the central Great Plains, with 194 species in Texas and 55 in North Dakota. A suite of similarity and diversity measure were mapped to visually display patterns of relationships of the state faunas. This process led to the identity of four faunal groups in the central Great Plains: Texas; Kansas - Oklahoma; Nebraska - South Dakota - Colorado - Iowa; and North Dakota. In terms of Nearctic biogeographical affinities, 43% of the Great Plains odonate fauna is of eastern origin. The large number of tropical species (42) in Texas contributes 14% of the Great Plains total. Northern transcontinental, western, southwestern, transcontinental, and central groups contribute 11%, 9%, 8%, 8%, and 7%, respectively. The Great Plains is home to major faunal boundaries and regions of overlap, many occurring in the central tier of states from Oklahoma north through North Dakota. The Hicks' 1957 assertion that the 32 to 36 inch precipitation isolines correlated with the area of overlap of eastern and western species groups in Oklahoma appears to hold true for Kansas as well." (Author) The paper contains a brief historic account on dragonfly research in the Great Plains states Colorado, Iowa, Kansas, Missouri, Minnesota, Montana, North Dakota, Nebraska, New Mexico, Oklahoma, South Dakota, Texas, and Wyoming. Distribution patterns of the following species are briefly discussed: *Enallagma anna* Williamson, *E. clausum*, *E. praevarum*, *Ischnura barberi*, *I. da-*

Beketow, M.A. (2002): Ammonia toxicity to larvae of *Erythromma najas* (Hansemann), *Lestes sponsa* (Hansemann) and *Sympetrum flaveolum* (Linnaeus) (Zygoptera: Coenagrionidae, Lestidae; Anisoptera: Libellulidae). *Odonatologica* 31(3): 297-304. (in English). ["Three different types of toxicological test were conducted, viz. the standard toxicological test at varying pH, a test with starved larvae and a test with different ionic composition of the water. For the larvae of *L. sponsa*, ammonia toxicity was examined only in the standard test at one pH value and in the test with varying ionic composition of the medium. Total ammonia was more toxic at elevated than at low pH to both *S. flaveolum* and *E. najas* larvae. In contrast, toxicity based on the un-ionized form appeared to increase with decrease in pH value. In general, larvae of all species have a high ammonia tolerance when compared to other aquatic animals. Tests with starved larvae showed that the ammonia tolerance of starved larvae of *S. flaveolum* was 3.7 times greater than that for the fed ones; for *E. najas*, this difference was only 1.2 times, explanations of this effect are discussed. Tests in varying ionic composition of the water illustrated that the absence of sodium ions accounts for a considerable increase in ammonia toxicity. It is interesting that a similar trend was found for fishes and crustaceans. Mechanistic explanations, which may differ from that for other groups, are proposed. Odonate larvae seem to be unsuitable for the bioindication of ammonia pollution." (Author)] Address: Beketow, M.A., Department of Zoology, Novosibirsk State Pedagogical University, P. O. 2887. Boudot, J.-P.; Jacquemin, G. (2002): Inventaire et statut des libellules de Lorraine. *Société Lorraine d'entomologie*: 68 pp. (in French). [This atlas of the Lorrainean Odonata (NE-region of France) provides detailed maps and information on 66 species known from the region. Information on maps are differed for the periods 1863-1969 and 1970-2001. Some additional species occurring close to the borders of the region or expected to be found soon are treated too. This is a highly informative atlas with a lot of original material.] Address: Société Lorraine d'Entomologie, c/o Laurent Godé, 2ter, Quai Choiseul, F-54000 Nancy, France. E-mail: laurent.gode@pnr-lorraine.com

2888. Brackenbury, J. (2002): Kinematics and hydrodynamics of an invertebrate undulatory swimmer: The damselfly larva. *Journal of Experimental Biology* 205(5): 627-639. (in English). ["The kinematics and hydrodynamics of free-swimming larvae of *Enallagma cyathigerum* were investigated using videography combined with a simple wake visualisation technique (tracer dyes). Damselfly larvae are undulatory swimmers with two distinct styles of movement: 'slow' swimming, in which body undulation is assisted by paddling of the legs, and 'fast' swimming, in which the legs are inactive. In both cases, the wake consists of discrete ring vortices shed from the caudal fin at the end of each half-stroke. The vortices propagate away from the mid-line, alternately to one side of the body then the other, at an angle of 67degree from dead aft. There is no aft-flowing jet such as that observed in the wakes of continuously swimming fish that use caudal fin propulsion. The estimated momentum within the vortices, and the resultant thrust on the body are in tolerable agreement with calculations based on the large-amplitude bulk momentum model of fish locomotion. However, the drag on the body is not known, so it cannot be concluded with certainty that a force balance exists. The agreement between experiment and prediction gives confidence to the idea that most, if not all, of the vorticity generated by the swimming larva is located within the observable wake elements." 2889. Braddy, S.J.; Briggs, D.E.G. (2002): New Lower Permian Nonmarine Arthropod Trace Fossils From New Mexico And South Africa. *Journal of Paleontology* 76(3): 546-557. (in English). ["The Lower Permian (Late Wolfcampian) marginal marine facies of the Robledo Mountains Member (Hueco Formation) of the Robledo Mountains, New Mexico, contains a diverse ichnofauna dominated by vertebrate trackways. Four new arthropod ichnotaxa are described. *Tonganoxichnus robledoensis* new ichnospecies, consists of repeated small traces comprising imprints of anteriorly directed legs, an elongate tapering abdomen, and a thin tail. *Hedriumiichnus apacheensis* new ichnogenus and ichnospecies consists of isolated small traces comprising imprints of

laterally-directed legs, a broad tapering abdomen, and a short tail. *Rotterodichnium major* new ichnospecies is a large trace with imprints of the head and thorax, a long thin abdomen and three pairs of legs, increasing in length posteriorly. *Quadrispinichna parvia* new ichnogenus and ichnospecies consists of four diverging or sub-parallel linear or curvilinear imprints of approximately equal length. *Tonganoxichnus*, previously known from the Upper Carboniferous of eastern Kansas, is interpreted as produced by a jumping monuran (an extinct group of wingless insects). *Hedriumichnus*, known only from the Robledo Mountains, is interpreted as the resting trace of a nymph of a primitive Ephemeroptera or Plecoptera. *Rotterodichnium*, previously known from the Lower Permian of Germany, is interpreted as the resting trace of a large dragonfly-like form (Protodonata, Odonata, or Megasecoptera). *Quadrispinichna*, previously recorded but not named, from the Lower Permian *Ecca* succession of South Africa, is interpreted as a resting trace of a crustacean. These rare traces increase our understanding of the diversity and behavior of nonmarine arthropod communities in the Lower Permian." (Author)] Address: Braddy, S., Department of Earth Sciences, University of Bristol, Queen's Road, Wills Memorial Building, Bristol, BS8 1RJ, UK. E-Mail: S.J.Braddy@bris.ac.uk

2890. Braune, E.; Söndgerath, D. (2002): Biodiversity of dragonflies in arid regions regarding habitat variability. *Verhandlungen der Gesellschaft für Ökologie, Cottbus 2002*: 290. (in English). [Verbatim: "We examined factors that regulate the biodiversity of dragonflies within the scope of a sub-project of BIOTA Africa. The main aim of this study is to construct models for the prediction of the dispersal of the dragonflies. The areas under investigation are the ephemeral river catchments in western Namibia. In these arid regions changes in the biodiversity of the Odonata can be expected through changes in the water budget on the local scale, as well as through largescale processes like the climate change. Both processes are influencing the habitat quality and quantity. To model the changes in the population dynamics the first step is to identify the factors which are responsible for the development of a population. Different multivariate analysis methods are used. For single species habitat suitability models are build up using logistic regression. Biotic and abiotic parameters which were recorded during a one year field period in a monitoring program throughout the western river catchments are used as input data. Additionally artificial parameters describing the structural diversity of the habitats were generated. On the (micro-) habitat scale we identified for the most common species habitat properties which favour the occurrence of the adult dragonflies (see Figure 1). These results are supported by field experiments carried out within our project. By incorporating the changes of the habitat quality, resulting in the growth or decline of local populations, the basis for the spatially explicit modelling of the population dynamics is established. In the next step models for the local population dynamics will be linked with each other through a density- and habitat quality dependent dispersal. Figure 1: Example for habitat suitability models for two namibian dragonfly species. L.h.s.: univariate model for *Crocothemis erythraea*, r.h.s.: bivariate model for *Orthetrum chrysostigma*."] Address: Braune, E., Institut für Geoökologie, Technische Universität Braunschweig, Langer Kamp 19c, D-38106 Braunschweig, Germany. 2891. Brodin, T.; Johansson, F. (2002): Effects of predator-induced thinning and activity changes on life history in a damselfly. *Oecologia* 132: 316-322. (in English). ["We investigated how the lethal and non-lethal presence and absence of a fish predator, perch (*Perca fluviatilis*), influenced behaviour, numbers emerging, size at emergence, and development rate of the damselfly *Lestes sponsa*. The experiment was carried out in outdoor artificial ponds and spanned from the egg stage to emergence of the damselflies. During the experiment food resources for the damselflies were continuously monitored. Damselflies exposed to a lethal predator showed a significantly lower activity level than those in the absence of predators or subjected to a non-lethal predator. Half-way through the larval stage the reduction in activity level was correlated with the presence of lethal predators, and at the end of the larval stage with higher zooplankton densities. Though larvae decreased activity level, size at emergence was larger and development time faster for individuals in the lethal predator treatment. Since fewer larvae emerged from that treatment we interpret the larger size at emergence to be an effect of a combination of thinning and higher zooplankton densities." (Authors)] Address: Brodin, T., Animal Ecology, Department of Ecology and Environmental Science, Umea University, 90187 Umea, Sweden. E-mail: tomas.brodin@eg.umu.se

2892. Brunke, M.; Hoffmann, A.; Pusch, M. (2002): Association between invertebrate assemblages and mesohabitats in a lowland river (Spree, Germany): A chance for predictions?. *Arch. Hydrobiol.* 154: 239-259. (in English). ["The influence of hydrological and sedimentological variables on invertebrate assemblages was investigated in the 6th order lowland river Spree (Brandenburg, Germany). The river bottom consisted of eight visually distinguishable organic and inorganic mesohabitats: Dreissena-bank, unionid mussel bed, rip-rap, coarse woody debris, alder roots, stable sand, shifting sand, and mud. The mesohabitats differed in their physical structure, substrate properties, temporal stability, flow velocity and grain size composition. Taxon richness and abundances varied markedly between mesohabitats. Ordination analyses revealed significant differences in taxonomic composition and dominance structure. Nevertheless, similarities in assemblage structure were found for (a) Dreissena-banks and unionid beds, (b) alder roots and coarse woody debris and (c) shifting sand, stable sand and mud. Thus four main habitat groups can be distinguished; mussel, rip-rap, woody, and fine sediment mesohabitats. Mussel mesohabitats, rip-rap and wood mesohabitats exhibited transitions in assemblage structure towards fine mesohabitats. In the case of mussel and wood mesohabitats, these transitions were temporal and occurred during extended periods of low flow and concomitant deposition of seston. In rip-rap these transitions were spatial and occurred when distances to fine sediment mesohabitats were small and nearbed flow velocities were low. Mesoscale predictions of assemblages for this section of river appear to be feasible when processes are taken into account that might affect transitions." (Authors) Only *Gomphus vulgatissimus* occurred exclusively in fine sediment mesohabitats, *Calopteryx* nearly exclusively in woody mesohabitats.] Address: Brunke, M., Institute of Freshwater Ecology and Inland Fisheries, Department of Lowland Rivers, Müggelseedamm 310,12587 Berlin, Germany. 2896. Burcher, C.L.; Smock, L.A. (2002): Habitat distribution, dietary composition and life history characteristics of odonate nymphs in a blackwater coastal plain

stream. *American Midland Naturalist* 148(1): 75-89. (in English). ["The ecology and life histories of odonates were studied in a headwater, sand-bottomed coastal plain stream in Virginia. Quantitative sampling of odonates in sand and silt sediments, on submerged snags and in debris dams was conducted monthly for 13 mo. Six species of odonates were common in the stream. *Calopteryx maculata* had a univoltine life history, whereas *Boyeria vinosa*, *Cordulegaster maculata*, *Gomphus cavillaris*, *Hagenius brevistylus*, and *Progomphus obscurus* were semivoltine. The odonates were most abundant in debris dams, less abundant in silt and sand sediments and least abundant on snags. Habitat-specific production of odonates was 1.3 g m⁻² y⁻¹ in debris dams and 0.1-0.3 g m⁻² y⁻¹ in the sand, silt and snag habitats. The production to biomass ratio (P/B) for *Calopteryx* was 5.9, whereas ratios for semivoltine species ranged from 2.0-4.0. Analysis of overlap in the use of habitat, food and time showed that greatest ecological separation of the species was in their different use of habitat. *B. vinosa* and *C. maculata* primarily inhabited debris dams, *H. brevistylus* and *G. cavillaris* were most abundant in silt and *P. obscurus* was found almost exclusively in sand. *Cordulegaster maculata* occurred throughout the stream except on snags. Narrow niche breadths for *B. vinosa*, *C. maculata* and *P. obscurus* based on their use of habitat suggest high fidelity of these species to one habitat, whereas *C. maculata*, with the broadest habitat niche breadth, was a habitat generalist. There was little difference among the species in prey items. Trophic niche breadths of all species were broad, all species feeding on a wide variety of invertebrates, in particular Chironomidae, Ephemeroptera and Plecoptera. Little ecological separation of the species occurred based on their use of time, all species occurring in the stream throughout the year with little staggering of life history events or growth patterns. Seasonal patterns of changing resource availability and the dynamic nature of the stream environment likely are important in regulating the distribution, abundance and interactions of the odonate community in this stream." (Authors)] Address: Smock, L.A., Department of Biology, Virginia Commonwealth University, Richmond, Virginia, U.S.A. 23284-2012.

2897. Buskirk, J. van (2002): A comparative test of the adaptive plasticity hypothesis: Relationships between habitat and phenotype in anuran larvae. *American Naturalist* 160(1): 87-102. (in English). ["The hypothesis that phenotypic plasticity is maintained by divergent natural selection acting across different environments predicts that populations and species exposed to highly variable environments will express high levels of plasticity. I tested this prediction by measuring the behavioral and morphological responses to aeshnid dragonfly larvae of 16 tadpole species and asking whether predator-induced plasticity is greater in species that experience more variable densities of predators in nature. Tadpole phenotypes were measured in a series of similar experiments in outdoor artificial ponds carried out over a 9-yr period. I quantified tadpole habitats by soliciting evaluations by seven to 36 experienced field observers for each species. There were large differences among species in phenotype, mostly in agreement with earlier descriptions. Nearly all species responded to dragonflies by decreasing activity and body length relative to overall body size and by increasing relative tail fin depth, although the magnitude of the responses differed among species. There was a significant positive

phylogenetic correlation between morphological plasticity and variability in exposure to predators, thus upholding the adaptive hypothesis. The correlation between behavioral responses and habitat variability was not significant, and there was little relationship between behavioral and morphological plasticity, raising the possibility that behavioral responses evolve under different scales of environmental variation than morphological responses." (Author)] Address: Buskirk, J. van, Institute of Zoology, University of Zürich, CH-8057 Zürich, Switzerland. E-mail: jvb@zool.unizh.ch

2898. Buskirk, J. van; Müller, C.; Portmann, A.; Surbeck, M. (2002): A test of the risk allocation hypothesis: Tadpole responses to temporal change in predation risk. *Behavioral Ecology* 13(4): 526-530. (in English). ["The risk allocation hypothesis predicts that temporal variation in predation risk can influence how animals allocate feeding behavior among situations that differ in danger. We tested the risk allocation model with tadpoles of the frog *Rana lessonae*, which satisfy the main assumptions of this model because they must feed to reach metamorphosis within a single season, their behavioral defense against predators is costly, and they can respond to changes in risk integrated over time. Our experiment switched tadpoles between artificial ponds with different numbers of caged dragonfly larvae and held them at high and low risk for different portions of their lives. Tadpoles responded strongly to predators, but they did not obey the risk allocation hypothesis: as the high-risk environment became more dangerous, there was no tendency for tadpoles to allocate more feeding to the low-risk environment, and as tadpoles spent more time at risk, they did not increase feeding in both environments. Our results suggest that the model might be more applicable when the time spent under high predation risk is large relative to the time required to collect resources." (Authors)] Address: Buskirk, J. van, Institute of Zoology, University of Zürich, CH-8057 Zürich, Switzerland. E-mail: jvb@zool.unizh.ch

2899. Buskirk, J. van; Arioli, M. (2002): Dos age response of an induced defense: How sensitive are tadpoles to predation risk?. *Ecology* 83(6): 1580-1585. (in English). ["Models of behavior and life history evolution under predation risk often assume that animals can detect and respond to subtle temporal, and spatial variation in mortality risk, but there is little evidence supporting this assumption. We measured phenotypic responses of *Rana lessonae* tadpoles to variation in apparent predation risk signaled by different numbers of *Aeshna cyanea* dragonfly larvae consuming different quantities of tadpoles. The experiment took place in 80-L artificial ponds, and the predators were confined within cages so that they could not capture the experimental animals. There was good support for continuous dosage response curves for most behavioral and morphological traits, which indicates sensitivity to graded risk and therefore supports the assumptions of many models. Behavioral traits were most responsive to the number of tadpoles killed by the predators, whereas morphological traits responded to the number of dragonflies independent of the predators' diet. The results imply that behavioral and morphological responses can be triggered by different cues, and suggest that increasing investment in defensive traits entails increasing fitness costs." 2900. Butler, S.G. (2002): The larva of *Macromia euterpe* Laidlaw, 1915 (Anisoptera: Macromiidae). *Odonatologica* 31(4): 383-388. (in English). [An exuvia of *M. euterpe* is described, illustrated and compared with *M. moorei fumata* Krüger and *M. westwoodi* Selys. In addition, larval head and protothorax of *Macromia amphigena* Selys, 1871 (Japan), *Macromia flavocolorata* Fraser, 1922 (Nepal), and *Phyllomacromia trifasciata* (Rambur, 1842) (Madagascar) are illustrated.] Address: Butler S.G., Red Willow, All Stretton, Shropshire SY6 GHN, United Kingdom

2901. Cannings, R.A. (2002): Introducing the dragonflies of British Columbia and the Yukon. Royal British Columbia Museum, Victoria, B.C. ISBN 0-7726-4637-6 (paper): 96 pp.. (in English). [This book introduces into the odonate fauna of two Canadian provinces. It is lavishly illustrated. With one exception (*Somatochlora septentrionalis*), all 88 species are documented with color photographs. Rob Cannings has wisely included line drawings of structural details for some of the more difficult genera. After introducing into Odonata, and the regional odonate habitats, the species are briefly described and compared it with closely related ones. Additional information refer to range, and "field notes" include habitat and flight period. This is a really sophisticated book, and its low price makes it very attractive. If I should visit B.C. for odonatological reasons, I would not miss any information! (Martin Schorr)] Address: The book (CAN Dollar 9.95.) can be ordered from: Royal Museum Shop, Royal British Columbia Museum, 675 Belleville Street, Victoria, B.C., V8W 9W2, Canada

2902. Carle, F.L.; Kjer, K.M. (2002): Phylogeny of *Libellula* Linnaeus (Odonata: Insecta). *Zootaxa* 87: 1-18. (in English). ["Phylogenetic analysis was performed on a set of 242 morphological characters. The taxon sample included 31 *Libellula*, and representative species from selected libelluline tribes, from all libellulid subfamilies, from all libelluloid families, from all anisopteran superfamilies, and *Epiophlebia*. *Corduliinae* was shown to be paraphyletic even among genera characterized by a well developed anal loop bisector. *Sympetrini* was found to be polyphyletic with *Crocothemis* the sister group to *Libellulini*. The traditional placement of *Trameini*, far from *Libellulini* is in doubt, because it is here placed as the sister group to *Crocothemis* + *Libellulini*. Kennedy's phylogeny of *Libellula* was largely corroborated, with the following exceptions: the subgenera *Libellula*, *Eolibellula*, and *Syntetrum* form a monophyletic group which is the sister group to a clade including *Bellonia*, *Holotania*, *Neotetrum*, and *Eotainia* subgenus nov. [type species *Mesothemis composita* Hagen]; and *Eurothemis* is determined to be the sister group of *Ladona* instead of *Neotetrum*. In addition we confirm *Bellonia* to be monophyletic, and find *Platetrum* + *Platthemis* to form a monophyletic group, sister to *Ladona* + *Eurothemis*; these four subgenera together form the sister group to *Libellula sensu stricto* (s.s.)." (Authors)] Address: Carle, F.L.; Kjer, K.M., Dept of Entomology, Cook College Rutgers, The State University of New Jersey, 93 Lipr Brunswick, NJ 08901, USA. E-mail: carle@aesop.rutgers.edu

nia, USA] Address: Carpenter, N. M., U.S. Fish and Wildlife Service, 752 County Road 99W, Willows, CA, 95966, USA. E-Mail: mikecarpenter@r1fws.gov

2904. Catling, P.M.; Brownell, V.R. (2002): Large numbers of *Aeshna interrupta* in southeastern Saskatchewan. *Argia* 13(4): 7. (in English). [In July 2001, thousands of *A. interrupta lineata* were seen flying over the (agricultural) prairie landscape while driving along the trans-Canada highway from Ottawa in eastern Ontario to coastal British Columbia. This species "must have a very significant influence on the prairie ecosystem as both predator and prey." From the view of impacts of roads on ecosystems resp. Odonata, some interesting details of road kills by vehicles are outlined.] Address: Catling, P.M., 2326 Scrivens Drive, R.R. 3, Metcalfe, Ontario K0A 2P0, Canada. E-mail: brownell@achilles.net

2905. Cauchie, H. (2002): Chitin production by arthropods in the hydrosphere. *Hydrobiologia* 470(1-3) : 63-95. (in English). ["Chitin is widely distributed in nature and its annual production is thought to be huge. However, the chitin production has been rarely estimated in aquatic ecosystems, despite the growing economic interest in this polymer. Arthropods are one of the main chitin producers in the hydrosphere and a correct evaluation of the chitin production by these organisms in the different marine and freshwater ecosystems is of prime interest to understand their importance in the biogeochemical cycles of carbon and nitrogen. Such evaluation is also worth considering to achieve a rational exploitation of crustaceans which are currently the major source of chitin for the industry. Annual chitin production of crustaceans and insects in aquatic ecosystems was estimated on the basis of annual tissue production estimates and body chitin content measurements. About 800 annual tissue production estimates were collected from the literature. Estimates mainly concerned continental fresh waters and neritic ecosystems. Data were almost inexistent for athalassohaline and oceanic ecosystems. On the whole, 60% of the production estimates fell between 0.1 and 10.0 g dry weight m² super(-2) yr super(-1). Published chitin levels in crustaceans and insects ranged from 3 to 16% of the whole body dry weight. Data were, however, lacking for some major groups such as trichopterans or amphipods. Aquatic insects and crustaceans were therefore collected and assayed for chitin using a highly specific enzymatic method. The chitin content of the collected insects (Coleoptera, Diptera, Ephemeroptera, Odonata, Plecoptera, Trichoptera) varied from 3 to 10% of the whole body dry weight; that of the collected crustaceans (Amphipoda, Branchiopoda, Copepoda) from 2.5 to 8.5% of the whole body dry weight. Total annual chitin production by arthropods had been estimated to 28 x 10⁶ T chitin yr super(-1) for the freshwater ecosystems, to 6 x 10⁶ T chitin yr super(-1) for athalassohaline ecosystems and to 1328 x 10⁶ T chitin yr super(-1) for marine ecosystems. The importance of the chitin production corresponding to the formation of exuviae and peritrophic membranes in arthropods and the chitin production by non-arthropod organisms in the chitin budget of aquatic ecosystems was highlighted and discussed." 2906. Cham, S. (2002): Mate guarding behaviour during intense competition for females in the Common Blue Damselfly *Enallagma cyathigerum* (Charpentier). *J. Br. Dragonfly Society* 18(1/2): 46-48. (in English). ["These observations demonstrate that single males of *E. cyathigerum* will harass tandem pairs as they approach the oviposition site and also when oviposition commences. When densities are high it is in the interest of the males to stay in tandem with the female for as long as possible. This increases his chances of guarding the female until she has laid the eggs that he is likely to have fertilized. This guarding behaviour is imperative at high densities as aggressor males appear to go to great lengths to 'win over' a female and are prepared to submerge in order to achieve tandem." 2909. Conrad, K.F.; Willson, K.H.; Whitfield, K.; Harvey, I.F.; Thomas, C.J.; Sherratt, T.N. (2002): Characteristics of dispersing *Ischnura elegans* and *Coenagrion puella* (Odonata): Age, sex, size, morph and ectoparasitism. *Ecography* 25(4): 439-445. (in English). ["In this study we assessed whether individuals of the damselfly species *Ischnura elegans* and *Coenagrion puella* that moved between ponds differed in their mean characteristics from individuals that did not move. Overall, the sex (female) and species (*C. puella*) that spent the most time away from the breeding site was more likely to move between ponds. *Ischnura elegans* males that dispersed had significantly longer forewings than males that did not, while male *C. puella* parasitised by water mites were more likely to disperse than unparasitised males. There was no evidence for differences in dispersal rates among the female colour forms of either *I. elegans* or *C. puella*. In general, the differences in dispersal characteristics between sexes and species could be explained by underlying variation in activity and mobility. The majority of dispersal between breeding sites by *C. puella* and *I. elegans* did not appear to be directed, but probably arose from chance movements occasionally taking individuals to a different pond from which they emerged." - 2910.** Corbet, P.S.; Chowdhury, H. (2002): Voltinism of the Common Blue Damselfly *Enallagma cyathigerum* (Charpentier) in a Scottish loch: a preliminary study. *J. Br. Dragonfly Society* 18(1/2): 23-39. (in English). ["During 1986-1987 a larval population of *E. cyathigerum* was sampled repeatedly from a *Littorella* sward near the margin of a small Scottish loch (Rohallion Loch) to determine the species' voltinism and to characterize ontogenetic changes in external morphology. Size-overlap between hatching cohorts made it difficult to trace cohort development but results support the inference that most larvae were developing as semivoltine summer species, spending their second (last) winter in stadia F-I (mainly) and F-0, while a few larvae showed the potential to complete development in either one or three years. Extrapolation backwards from the last three stadia revealed that larvae completing development passed through about 15 stadia (including the prolarva). Regular, heavy stocking of Rohallion Loch with insectivorous fish (including trout) invited comparison with observations by Macan in a tarn in the Lake District with attributes, including aquatic macrophytes and a predominantly semivoltine population of *E. cyathigerum* occupying *Littorella*, resembling those of Rohallion Loch. In Rohallion Loch, larvae of *E. cyathigerum*, though known from research in North America to be vulnerable to predation by fish, were maintaining dense populations in the presence of fish, probably by obtaining refuge in *Littorella* swards. We emphasize the need to discover secure morphological characters for distinguishing small larvae of *E. cyathigerum* from those of other coenagrionids." - 2911.** Cordoba-Aguilar, A. (2002): Wing pigmentation in territorial male damselflies, *Calopteryx haemorrhoidalis*: a possible relation to sexual selection. *Animal Behaviour* 63(4): 759-766. (in English). ["One striking characteristic in adult males of some odonate species is the presence of wing pigmentation. In *Calopteryx* species, males show a series of pre- and postcopulatory behavioural displays during which they face females while showing their pigmented wings. One hypothesis to explain the precopulatory flying displays and the associated wing pigmentation is that they may serve a sexual selection function. I investigated this in the territorial damselfly *Calopteryx haemorrhoidalis*. Males of this species defend aquatic substrates that females use for oviposition. Observational evidence indicated that males with a higher proportion of wing pigmentation were more likely to defend a territory, obtained more matings, had fewer gut parasites, survived in the study site and stayed in territories for longer. Experimental evidence suggested that the relationship mating success and wing pigmentation still held when controlling for the size of the substrate defended by territorial males. Similar to other studies in the *Calopterygidae*, these results suggest that wing pigmentation may be favoured by sexual selection. I discuss, however, whether an alternative function for male copulatory courtship displays and wing pigmentation, as sexual and/or species recognition, may also explain the evolution of these traits." - 2914.** Crowley, P.H.; Johnsson, F. (2002): Sexual dimorphism in Odonata: age, size, and sex ratio at emergence. *Oikos* 96(2): 364-378. (in English). ["Males and females of many organisms differ in important life-history and behavioral characters. Following its recent optimization analysis of sexually dimorphic life histories, we employed an odonate-like parameter set to identify patterns of life history and behavior to be expected in an odonate population. The default parameter magnitudes generated a smaller body size and shorter development time for males than for females, which resulted in a male-biased sex ratio. Whether population growth as density dependent or density independent, and whether development time was fixed or flexible had major impacts on life-history features. The model generated five general production, for odonate systems. (1) For species with fixed development times, males and females should differ more in activity level, growth and mortality rates than for species, with flexible life cycles. (2) In species with fixed development times population at high latitude or high altitude should be more active, emerge and reproduce at smaller size and have a more male-biased sex ratio than low latitude and low altitude populations. (3) In density-dependent populations, with density dependence mediated by activity-dependent mortality higher predation rates should increase activity levels and reduce development time in species with flexible development times. (4) For species with flexible development times, in strongly density-dependent population, with density dependence mediated by mortality, activity levels should decrease and development times should increase at high prep.abundance. (5) Males should be larger at emergence relative to female, and the sex ratio at emergence should be more female-biased in territorial than in non-territorial species. Existing empirical evidence concerning these predictions is generally sparse and equivocal focused tests are clearly needed." (Authors)] Address: Crowley, P.H., Umea Univ, Dept Ecol & Environm Sci Anim Ecol, SE-90187 Umea, Sweden

2923. Dijkstra, K.-D.; Kalkman, V.; Ketelaar, R.; Weide, M. van der (2002): *De Nederlandse Libellen* (Odonata). *Nederlandse Fauna* 4. ISBN 90-5011-154-8: 440 pp. (in Dutch with English summaries). [Under the auspices of the Nationaal Natuurhistorisch Museum Naturalis, Leiden, the Koninklijke Nederlandse Natuurhistorische Vereniging, Utrecht, and the European Invertebrate Survey, Leiden, and in cooperation with numerous amateur odonatologists, the authors here present an extraordinarily fascinating book on the Netherlands Odonata. It is a heavy weighting book in every sense. Information is presented in 15 chapters, an appendix lists the names of the contributors, and contains the index and a regional gazetteer. Chap. 1 introduces into Dutch dragonfly research and outlines the management to compile the tremendous database which is the fundament of the dot maps. Chap. 2 discusses

aspects of morphology in relation to the life history of Odonata. Excellent illustrations help to understand the Dutch written texts (here and in the following chapters!). Chap. 3 is dedicated to phenological aspects, which means that the different stades (egg, larvae, imago) are discussed with emphasize on the timing of the life cycle of dragonflies. Chap. 4 outlines life history aspects and behaviour of the Odonata in relation to their environment (landscape, weather, prey, enemies). I want to stress the (informative) quality of some most intrusive colour photos of "beasts" preying on Odonata. Chap. 5 is an introduction into evolution and phylogeny of Odonata, it also presents a map of regional diversity on a global scale. The focus is set on the (global) distribution of the European Odonata families. This chapter also provides the folk names of the Odonata in the Netherlands, and explains the (Latin / Greek) nomenclature. Chap. 6 gives a detailed and well illustrated introduction in the identification of Odonata, and provides the identification keys for the adults. Some of the illustrations belong definitely to the best I have seen for European Odonata. Chap. 7 describes in detail the habitats of the species, and maps the potential distribution of special habitats in the Netherlands, which likewise limits the potential distribution of specialised species. Changes (population development trends) in the dragonfly fauna are dealt with in Chap. 8. Natural and anthropological factors which cause the species turn over are discussed. Aspects of conservation and management of species and habitats are treated in Chap. 9. It details on the Red list and results of the monitoring scheme as well as on conservation measures. Chap. 10 outlines details of data collection and validation of the data collected in the framework of the mapping scheme. The core of the book is Chap. 11; each of the 70 species observed in The Netherlands is treated monographically: A more general introduction is followed by a detailed description of the habitat, the life history (egg, larvae, imago, phenology, dispersal potential, cooccurring species), areal, distribution in the Netherlands, conservation measures, and an English summary. Graphs (mostly maps) demonstrate the distribution in different periods and in western Europe, the flight period and a tab. with the cooccurring species (dominances). The quality of the colour photos is impressive, and definitely one of the most amazing high lights of the book are some water colour paintings showing in some cases the species damaged or in more than unfavourable situations. In most cases, these pictures demonstrate simply the beauty of our favorite insects. Compliments to the illustrators! Chap. 12 is devoted to the study of dragonflies. Chap. 13 contains a glossar, and Chap. 14 an extensive bibliography. Chap. 15 summarizes the previous chapters briefly in English. The books price is Euro 74,50 + handling (app. 16,- Euro). This looks much, but not too much for this book! The past two years have produced some remarkable books on dragonflies, may be that the book on the Netherlands dragonflies is the most impressive of all of them. This book may not be missing in any odonatological library. (Martin Schorr)] Address: Publisher: KNNV Publishing House, PO Box 19320, NL-3501 DH Utrecht, The Netherlands. www.knnvuitgeverij.nl

2933. Ellenrieder, N. von (2002): A phylogenetic analysis of the extant Aeshnidae (Odonata: Anisoptera). Systematic Entomology 27: 437-467. (in English). ["A cladistic analysis of the world Aeshnidae is presented, based on fifty-eight characters of adult and larval anatomy. The ingroup taxa include all the extant genera of Aeshnidae, and the austropetaliid genera Phyllopetalia and Hypopetalia were chosen as the outgroup. The strict consensus tree obtained after successive weighting shows that the subgroups defined traditionally for Aeshnidae are paraphyletic or polyphyletic. The previous reclassification derived from analyses based on wing venation is supported in terms of the monophyly of Aeshnidae, Gomphaeschninae and its sister group comprising the remaining Aeshnidae. Gomphaeschninae is confirmed as sister group of the remaining Aeshnidae (= Aeshnodea Bechly). The sister-group relationships between Gomphaeschninae+Sarasaeschna and Linaeschna+Oligoaeschna are corroborated. Within Aeshnodea, three monophyletic groups emerged: Boyeria + (Petaliaeschna+ (Limnetron+Gynacanthaeschna+Periaeschna)) + ((Cephalaeschna+Caliaeschna)+(Allopetalia (Notoaeschna+Spinaeschna))); Dendroaeschna+(Ephiaeschna+ (Aeschnophlebia+ (Nasiaeschna+ (Tetracanthagyna+Brachytron))); and Polycanthagyna+ (Basiaeschna+ (Amphiaeschna+ (Indaeschna+ (Oplonaeschna+ (Racenaeschna+Plattycantha+Agyrtacantha+Triacanthagyna+ (Subaeschna+ Austrogynacantha+Gynacantha) + (Heliaeschna+ (Neuraeschna+Staurophlebia))) + ((Castoraeschna+ Coryphaeschna+Remartinia) + (Oreaeschna+ (Aeshna+ (Anaciaeschna+ ('A.'isosceles+Andaeshna) + (Anax+Hemianax)))))). Additional informative characters are required to test the relationships suggested here between the main groups of Aeshnodea and some enigmatic basal taxa (Antipodophlebia, Austroaeschna, Acanthaeschna, Telephlebia, Austrophlebia and Planaeschna)." (Author) SEM photos or drawings of the following species are provided: Brachytron pratense (Müller, 1764), Rheopetalia apicalis (Selys 1858), Oligoaeschna pryleri (Martin 1909), Boyeria vinosa (Say 1839), Oplonaeschna armata (Hagen 1861), Remartinia luteipennis (Burmeister 1839), Anax amazili (Burmeister 1839), Hemianax papuensis (Burmeister 1839), Allopetalia reticulosa Selys 1873, Nasiaeschna pentacantha (Rambur 1842), Caliaeschna microstigma (Schneider, 1845), Spinaeschna tripunctata (Martin 1901), Limnetron debile (Karsch 1891), WStaurophlebia reticulata (Burmeister 1839), Coryphaeschna perrensi (McLachlan 1887), Gynacantha bifida Rambur 1842, Aeshna absoluta Calvert 1952, Acanthaeschna victoria Martin, 1901, Austropetalia patricia (Tillyard 1910), Andaeschna rufipes (Ris 1918), Ephiaeschna heros (Fabricius 1798), Gomphaeschna furcillata (Say 1839), Basiaeschna janata (Say 1839), Aeshna cornigera Brauer 1865, Hypopetalia pestilens MacLachlan 1870, Coryphaeschna adnexa (Hagen 1861), Anaciaeschna jaspidea (Burmeister 1839), Anaciaeschna isoceles (Müller, 1767), Andaeschna andresi (Racenis 1958), and Aeschnophlebia anisoptera Selys 1883.] Address: Ellenrieder, Natalie von, Instituto de Limnología "Dr. Raúl A. 2935. Evans, H.E. (2002): A Review of Prey Choice in Bembicine Sand Wasps (Hymenoptera: Sphecidae). Neotropical Entomology 31(1): 1-11. (in English). ["The prey of 132 species of Bembicini (Hymenoptera) that have been studied is reviewed. About three quarters of the species prey on Diptera, and it is believed that fly predation is ancestral in the group. Eleven species make occasional or regular use of other insects as prey in addition to Diptera (Lepidoptera, Hymenoptera, Neuroptera, Odonata, and/or Homoptera), while 21 species of five genera prey on insects of these same five groups with no use of Diptera. It is hypothesized that this represents an evolutionary progression, whereby populations have experienced shortages of dipterous prey in the past and have broadened their sensory focusing to include other groups of flying insects. Behavior initially learned has, over time, been reinforced genetically to produce the currently observed radiation in prey choice within the group." (Author)] Address: Evans, H. E., Dept. Bioagricultural Sciences and Pest Management, Colorado State University, Fort Collins, CO, 80523-1177 USA

2936. Fachgruppe Faunistik und Ökologie Staßfurt (2002): Dr. Joachim Müller zur Vollendung des 60. Lebensjahres. Entomol. Nachr. Ber. 46(3): 207-208. (in German). [Joachim Müller, Magdeburg is one of the leading German odonatologists with a broad interest in entomology, ornithology, and nature conservation. His companions of the Fachgruppe Faunistik und Ökologie Staßfurt compiled some of the essentials of his curriculum vitae as biologist in Sachsen-Anhalt.] Address: not stated.

2937. Ferreira-Peruquetti, P.S.; De Marco, P. (2002): Efeito da alteração ambiental sobre comunidades de Odonata em riachos de Mata Atlântica de Minas Gerais, Brasil. Revista Brasileira de Zoologia 19(2): 317-327. (in Portuguese with English summary). ["Effects of environmental degradation on Odonata community of Atlantic Forest streams from Minas Gerais, Brazil: The effect of riparian deforestation and stream impoundments on an odonate community was studied in areas of surviving Atlantic forest in Vicososa and in Rio Doce State Park (PERD), Marliéria, Minas Gerais, Brazil. During 1997 16 species of Libellulidae, 4 Coenagrionidae, 2 Gomphidae, 2 Calopterygidae, 1 Megapodagrionidae, 1 Aeshnidae and 3 Protoneuridae were collected. In Vicososa, the association of sampled odonates with lotic or lentic systems, and in PERD for areas with or without riparian vegetation were compared. The results suggest that overall odonate taxonomic richness is high in areas without riparian vegetation. This is probably caused by increase of productivity, and the invasion of lentic odonate species." 2938. Forbes, M.R.; Muma, K.E.; Smith, B.P. (2002): Diffuse coevolution: Constraints on a generalist parasite favor use of a dead-end host. *Ecography* 25(3): 345-351. (in English). ["Many evolutionary models and empirical studies of parasite-host interactions consider single species of parasites exploiting single host species. However, many parasites are generalists in that they parasitize more than one host species (often many more) and establish associations with other hosts that cannot be described as true parasitism. We identify such an association, explain how constraints may maintain it, and indicate why such diffuse interactions are deserving of attention. We describe the use of two closely related *Sympetrum* dragonfly species by larvae of the water mite *Arrenurus planus* Marshall. Adults of one dragonfly species are resistant whereas adults of the other species are almost wholly susceptible to *A. planus*. However, *A. planus* attaches as often to the resistant host as it does to the susceptible host species when relative abundance and seasonal timing of adult emergence of both species is considered. We present evidence that mites track the susceptible host and are most active early in the season, when early-emerging unsuitable hosts are also present. Thus, use of resistant hosts appears an unavoidable outcome of constraints promoting discovery and use of susceptible hosts. Such findings have implications for studies of local adaptation and host switching." 2939. Fritz, K. M.; Dodds, W. K. (2002): Macroinvertebrate assemblage structure across a tall grass prairie stream landscape. *Arch. Hydrobiol.* 154(1): 79-102. (in English). ["Stream macroinvertebrates were collected from four intermittent tributaries and two perennial sites within the Kings Creek basin, Konza Prairie Biological Station (KPBS) near Manhattan, KS, USA. The objectives of this study were to assess the roles of disturbances (floods and drying) and refugia on benthic and colonization (drift and aerial) assemblage composition over two years among sites with contrasting hydrologic regimes. Benthic taxa richness and diversity at the perennial headwater site were significantly greater than richness and diversity at intermittent sites, whereas the downstream perennial site did not differ significantly from two of the intermittent sites. The larger magnitude of floods at the downstream perennial site resulted in greater losses in richness than at the upstream intermittent and perennial sites. Both classification and ordination revealed that benthic assemblage composition was more strongly correlated with time since last disturbance and season than with static hydro-logic descriptors, microhabitat measures, or assemblage characteristics (richness or density). Richness of aerial colonization and drift samples collected at intermittent sites was greatest at the site with the nearest upstream perennial surface water. Because Kings Creek is a relatively pristine stream, these data may be useful as a baseline for comparison with future efforts for bioassessment of intermittent prairie streams." (Authors) *Calopteryx maculata*, *Argia plana*, *Archilestes grandis*, and *Erythemis* sp. are listed in tab. 1.] Address: Dodds, W.K., Department of Biological Sciences, Auburn University, Auburn, AL 36849, USA.

2940. Futahashi, R.; Futahashi, H. (2002): A case of female adult of *Anax nigrofasciatus nigrofasciatus* (Aeshnidae) bitten by a last instar larva of the same species. *Tombo* 44: 33. (in Japanese with English summary). ["We observed a female adult of *Anax nigrofasciatus nigrofasciatus* bitten on the tip of abdomen by a last instar larva of the same species. The adult thrashed her wings and finally tried to escape from the predator, but she was injured from the 9th to 10th abdominal segments and was unable to fly." (Authors) This encounter between two different life stages is documented by an informative photo.] Address: not stated in English

2941. Futahashi, R.; Futahashi, H.; Araki, Y. (2002): The odonate fauna of Noto peninsula, Hokuriku District, Honshu. *Tombo* 44: 25-28. (in Japanese with English summary). ["The Odonate fauna in the Noto Peninsula, Ishikawa Prefecture, Hokuriku District, central Honshu, Japan, is outlined based primarily on our recent survey. *Lestes japonica* Selys, 1883 (Lestidae) was found at five ponds (first record from Ishikawa Prefecture). *Soma-tochlora clavata* Oguma, 1913 (Corduliidae) was newly recorded from the peninsula. Consequently, a total of 77 species of 11 families have been recorded from the peninsula. Some zoogeographical comments are given for the following two noteworthy species: *Sympetma paedisca* (Brauer, 1877) (Lestidae) and *Sympetrum speciosum speciosum* Oguma, 1915 (Libellulidae)." 2946. Grand, D. (2002): Voyage en Guadeloupe. *Martinia* 18(1): 29-36. (in French with English summary). [In March 2001, 19 odonate species were recorded on Guadeloupe, Lesser Antilles. 19 taxa are commented in some detail. The rare *Protoneura ailsa*, and taxonomic problems between *Brechmorhoga praecox* and *B. grendadensis* are discussed.] Address: Grand, D., Impasse de la Voûte, F-69270 St. Romain-au-Mont d'or, France

2947. Grimaldi, D.A.; Engel, M.S.; Nascimbene, P.C. (2002): Fossiliferous Cretaceous amber from Myanmar (Burma): Its rediscovery, biotic diversity, and paleontological significance. *American Museum Novitates* 3361: 1-72. (in English). ["Amber from Kachin, northern Burma, has been used in China for at least a millennium for carving decorative objects, but the only scientific collection of inclusion fossils, at the Natural History Museum, London (NHML), was made approximately 90 years ago. Age of the material was ambiguous, but probably Cretaceous. Numerous new records and taxa occur in this amber, based on newly excavated material in the American Museum of Natural History (AMNH) containing 3100 organisms. Without having all groups studied, significant new records and taxa thus far include the following (a dag refers to extinct taxa): [...] Odonata indet. (wing fragment); [...]. The stratigraphic distribution of exclusively Mesozoic arthropods in Burmese amber is reviewed, which indicates a probable Turonian-Cenomanian age of this material (90-100 Ma). Paleofaunal differences between the NHML and AMNH collections are discussed, as is the distinct tropical nature of the original biota. Burmese amber probably harbors the most diverse biota in amber from the Cretaceous, and one of the most diverse Mesozoic microbiotas now known." (Authors)] Address: Grimaldi, D., Amer. Museum Nat. Hist., Dept. Invertebrates, New York, NY 10024 USA

2949. Guerbaa, K.; Barataud, J. (2002): Découverte de *Cordulegaster bidentata* Sélys, 1843 dans le département de la Haute-Vienne (Odonata, Anisoptera, Cordulegasteridae). *Martinia* 18(2): 66. (in French). [Two records of *Thecagaster bidentata* are briefly documented; the species was not known from the Département Haute-Vienne (France) prior May 2001.] Address: Guerbaa, K., 1, rue de la Madonnette, F-87250 Bessines-sur-Gartempe, France

2950. Guerbaa, K. (2002): Les espèces d'odonates "remarquables" du Limousin. *Martinia* 18(1): 3-12. (in French with english summary). [34 species of the Limousin, France are briefly commented; records base on a collection of 15000 species/location made after 1980.] Address: Guerbaa, K., 1, rue de la Madonnette, F-87250 Bessines-sur-Gartempe, France

2951. Ha, L.Y.; Wildermuth, H.; Dorn, S. (2002): Emergenz von *Cordulia aenea* (Odonata: Corduliidae). *Libellula* 21 (1/2): 1-14. (in German with English summary). ["Emergence of *C. aenea* was studied at two ponds in northern Switzerland at 475 m asl in 2000. Emergence started on 27 April and lasted 25 days. The EM50 fell at 8 days for males and 9 days for females. A diel periodicity of emergence with a major peak in the morning was found. The preferred site of emergence was within a strip 5 metres wide along the margin of each pond. Within this strip 99.8 % of the 917 exuviae were found. Exuviae abundance in the 7 sections sampled around the perimeter ranged from 1.4 to 5.5 per metre, depending on the structure of the margin. Both sexes emerged more frequently above dry ground than above water. The sex ratio did not differ significantly from 1 : 1 (48.3 % males). The population size of *C. aenea* emerging from the two ponds in the study year was estimated as 3300 individuals. The spatio-temporal emergence pattern of *C. aenea* is discussed, special emphasis being placed on habitat preferences and comparisons with other corduliid species." (Authors)] Address: Wildermuth, H., Haltbergstr. 43, CH-8630 Rüti, Switzerland. E-mail: hansruedi@wildermuth.ch

2953. Hämäläinen, M. (2002): Notes on the *Libellago* damselflies of the Andaman and Nicobar Islands, with

description of a new species (Zygoptera: Chlorocyphidae). *Odonatologica* 31(4): 345-358. (in English). ["*Libellago blanda* (Hagen) and *L. andamanensis* (Fraser) are removed from synonymy with *L. lineata* (Bur.); they are redescribed in both sexes and compared with *L. lineata*. Recently acquired material from the Nicobar Isls (Camorta and Great Nicobar) reveals that the original type series of *Micromerus blandus* consists of 2 close, but distinct species. A male specimen (in ZMUC) from Nancowry Island is designated as the lectotype of *L. blanda*. Former syntype females from Little Nicobar belong to a new species, described here as *L. balus* sp.n., holotype (deposited at RMNH, Leiden) of which comes from Great Nicobar Island, Campbell Bay area, 24-XII-2000. Males of *L. blanda* and *L. balus* sp.n. differ in the colour pattern of abdomen and in the shape of rhinarium. The status of *L. indica* (Fraser) is briefly discussed." (Author)] Address: Hämäläinen M., Dept Applied Zool., P.O.Box 27, FIN-00014 University of Helsinki, Finland; E-mail: matti.hamalainen@helsinki.fi

2954. Hart, E.A.; Lovvorn, J.R. (2002): Interpreting stable isotopes from macroinvertebrate foodwebs in saline wetlands. *Limnology & Oceanography* 47(2): 580-584. (in English). ["We compared stable-isotope ($\delta^{13}\text{C}$ and $\delta^{15}\text{N}$) and gut-content analyses of macroinvertebrate foodwebs in saline wetlands of the Laramie Basin, Wyoming, USA. Standard assumptions of stable-isotope fractionation between trophic levels (<1 permil for $\delta^{13}\text{C}$, mean of 3.4permil for $\delta^{15}\text{N}$) suggested that zygopteran (damselfly) larvae consumed mainly amphipods. However, the guts of zygopterans contained no amphipods but rather a mix of chironomid larvae and zooplankton. In all wetlands the gut contents of zygopterans indicated that they were secondary consumers (trophic level 3), but enrichment of $\delta^{15}\text{N}$ between zygopterans and their prey ($\Delta\delta^{15}\text{N}$) varied from 1 to 3.4permil between wetlands. In other studies, such variation in $\Delta\delta^{15}\text{N}$ has been interpreted to mean that food-chain length differed between aquatic systems. We review alternative interpretations of variable $\delta^{15}\text{N}$ enrichment, namely, varying C:N ratios in food, differential enrichment between consumer species, and habitat-specific variation of $\delta^{15}\text{N}$ at the base of foodwebs. We also suggest that variation in the timing and rates of nitrogen cycling can affect measured $\Delta\delta^{15}\text{N}$ both within and between foodwebs. For aquatic macroinvertebrates, we urge that stable isotopes be supplemented with independent observations to avoid incorrect conclusions about trophic pathways, trophic levels, and food-chain lengths in different ecosystems." (Authors)] Address: Hart, E.A., Department of Zoology, University of Wyoming, Laramie, WY, 82071, USA. E-Mail: lovorn@uwyo.edu

2955. Hawking, J.H.; Theischinger, G. (2002): Vernacular names for the Australian dragonflies (Odonata). *Austrolestes* 4 (Suppl.): 1-6. (in English). [Checklist of all Australian species with latin and vernacular names, and distributional data (geographic regions).] Address: Hawking, J.H., Murray-Darling Freshwater Research Centre, Cooperative Research Centre for Freshwater Ecology, P.O. 2956. Heidari, H.; Dumont, H.J. (2002): An annotated check-list of the Odonata of Iran. *Zoology in the Middle East* 26: 133-150. (in English with German summary). ["A perusal of the literature and study of some additio-

nal collections leads to a list of 95 species and subspecies of dragonflies for Iran. We claim that at least another 15 Eurosiberian and Oriental species await discovery. Eurosiberian species dominate in the north-west and along the Caspian coast; as one moves south in western Iran, Middle-East endemics become more prominent, and a limited admixture of Afrotropical species occurs. The central desert axis is a zoogeographical break, in which predominantly Irano-Turanian species are found. East of it, Irano-Turanians mix with Oriental elements. The Oriental element is particularly strong along the Makran coast, where, additionally, a short series of species occurs with a full Oriental-Afrotropical range. The Zagros mountains and their extensions in Sistan-Baluchistan facilitate dragonfly dispersal across an otherwise arid area, but have been insufficiently studied. The same is true of the Kopet Dag, which provides a wedge between the Asian deserts, and acts as a filter for Eurosiberian species to reach the high mountains of Afghanistan and, vice versa, allows Me-siatic species to spread west. All these conclusions are at a qualitative level: large parts of Iran are still unstudied, and the mapping of the range of individual species remains to be done. East-west and north-south clines are common in *Calopteryx splendens* and other zygopterans, but remain to be worked out in detail." (Authors) Of some interest are records of *Lestes concinnus*, *Pseudagrion laidlawi*, *Brachytron pratense*, *Libellula quadrimaculata*, *Sympetrum arenicolor*, *S. haritonovi*, and *Zygonyx torridus*.] Address: Dumont, H.J., Univ. Gent, Inst. Animal Ecology, K.L. Ledeganckstraat 35, B-9000 Gent, Belgium. E-mail: Henri.Dumont@rug.ac.be

2957. Heidemann, H.; Seidenbusch, R. (2002): Die Libellenlarven Deutschlands. Die Tierwelt Deutschlands. Teil 72: 328 pp. (in German). [In 1993, H. Heidemann and R. Seidenbusch published a long awaited book on the larvae resp. exuviae of the Odonata occurring in France and Germany. In spite of some shortcomings this was a significant contribution to our knowledge of the larval stage of the Odonata of western Europe. On the fundament of this publication, the authors nearly ten years later publish two revised - a French and a German - editions. The plenty of detailed information makes it very difficult to compare these three editions. More generally spoken, the French edition is more close to the book of 1993, while the German edition appears more original. The French version - which of course includes 11 more species than the German edition - is paperback, while the German version has a solid spine. There are a lot of amendments in detail, even some new plates resp. drawings. From the didactical point of view, the rearrangement of the drawings and the labeling of the drawings (but exclusively in the German version!) improve the useability in a significant way. I personally miss a concept where key and figures are printed close on one page or two opposed pages. Maybe that this is a matter of taste. The scale of the figures was changed in some cases; the printing quality of some of the figures was improved (the labeling is more professional; but e.g. partly missing on plate 7 in the German version). In some cases it will be better to use the 1993-version (e.g. epi- and paraproct of *Pyrrhosoma nymphula*), because the contrast of some of the figures of the first version is better. Without detailing the differences between the two versions - which are original works - the general structure is as follows: Preface, notes for the user, glossar, mor-

phology of the larva, larval ecology, collecting and storing of exuviae, catching and rearing larvae, questions of nomenclature (with some worth reading additions compared with the 1993-version), keys (with extensive additional information on morphological structures, habitats, and distribution), and a selected bibliography. In the framework of nomenclature questions, it is remarkable that *Aeshna subarctica elisbatheae* (Djakonov, 1922) was replaced by the nominate form *A. subarctica* Walker, 1908. I couldn't find any explanation for this. The German edition is written in German, the book on the exuviae of Germany and France in French. Without any doubt, both works are indispensable for field work in Germany and/or France. I think, a forthcoming edition should be improved by separating keys and additional information, and by arranging keys and figures close together. (Martin Schorr) Address: Goecke & Evers, Inh. E. Bauer, Sportplatzweg 5, D-75210 Keltern, Germany. E-mail: www.goeckeevers.de

2958. Heidemann, H.; Seidenbusch, R. (2002): Larves et exuvies des libellules de France et d'Allemagne (sauf de Corse). ISBN 2-9597291-5-0: 415 pp. (in French). [For a review of the work see OAS 2957. The book can be obtained by the SFO for 28 Euro.] Address: Société française d'odonatologie (SFO), 7, rue Lamartine, F-78390 Bois-d'Arcy, France.

2959. Heitz, S. (2002): Libellen der Wiesenbäche und ihre Einbindung in bestehende Planungsinstrumente - am Beispiel von *C. mercuriale* (Helm-Azurjungfer). *mercuriale* 2: 7-13. (in German). 2960. Hellmund, M. Hellmund, W. (2002): Eigelege fossiler Zygoteren auf Dikotylenblättern aus dem Mittelmiozän von Salzhausen (Vogelsberg, Hessen, Deutschland). *Odonatologica* 31(3): 253-272. (in German, with English summary). ["22 specimens of dicotyledon leaves with egg-sets of fossil Zygoptera, originating from a locality NE of Frankfurt/Main, Germany and preserved in SMF, Frankfurt/Main are described, illustrated and discussed. In the past (1846, H.R. Goepfert, Die Gattungen der fossilen Pflanzen, Henry & Cohen, Bonn), these structures were misinterpreted as saprophytes, "Hysterites opegraphoides". The true nature of the sets is apparent from fossil and recent evidence; they are to be attributed to the "coenagrionid type" of oviposition, more particularly to the so-called "Zickzack- und Bogenmodus" mode sensu M. Hellmund & W. Hellmund, 1991 (Stuttg. Beitr. Naturk. [B] 177: 1-17). Here-with the phenomenon is recorded for the first time from the Middle Miocene and the Lower Neogene (age ca 15 mio yr), though this oviposition mode is practised since the Upper Cretaceous times (ca 90 mio yr ago) until present. In some Tertiary localities, e.g. Messel (Hesse) and Hammerunterwiesenthal (Saxony), egg-sets are the only evidence of the Zygoptera occurrence." (Authors)] Address: Hellmund, W., Institut für Geologische Wissenschaften und Geiseltalmuseum, Martin-Luther-Universität Halle-Wittenberg, Domstr. 5, D-06108 Halle (Saale), Germany. 2961. Herkenrath, P.; Evans, M. (2002): Die Mesopotamischen Sümpfe -eine unbemerkte Tragödie. *Ber. Vogelschutz* 38: 157-161. (in German with English sum-

mary). ["The Mesopotamian Marshes in Iraq and Iran, formed by the rivers Euphrates and Tigris, consisted of a range of wetland ecosystems and stretched over an area of 15,000 - 20,000 km². They have been inhabited by the Marsh Arabs with a unique 5,000 year-old culture. For millions of migratory waterbirds and raptors, the Marshes formed one of the most important wintering areas along the West Siberian-Caspian-Nile flyway. The Marshes also harboured globally significant breeding populations of a number of rare and threatened species. Two bird and several other vertebrate species are strictly endemic to the area. 32 large dams in Turkey, Iraq, Iran and Syria have considerably reduced the water flow and changed the sedimentation regime of Euphrates and Tigris while more dams are being planned or under construction. Huge drainage schemes by the Iraq government, especially in the 1990s, have left only some 14.5% of the area of the marshes, as of May 2001. Desertification with the subsequent formation of salt deserts is widespread. The Marsh Arabs were forced to leave their land and to abandon their traditional way of living. [...]. The United Nations Environment Programme (UNEP) has developed a set of recommendations for the regeneration of the Marshes." (Authors) The marshes also harbour a population of *Brachythemis fuscopalliata*; this species is assessed by the authors as "globally endangered" and "a regional endemic species".] Address: Herkenrath, P.; Evans, M.; BirdLife International, Wellbrook Cowl, Girton Road, Cambridge CB3 0NA. 2965. Hori, S.; Yokoyama, T. (2002): *Boyeria mac-lachlani* from Noboro Forest Park. *Bull. Hokkaido Odonatological Society* 14: 4-5. (in Japanese). [Records from September and October 2001 are discussed.] Address: Yokoyama, T., 1-15-303, Higashi 22chome, Kita 19jo, Higashi-ku, Sapporo City, 065, Japan

2966. Hovmöller, R.; Pape, T.; Källersjö, M. (2002): The Palaeoptera problem: Basal pterygote phylogeny inferred from 18S and 28S rDNA sequences. *Cladistics* 18(3): 313-323. (in English). ["Monophyly of the pterygote insects is generally accepted, but the relationships

among the three basal branches (Odonata, Ephemeroptera and Neoptera) remain controversial. The traditional view, to separate the pterygote insects in Palaeoptera (Odonata + Ephemeroptera) and Neoptera, based on the ability or inability to fold the wings over the abdomen, has been questioned. Various authors have used different sets of morphological characters in support of all three possible arrangements of the basal pterygote branches. We sequenced 18S and 28S rDNA from 18 species of Odonata, 8 species of Ephemeroptera, 2 species of Neoptera, and 1 species of Archaeognatha in our study. The new sequences, in combination with sequences from GenBank, have been used in a parsimony jackknife analysis resulting in strong support for a monophyletic Palaeoptera. Morphological evidence and the phylogenetic implications for understanding the origin of insect flight are discussed." (Authors)] Address: Hovmöller, R., Department of Zoology, Stockholm University, Stockholm Sweden

2967. Hunger, H. (2002): Anwendungsorientiertes Habitatmodell für die Helm-Azurjungfer (*Coenagrion mercuriale*, Odonata) aus amtlichen GIS-Grundlagendaten. *Natur und Landschaft* 77(6): 261-265. (in German with English summary). ["A GIS-based habitat model was developed for *C. mercuriale*, a species considered to be 'under immediate threat of extinction' in Germany's Red List of endangered species and listed in Annex II of the European Union Habitats Directive. ATKIS land-use data and a groundwater model were used as thematic layers. Occurrences of *C. mercuriale* in the 'Freiburger Bucht' study area (SW-Germany) were mapped. Following this, a preference analysis was performed. The results showed that, within the study area, the species prefers sections of watercourses that are situated within areas characterized by high groundwater levels. Within arable lands, this preference was distinct up to a groundwater depth of one metre, in grassland up to a depth of 2 metres. The model produced results that are consistent with 'intuitive expert knowledge'. It uses basic geodata which are available at nature conservation agencies. It uses few parameters, which, however, appear to be key factors. Therefore it belongs to a 'new generation' of habitat models with a strongly applied focus. This type of model is in increasing demand for applied nature conservation purposes and planning issues. In 2001 and 2002, the model is being evaluated in an even larger study area." (Author)] Address: Hunger, H., Institut für Naturschutz und Landschaftsanalyse (INULA), Am Pfahlgraben 8, D-79276 Reute, Germany

2968. Hutchings, G. (2002): Three new species of Odonata for Saskatchewan, Canada. *Argia* 13(4): 5-7. (in English). [In June and July 2001, *Basiaeschna janata*, *Somatochlora walshii*, and *S. williamsoni* were discovered. Habitats and co-occurring species are described resp. listed.] Address: Hutchings, G., 971 Arundel Drive, Victoria, British Columbia, V9A-2C4, Canada. E-mail: sea-trek@islandnet.com

2969. Inoue, K. (2002): Report of the 15th International Symposium of Odonatology held in Novosibirsk, Russia. *Argia* 13(4): 3-4. (in English). [This report gives some information on the symposium, with records of species made during the field trips, and the announcement of the 16th symposium to be held in Schwerin, Germany. Of some interest is the note that *Calopteryx virgo* (records from Siberia and Amur-region) is con-

specific with *C. japonica*.] Address: Inoue, K., 5-9 Fuminosato 4-chome, Abeno-ku, Osaka 545, Japan

2970. InsectLine (2002): Insects reported during the early part of 2002. *Atropos* 16: 74-75. (in English). [*Pyrrhosoma nymphula* was on the wing in April at several sites.] Address: not stated

2971. Irineu de Souza, L.O.; Costa, J.M.; Espindola, L.A. (2002): Description of the last instar larva of *Oligoclada laetitia* Ris, 1911 and comparison with other Libellulidae (Anisoptera). *Odonatologica* 31(4): 403-407. (in English). [Specimens of *O. laetitia* from Pantanal Sul-Mato-Grossense, Brazil are illustrated, described and compared with other genera of Libellulidae possessing dorsal hooks on abdominal segments VIII-X: *Dythemis*, *Macrothemis*, *Perithemis*, *Planiplax*, and *Tauriphila* (in part).] Address: Costa, J.M., Departamento de Entomologia, Museu Nacional, Universidade Federal do Rio de Janeiro, Quinta da Boa Vista, São Cristóvão, BR-20942-040 Rio de Janeiro, Brazil. E-mail: jcosta@unisis.com.br

2972. Jacquemin, G.; Boudot, J.-P. (2002): Les Odonates des tourbières et lacs acides du massif vosgien: bilan de dix années de prospection. *Martinia Hors Série* 4: 27-38. (in French with English summary). [The odonate fauna of 66 peat bogs and 36 peaty lakes in the Vosges mountains (Eastern France) is reported. "One erratic and 48 indigenous species were observed. *Somatochlora alpestris* and *Aeshna subarctica elisabethae* were found to be confined above 700 m a.s.l., 7 species to occur whatever the altitude, and 17 taxa to occur under 500 m a.s.l."] Address: Jacquemin, G., Biologie des Insectes, Université H. Poincaré, Nancy 1, BP 239, F-54506 Vandoeuvre-lès-Nancy, France

2973. Jödicke, R. (2002): Nachruf auf Joachim Wenzinger (1. Oktober 1944 -12. Dezember 2001). *Libellula* 21(1/2): 71-76. (in German, with English summary). ["In odonatological circles the German zoologist and journalist was highly regarded, especially owing to his long-term studies on *Ophiogomphus cecilia*. A short biography is followed by a list of his Odonatological publications." (Author)] Address: Jödicke, R., Großenging 14, D-49699 Lindern, Germany. E-mail: r.joedicke@t-online.de

2974. Johansson, F. (2002): Reaction norms and production costs of predator-induced morphological defences in a larval dragonfly (*Leucorrhinia dubia*: Odonata). *Canadian Journal of Zoology* 80(5): 944-950. (in English). ["To understand the evolution and ecology of inducible defence we need to understand the genetics and costs underlying this phenomenon. It has been suggested that the abdominal spines of odonate larvae work as a defensive trait, and that the presence of fish predators induces the production of longer abdominal spines. This study was designed to answer the following questions: (i) What is the shape of the reaction norms of spine length in the larvae of the dragonfly *Leucorrhinia dubia* reared in the presence and absence of fish? (ii) Does the production of longer spines imply that production costs are incurred in terms of development time or size? I performed a laboratory experiment in which I raised 30 families of *L. dubia* larvae in the presence and absence of fish. In general, the presence of fish induced the production of longer abdominal spines in the larvae, and there was a genotype X environment interaction, suggesting the potential for evolution

of plasticity of the traits. No production costs could be found with respect to development time and size at final instar." (Author)] Address: Johansson, F., Department of Ecology and Environmental Science, Animal Ecology Group, Umea University, 90187 Limed, Sweden. E-mail: frank.johansson@eg.umu.se

2975. Johnson, J.; Cooms, E.; Valley, S. (2002): Recent highlights in Oregon. *Argia* 14(2): 11-13. (in English). [Oregon, USA; new findings total the Oregon Odonata to 88 species: *Lestes stultus*, *Nehalennia irene*, *Aeshna subarctica*, *A. sitchensis*, and *Paltothermis lineatipes*. In addition "other interesting records" are: *A. walkeri*, *Somatochlora minor*, *S. semicircularis*, *S. walshii*, and *Libellula comanche*. The habitats/localities of the species are discussed in some detail.] Address: Johnson, J., 6303 SE Ramona Street, Portland OR 97206-5930, USA. E-mail: jimjohn@teleport.com

2976. Juillerat, J. (2002): Emergence, mobilité et milieu reproduction chez *Orthetrum coerulescens* (Odonata, Libellulidae) dans le Jura et le Jura bernois. *Nachrichten des Schweizer Zentrums für Kartographie der Fauna* 24: 14. (in French). [Verbatim: Travail de diplôme de Laurent Juillerat, Institut de zoologie, Université de Neuchâtel L'Orthétrum bleuissant (*Orthetrum coerulescens*) est une libellule qui, dans le Jura, se reproduit avant tout dans des marais de pente pâturés par le bétail. La principale menace qui plane sur ses populations est le drainage de ses milieux de reproduction. Dans une logique de conservation, ce travail a démontré qu'un piétinement mesuré des marais par le bétail est favorable à l'espèce, puisqu'il crée les gouilles dans lesquelles elle se reproduit. Il ne peut toutefois dépasser un certain seuil, un piétinement trop intense conduisant à la destruction pure et simple des marais. Près de 600 libellules ont été capturées et marquées entre le 27 mai et le 30 août 2001 dans trois vallées du Jura central. Ce travail a permis d'estimer la durée de vie maximale des adultes à près de 70 jours, ce qui dépasse largement les chiffres jusqu'alors avancés pour l'espèce (32 jours) ; de démontrer que la durée de la période de maturation des adultes était fortement influencée par les conditions météorologiques et qu'elle était plus importante chez les femelles ; de mettre en exergue de fréquents déplacements entre les différents marais d'une même vallée, la distance maximale étant de 1600 m. Cependant, aucun déplacement entre les différentes vallées n'a pu être mis en évidence.] Address: not stated

2977. Kalkman, V.J.; Duinen, G.A. van; Esselink, H.; Kuper, J.T. (2002): New records of Odonata from Estonia, with notes on breeding in the Baltic Sea and on species assemblages of raised systems. *Notul. odonatol.* 5(10): 120-125. (in English). [The records (1-21 July 1999, 14-24 July 2000) of 42 spp. resulting from 32 localities are presented. Records of *Lestes virens*, *Coenagrion johanssoni*, *C. puella*, *Pyrrhosoma nymphula*, *Aeshna ossiliensis*, *A. subarctica*, *Anax imperator*, *Somatochlora arctica*, and *Libellula fulva* are discussed in detail. *Ischnura elegans*, *Enallagma cyathigerum*, and *Orthetrum cancellatum* were found breeding in the Baltic Sea. It is concluded that the northward extension of the ranges of *I. elegans* and *O. cancellatum* in the Baltic region is influenced by their concurrence in brackish habitats along the Baltic Sea. Waterbodies in different parts of intact raised bog systems could be distinguished by differences in species assemblages and species

richness. In this context *Leucorrhinia rubicunda* and *L. caudalis* are briefly discussed.] Address: Kalkman, V.J., Oude Rijnsburgerweg 28, NL-2342 BC Oegstgeest, The Netherlands. E-mail: Kalkman@naturalis.nnm.nl

2978. Kalkman, V.J.; Smit, J.T. (2002): *Platycnemis subdilatata* Sel., new to the Canary Islands? (Zygoptera: Platycnemididae). *Notul. odonatol.* 5(10): 128. (in English). [A specimen in the collection of the Zoological Museum of Amsterdam with label information on Tenerife is discussed in detail. It is concluded that the origin of the specimen lies in the Sahara from where it was wind dispersed. A less probable explanation is that it was transported by a vessel.] Address: Kalkman, V.J., Oude Rijnsburgerweg 28, NL-2342 BC Oegstgeest, The Netherlands. E-mail: Kalkman@naturalis.nnm.nl

2979. Kano, K. (2002): Microhymenopteran insects phoretic on adult female of *Gynacantha ryukyurnis*. *Tombo* 44: 21-22. (in Japanese with English summary). [Tenjinny, Nago City, Okinawa-jima Island, Japan; on 1-VII-2001 a micro-hymenoptera was photographed sitting on the thoracic dorsum near the basal part of the wings of *G. ryukyurnis*.] Address: Kano, K., 5-19-17-01, Koishikawa, Bunkyo-ku, Tokyo, 112-0002, Japan

2980. Kano, K.; Kobayasi, F. (2002): Some behaviors of *Rhipidolestes asatoi* Asahina. *Tombo* 44: 19-20. (in Japanese with English summary). [*R. asatoi* was found at Nakakosiki Island, Japan, an island never investigated prior 2001 (?). Photographs document the habitat and some behaviours.] Address: Kano, K., 5-19-17-01, Koishikawa, Bunkyo-ku, Tokyo, 112-0002, Japan

2981. Karube, H. (2002): A new record of *Boninthemis insularis* (Matsumura) from Kitaiwo-jima Island. *Tombo* 44 : 7-8. (in Japanese with English summary). [*B. insularis* was considered as an endemic species from the Ogasawara Islands, Japan. 20/21 June 2001 it was recorded from the Kita-Iwojima Island of the Kazan-retto Group, app. 175 km SSE of the Ogasawara Islands.] Address: Karube, H., Kanagawa Prefect. Mus. Nat. Hist., 499 Iryuda, Odawara, Kanagawa, 250, Japan

2982. Karube, H. (2002): A new record of *Philosina alba* Wilson from Laos. *Tombo* 44 : 5-6. (in Japanese with English summary). [Prior this record from Laos (1 male, Lak Sao, Vietnam border, 30.IV.1995, S. Nakamura leg.), the species has only been known from the type locality Guandong, China.] Address: Karube, H., Kanagawa Prefect. Mus. Nat. Hist., 499 Iryuda, Odawara, Kanagawa, 250, Japan

2983. Karube, H. (2002): New records of *Archineura hetaeroides* (Fraser) (Calopterygidae) from northern Vietnam with collecting data from Laos. *Tombo* 44 : 6-7. (in Japanese with English summary). [Specimens from Vietnam and Laos are illustrated. The Vietnam specimens have larger milky white maculation on both fore and hind wing than the Laos specimens. The differences are considered as geographical variation.] Address: Karube, H., Kanagawa Prefect. Mus. Nat. Hist., 499 Iryuda, Odawara, Kanagawa, 250, Japan

2984. Karube, H. (2002): Notes on the Chinese *Planaeschna* (Odonata: Aeshnidae) deposited in the Natural History Museum, London, with description of a new species from southern China. *Tombo* 44: 1-5. (in English). [*Planaeschna gressitti* spec. nov., holotype male, Yim Na San, 650 m asl., Kwangtung, China, 15.VI.

1936, J.L. Gressitt leg., holotype deposited in NHML. The species is closely related to *P. tamdaoensis* of northern Vietnam. *P. suichangensis* from Fujian is redescribed.] Address: Karube, H., Kanagawa Prefect. Mus. Nat. Hist., 499 Iryuda, Odawara, Kanagawa, 250, Japan

2985. Kipping, J. (2002): Dragonfly research in the Okavango Delta, Botswana. IDF-Report 4(1): 18-26. (in English). [Between April and August 2000, Odonata were studied on West Chief's Island as well as on the Boro and Thamalakane River in Maun, Botswana, in the southeastern range of the Okavango delta. Furthermore, the author joined an excursion to the Panhandle around Mohembo and Shakawe during the first week of June. A total of 72 odonate species is listed without further comments. IDF and WdA promoted this study; more extensive results of the study will be published in the Int. Jour. Odonatology.] Address: Kipping, J., Ringstr. 5/6, D-04600 Altenburg, Germany. E-mail: jenskiping@hotmail.com

2986. Kita, H. (2002): Notes on the situation of the dying aged female of *Epiophlebia superstes* (Selys) in ovipositing in the field. Tombo 44: 23-24. (in Japanese with English summary). ["The author observed an aged female of *E. superstes* trying to lay eggs into a hard twig for oviposition. The female was, however, unable to lay eggs into the twig, and after 1 hour and a half, she dropped onto the river water. Dissection of her abdomen revealed no eggs inside." (Author)] Address: Kita, H., Takiyama 6-2-15-308, Higashikunime City, Tokyo, 203-0033, Japan (probably not the actual address)

2987. Kitt, M.; Werth, C. (2002): Libellen in der Bruchbach-Otterbachniederung. Pollichia-Kurier 18(3): 27-29. (in German). [The paper reviews records of Odonata from the Bienwald region near the German-French border in Rheinland-Pfalz, Germany previously published by M. Kitt or M. Niehuis. In the framework to re-establish the White Stork (*Ciconia ciconia*) in this region, numerous little water bodies have been created. These were surveyed by Christine Werth (University of Karlsruhe) with special emphasize to water chemistry, Amphibians, and Odonata (Ms thesis). The odonatological results are very briefly outlined, and a list of species including older and new records is compiled.] Address: Kitt, M., Raiffeisenstr. 39, D-76872 Minfeld, Germany, E-mail: MKitt@tonline.de; Werth, Christine, Mittelberg 4, D-76571 Gaggenau, Germany

2988. Klaus, D. (2002): Bericht über die Tagung Sächsischer Entomologen im Jahre 2002. Mitt. sächs. Ent. 60: 31-33. (in German). [Thomas Brockhaus gave a status quo report on the planned Odonata-fauna of Sachsen.] Address: Klaus, D., Heimstätten 10, D-04571 Rötha, Germany

2989. Klausnitzer, B. (2002): Libellen jagen schwärmende Ameisen - eine ältere Literaturangabe (Odonata). Ent. Nachr. Ber. 46(2): 134. (in German). [In 1897, Alexander Reichert published a paper "Aeschna cyanea MÜLL. und Formica rufa L." in the Entomologische Jahrbuch von Krancher 7: 190. He described a feeding aggregation of *A. cyanea* preying on swarming *F. rufa*. This paper is documented as verbatim.] Address: Klausnitzer, B., Lannerstr. 5, D-01219 Dresden, Germany

2990. Klein, J.-P. (2002): *Leucorrhinia pectoralis* (Große Moosjungfer) im Elsass. mercuriale 2: 13-16. (in German with French summary). [In 2000 and 2001, new localities of *L. pectoralis* in eastern France were traced. The habitats are described in detail along with a compilation of ancient and present known localities in Alsace.] Address: Klein, J.-P., Laboratoire d'Analyses et de Biologie Médicales Aubert, 22, rue des Carnes, F-54063 Nancy, France. E-mail: jpklein@free.fr

2991. Knaus, P.; Wildermuth, H. (2002): Site attachment and displacement of adults in two alpine metapopulations of *Somatochlora alpestris* (Odonata: Corduliidae). International Journal of Odonatology 5(2): 111-128. (in English). ["Site attachment and displacement of adult *S. alpestris* were studied by means of mark-release-resighting during two years at two clusters of ponds (A, B) ca 8 km distant from each other on opposite slopes of Prattigau Valley in the Swiss Alps. Data on 127 marked teneral in 1998 and 92 in 2000 at (A) were obtained. Additionally, in 1998, 187 and in 2000, 23 matures were marked at (A) and 162 at (B). No marked individuals were detected during the pre-reproductive period in the surroundings of the breeding sites. 14.0% of the males and 7.1% of the females marked as tenerals in 1998 were resighted at water subsequently. In 2000 the corresponding resighting rate was significantly lower due to a cold spell (4.0% and 2.4%, respectively). Only one male was resighted for the first time at its emergence pond. The resighting rates of marked adults at (A) were 59.2% (males) and 28.6% (females) in 1998, but only 5.6% and 0% in 2000, respectively. The corresponding resighting rates at (B) in 2000 amounted 27.1% (males) and 9.1% (females). Site attachment and displacement during the reproductive period differed between the two study sites. At (A) site attachment was modest and limited to the largest ponds. Many individuals shuttled between neighbouring ponds and some did so between waters distant up to 2 km from each other. Individuals at (B) exhibited stronger site attachment than at (A) with many being recorded exclusively at their marking water. No marked dragonfly was found to cross the main valley. We conclude that differences in site fidelity and displacement between the localities are due to weather conditions (affecting survival probability), population density (influencing competition) and separation of ponds by forest (inhibiting commuting flights)." (Authors)] Address: Wildermuth, H., Haltbergstr. 43, CH-8630 Rüti, Switzerland. E-mail: hansruedi@wildermuth.ch

2992. Knijff, G. de.; Anselin, A.; Goffart, P. (2002): The Belgium Odonata Atlas Project: changes in distribution. Bull. Inst. Roy. Scien. Nat. Belg. 72 (Suppl.): 111-112. (in English). [The paper abstracts the results of the atlas-activities of the Belgian odonatologists which started in 1983. On the basis of a distribution map presenting data since 1990 the species turn-over with special emphasize to southern species is discussed, and some large scale distribution patterns are outlined.] Address: Knijff, G. de, Instituut voor Natuurbehoud, Kliniekstraat 25, B-1070 Brussel, Belgium. E-mail: geert.de.knijff@instnat.be

2993. Koel, T.M.; Stevenson, K.E. (2002): Effects of dredge material placement on benthic macroinvertebrates of the Illinois River. Hydrobiologia 474(1-3): 229-238. (in English). ["Since the 1930s, dredge material has been removed from the Illinois River and placed a-

long the main channel border in shallow depths to maintain a 2.7 m deep main channel for commercial navigation. Placement of this material changes the sediment composition from primarily silt/clay to primarily sand, and it buries pre-existing benthic invertebrates. During 1997 and 1998, the benthos of an 125 km reach of the middle Illinois River (La Grange Reach) was studied by extracting 1065 Ponar samples from randomly-selected sites which had never received dredge material, received dredge material one year previous, or received dredge material during the current year. Although total numbers of macroinvertebrates collected was lower in 1998 than in 1997, relative abundances of eight targeted taxa were highly similar between years. Chironimidae were most abundant and comprised >66% of all macroinvertebrates collected both years. Differences in densities of Chironomidae, Ephemeroptera, Sphaeriidae, Corbicula fluminea (Müller, 1774), Dreissena polymorpha (Pallas, 1771), Odonata, and Gastropoda among the three classes of dredge material placement were all significant ($P < 0.05$). For all taxa, densities were highest at sites that had never received dredge material; and, for all taxa except Chironimidae, densities were lowest at sites that received dredge material during the current year. No significant recovery by macroinvertebrates was noticed on dredge areas of this reach after one year ($P > 0.05$). Future operations to maintain a channel for navigation should consider pre-existing densities of macroinvertebrate taxa. Because benthic macroinvertebrates are an important component of the food web and shifting sand does not support diverse macroinvertebrate communities, strategic placement of dredge material by avoiding islands or other areas of high macroinvertebrate diversity could improve overall system productivity and biotic integrity of large river-floodplains." (Authors)] Address: Koel, T.M., Illinois Natural History Survey, LTRMP Havana Field Station, 704 N. Schrader Ave, Havana, IL 62644, U.S.A. Present address: Center for Resources, P.O. Box 168, Yellowstone National Park, WY 82190, U.S.A. E-mail: toddkoel@nps.gov

2994. Korkeamäki, E.; Suhonen, J. (2002): Distribution and habitat specialization of species affect local extinction in dragonfly Odonata populations. *Ecography* 25(4): 459-465. ["The object of our study was to determine the effect of distribution and habitat specialization of odonate species on local extinction in streams in central Finland. We studied the local extinction of the 20 most abundant dragonfly (Odonata) species in 34 small creeks and brooks in central Finland. The historical presence of each studied species in our research area was confirmed using existing records gathered between 1930 and 1975. A minimum of five records was available for each species. During the summers of 1995 and 1996, we investigated the current persistence of 219 separate populations with historical presence. In total, 98 historical populations were vanished. As predicted, we found that species with a narrow distribution were less persistent than species with a broad distribution. Therefore, the extinction risk of a species was inversely related to the width of its regional distribution. Using reference works, species were categorized into two main breeding habitat types: lotic species or lentic species. The species main habitat type was a significant predictor of local extinction risk after statistical removal of the effect of regional distribution on extinction risk. The lotic species had lower local extinction risk than other species. Altogether, the highest extinction

risk was found in habitat-specialist species associated with peatlands, probably due to loss of natural breeding habitat. On the other hand, extinction risk was lower in widely distributed habitat generalist species than true lotic species. The local extinction within species was more common in small dynamic upstream than in larger stable downstream habitats. The results of this study are consistent with meta-population theory." (Authors)] Address: Korkeamäki, E., Karkunkatu 18 a 4 b, FIN-48600 Karhula, Finland

2995. Krokalo, L.A.; Davydenko, E.V. (2002): Notes on dragonflies (Insecta: Odonata) of Dnipropetrovsk region. *Ecology & Noospherology* 11(1-2): 91-94. (in English with Russian and Ukrainian summaries). [In August 2000, in the environs of the village Andryvka, Novomoskov district, Ukraine (45°15'N 35°00'E), 14 odonate species have been recorded. This enlarges the number district species to 21. Feeding aggregation of *Aeshna mixta* is briefly described.] Address: not stated

2996. Krotzer, S. (2002): *Gomphus septima* rediscovered in Alabama. *Argia* 14(2): 10. (in English). [Bibb County, Alabama, USA, 5 May 2002] Address: Krotzer, S., 6010 Woodvale Drive, Helena, AL 35080, USA. E-mail: smjkrotzer@aol.com

2997. Kuhn, J. (2002): *Sympetrum meridionale* am Schmiechener See, Schwäbische Alb: Entwicklungsnachweis und Habitate (Odonata: Libellulidae). *Libellula* 21(1/2): 57-63. (in German, with English summary). ["On 1 August 2000 six newly emerged individuals were recorded at the shallow lake "Schmiechener See" (9°44'E, 48°21'N; altitude 534 m, which oscillates strongly and irregularly in water-level. Habitats were a meadow and a ploughed field, both temporarily flooded and maintained for conservation purposes. The presence and abundance of Mediterranean dragonfly species at the "Schmiechener See" strongly increased during 1980-2001." 2999. Lange, M.; Hofmann, T. (2002): Zum Beutespektrum der Rohrweihe *Circus aeruginosus* in Mecklenburg-Strelitz, Nordost-Deutschland. *Vogelwelt* 123: 65-78. (in German with English summary). ["Between 1995 and 1997 prey remains and pellets were collected from 61 Marsh Harrier nests in Mecklenburg Strelitz (North-east Germany) in order to study the diet composition. Seventy-six species of vertebrates (53 birds species, 14 mammals species) and 38 insect taxa were identified. Species numbers and proportions of prey types differed significantly between prey remains at the nest and pellets. Birds made up 63% of all prey remains but constituted only 23% in pellets where mammals

proved to be dominant with a content of 75% (prey remains 23%). [...] The determination of insect remains turned out to be a special problem and their origin in pellets could not always be accurately solved. Coleoptera, especially carabids, dominated with 87%. [...] Each one unidentified Anisoptera and Zygoptera could be found in the pellets too.] Address: Lange, M., F.-Mehring-Str. 20, D-17489 Greifswald, Germany. E-mail: morgus.lange@gmx.de

3004. Loman, J. (2002): *Rana temporaria* metamorph production and population dynamics in the field Effects of tadpole density, predation and pond drying. *J. Nat. Conserv.* 10: 95-107. (in English). ["This study investigates factors of importance for tadpoles survival and metamorph production in the common frog *R. temporaria*. It also assesses the importance of this for the population dynamics of the species. Eighteen ponds were studied for up to 8 years. Data collected each year included: number of spawn clumps deposited, tadpole number and metamorph number. The permanency of the ponds was also recorded each year. Measures were taken of predator density. There was no suggestion of density dependence in the survival of tadpoles. In contrast, the number of spawn clumps deposited per pond area was highest for ponds with high survival.

Density of predators (sticklebacks, newts and invertebrates [including "larval Anisopteran"]) was negatively correlated to tadpole and metamorph survival. This was true both within (among years) and among ponds. Several of the study ponds dried completely before metamorphosis in some years. However, those ponds also were those with the smallest number of predators and in years with successful metamorphosis, these ponds produced more metamorphs than more permanent ponds. An analysis of the year to year dynamics showed that population size (number of deposited spawn clumps) was correlated to that in the previous year, suggesting a fairly high adult survival, but also on the number of metamorphs emerging two or three years before (corresponding to the age of sexual maturity of the species). It is concluded that the aquatic stage is not strongly limiting in these ponds but conservation efforts should be focused on the terrestrial habitat. Also, the study stresses the value of temporary ponds, despite the fact that recruitment often fails totally in these." 3005. Lopez, R. (2002): X-50 Dragonfly poised for takeoff. *Aerospace America* 40(4): 30-34. (in English). [Although designed as a vertical takeoff and landing aircraft, the Dragonfly will be able to achieve much higher forward speeds than conventional manned helicopters. Its design combines the low disk-loading hover efficiency and low-speed flight characteristics of a helicopter with the high subsonic cruise speed of a fixed-wing aircraft. This new developed aircraft obviously integrates some of the flight characteristics of the Anisoptera, and this may be a reason to name it "Dragonfly".] Address: not stated

3006. Lotzing, K. (2002): Die aktuelle Libellen-Fauna (Odonata) der Bergbaufolgegewässer im Bereich der Egelner Mulde innerhalb der Bodeniederung des Landkreises Aschersleben-Staßfurt (Sachsen-Anhalt). *Entomologische Nachrichten und Berichte* 46(2): 85-89. (in German with English summary). [Prior brown coal mining, which started in the first half of 20th century, the region was quite poor in water bodies. This situation changed significantly after ceasing mining activities: the excavations filled with groundwater, and in some cases interesting habitats developed. The Odonata were studied between 1980 and 2001 intensively. A total of 31 species including species of regional interest could be traced: *Calopteryx splendens*, *Lestes barbarus*, *L. dryas*, *L. virens*, *Erythromma viridulum*, *Aeshna affinis*, *Anaciaeschna isosceles*, *Anax parthenope*, *Libellula fulva*, and *Sympetrum pedemontanum*. In addition, records of *Lestes barbarus*, *Erythromma viridulum*, *Brachytron pratense*, *Aeshna affinis*, and *Sympetrum flaveolum* should be mentioned too. The species are listed for each of the 15 surveyed waterbodies, and are zoogeographically classified.] Address: Lotzing, K., Am Hollschen Bruch 4c, D.39435 Unseburg, Germany

3007. Luglia, M.; Luglia, T. (2002): Comptage de larves d'*Aeshna cyanea* (Müller, 1764). *Martinia* 18(1): 28. (in French). [273 larvae of *A. cyanea* were recorded in a small bassin near Sault, Vaucluse, France. The habitat is characterised.] Address: Luglia, M.; Luglia, T., La Fontaine de Durefort, F-84390 Saint Jean de Sault, France

3008. Machado, A.B.M. (2002): Description of *Lauro-macromia flaviae* spec. nov., with notes on the holotype of *L. luismoojeni* (Santos) (Anisoptera: Corduliidae). *Odonatologica* 31(3): 313-318. (in English). [*L. flavia* sp. n. (male holotype: Jaboticatubas, Minas Gerais, Brasil, 14-1-1975; deposited in Author's collection), is described, illustrated, and compared with the males of the two congeners *L. luismoojeni* and *L. dubitalis*. Some amendments are made on the original description of *L. luismoojeni*, based on the examination of the holotype.] Address: Machado, A.B.M., Departamento de Zoologia, Inst. Cienc. Biol., Universidade Federale de Minas Gerais, Caixa Postal 486, 31270-901 Belo Horizonte, Minas Gerais, Brazil

3009. Manteifel, Y.B.; Reshetnikov, A.N. (2002): Avoidance of noxious tadpole prey by fish and invertebrate predators: Adaptivity of a chemical defence may depend on predator feeding habits. *Archiv für Hydrobiologie* 153(4): 657-668. (in English). ["We conducted laboratory experiments where different types of predators were allowed to prey on noxious versus non-noxious tadpoles. The introduced fish *Perccottus glenii* showed prey selectivity: while actively consuming all seized tadpoles of *Rana arvalis* and *Rana temporaria*, it consumed significantly fewer *Bufo bufo* tadpoles. When a *Bufo* tadpole was seized, it was frequently rejected after intraoral testing without much damage done to the tadpole. Nymphs of the dragonfly *Aeshna cyanea*, chewing captured prey, also consumed significantly more tadpoles of *Rana* spp. than *Bufo*. Seized *Bufo* tadpoles were as a rule released seriously damaged. The *Aeshna* readily caught the next *Bufo* tadpole. On the contrary, larvae of the diving beetle *Dytiscus marginalis*, who suck out their prey, did not reject *Bufo* tadpoles. Hence, the relative unpalatability of the *Bufo* tadpoles may provide them with a satisfactory defence against *Perccottus*, an incomplete defence against *Aeshna*, and no protection against *Dytiscus*. It is possible that the relative unpalatability of *Bufo* tadpoles increases their population mortality in ponds with high *Aeshna* density." (Authors)] Address: Manteifel, Y.B., A. N. Severtsov Institute of Ecology and Evolution, Russian Academy of Science, Leninsky pr. 33, Moscow, 117071, Russia. E-mail: sevin@orc.ru

3010. Mashaal, M. (2002): *Somatochlora metallica* (Vander Linden, 1825), espèce nouvelle pour la Corse (Odonata, Corduliidae). *Martinia* 18(1): 25-27. (in French with English summary). [*Somatochlora metallica meridionalis* was recorded on 13 July, 2001 app. 15 km SE of Ajaccio, Corsica, France. Habitat and taxonomic status are discussed.] Address: Mashaal, M., 89 avenue Emile Zola, F-75015 Paris, France. E-mail: mashaal@club-internet.fr

3011. Matushkina, N.; Gorb, S. (2002): Stylus of the odonate endophytic ovipositor: A mechanosensory organ controlling egg positioning. *Journal of Insect Physiology* 48(2): 213-219. (in English). ["Using light and scanning electron microscopy, a sensory field consisting of 15-20 campaniform sensillae is described on the base of the stylus of the endophytic ovipositor of Odonata. It is hypothesised that two symmetric styli equipped with this number of sensillae can function as a mechanosensory organ responsible for control of precise egg positioning in plant stems during oviposition. In laboratory experiments with females of *Lestes sponsa* and *L. barbarus*, it was demonstrated that the distance

between laid eggs is not dependent on the presence of styli. Removal of styli from both sides did not influence a shift of oviposition to one side. Females with one removed stylus shifted the clutch line in the opposite direction toward the removed stylus. Additionally, removal of styli influenced positions of single eggs in egg sets, and disturbed the capacity for complex oviposition. Thus, both morphological and experimental data support the hypothesis that styli participate in the control of egg line and egg patterning in the clutch." (Authors)] Address: Gorb, S., Max-Planck-Institut für Entwicklungsbiologie, Spemannstr. 35, D-72076 Tübingen, Germany. E-mail: stas.gorb@tuebingen.mpg.de

3012. May, M.L.; Baird, J.M. (2002): A comparison of foraging behavior in two "percher" dragonflies, *Pachydiplax longipennis* and *Erythemis simplicicollis* (Odonata: Libellulidae). *Journal of Insect Behavior* 15(6): 765-778. (in English). ["Feeding behaviors of two adult libellulid percher dragonflies, *Pachydiplax longipennis* and *Erythemis simplicicollis*, were compared. All results pertain to feeding from natural perches located some distance away from reproductive rendezvous sites. Compared to *P. longipennis*, *E. simplicicollis* chose broader and less structurally discrete perches, moved more frequently and over a larger area, and took, on average, much larger prey, although diet overlapped broadly in the two species. *Erythemis* made more frequent feeding flights but with a much lower success rate than *Pachydiplax*; consequently the prey capture rate was similar in the two species. Gut contents of mature, but not of immature, *E. simplicicollis* comprised a significantly greater proportion of body mass than in *P. longipennis*, apparently confirming the importance of larger prey in the diet of the former. (Authors)] Address: May, M.L., Dept Entom., New Jersey Agricultural Experiment Station, Cook College, Rutgers Univ., New Brunswick, NJ 08901-8524, USA. E-mail: may@aesop.rutgers.edu

3013. May, M.L. (2002): Phylogeny and taxonomy of the damselfly genus *Enallagma* and related taxa (Odonata: Zygoptera: Coenagrionidae). *Systematic Entomology* 27: 387-408. (in English). ["The zygopteran genus *Enallagma* has been the subject of numerous behavioural and ecological studies, but phylogenetic relationships among species have been examined only within eastern North America, and even the composition and diagnosis of the genus are unclear on a world-wide basis. Most authorities currently recognize about seventy species within *Enallagma*, comprising two major radiations, in North America and Africa. This study, using morphological data, demonstrates that the North American and a few related Palaearctic species form a monophyletic group that is quite distinct from the African species. The latter are themselves divided into at least three, and probably four, separate clades, one of which may be related to *E. parvum* of India. Consequently, three of Kennedy's long disused genera, *Africallagma*, *Amphiallagma* and *Proischnura* (Kennedy, 1920) are resurrected and two new genera, *Azuragrion* gen.n. and *Pinheyagrion* gen.n. are established for the remaining African taxa. Finally, *Enallagma* is divided into two subgenera, *Enallagma* s.s., the typical 'bluets', including many North American, Holarctic and Palaearctic species, and *Chromatallagma* subgen.n., comprising a group of species of more variable colour that is confined to North America, the Caribbean and northernmost South America." 3018. Monetti, L.; Sanchez-Guillen, R.A.; Cordero Rivera, A. (2002): Hybridization between *Ischnura graellsii* (Vander Linder) and *I. elegans* (Rambur) (Odonata: Coenagrionidae): Are they different species?. *Biological Journal of the Linnean Society* 76(2): 225-235. (in English). ["Two closely related damselflies, *Ischnura graellsii* and *I. elegans*, were analysed for morphological differences and reproductive isolation in the north coast of Galicia (NW Spain). We compared animals from sympatric and allopatric localities, including *I. elegans* from Belgium and *I. graellsii* from southern Spain as pure allopatric populations. A set of morphometric characters were studied by means of multivariate discriminant analysis to determine if these two species can be unambiguously distinguished. Discriminant analysis revealed that *I. graellsii* and *I. elegans* are well differentiated on the first two axis (86% and 11%, respectively). *I. graellsii* individuals are distinguished from *I. elegans* by their smaller size and, specifically, by their narrower and shorter wings and shorter tibiae. In addition, *I. elegans* has a narrower space between the branches of each cercus, and greater distance between the branches of each paraproct. Sympatric individuals are morphologically intermediate, suggesting hybridization. When the species were put together in the laboratory, they showed partial temporal separation in mating behaviour, but males of *I. elegans* readily mated with females of *I. graellsii*, and hybrid individuals were obtained. The opposite heterospecific cross was almost impossible, apparently because of mechanical problems

with the tandem linkage. Laboratory-reared hybrids (from male *I. elegans* X female *I. graellsii*) are morphologically intermediate, mainly resembling the maternal phenotype. Although hybridization between both taxa is common, we suggest maintaining the specific status for both phenotypes because they show incipient reproductive isolation, as it is reported in the literature." (Authors)] Address: Monetti, Liliana, Departamento de Ecología e Biología Animal, Universidade de Vigo, EUET Forestal, Campus Universitario, 36005, Pontevedra, Spain. E-Mail: lmonetti@uvigo.es

3023. Nishu, S. (2002): Discovery of an exceptional habitat of *Libellula angelina* Selys. *Tombo* 44: 31-32. (in Japanese with English summary). [An exceptional habi-

tat of *L. angelina* was found in Kasai City, Hyogo Prefecture, Japan. This endangered species was considered to inhabit typically ponds with sparse vegetation of *Phragmites australis*, *Typha latifolia* and *Zizania latifolia*. 12 exuviae of this species were found on the concrete breast wall of Pond B where *Paspalum distichum* grows sparsely on April 22-IV-2001. On subsequent days until May 13, several males patrolling in their territories and a female ovipositing were observed.] Address: Nishu, S., 247 Gunge Shonomoto, Mikage-cho, Higashinda-ku, Kobe, Hyogo, 658-0057, Japan. E-mail: Snishu@mx2.nisq.net

3024. Novelo-Gutierrez, R.; Gomez-Anaya, J.A.; Arce-Perez, R. (2002): Community structure of Odonata larvae in two streams in Zimapan, Hidalgo, Mexico. *Odonatologica* 31(3): 273-286. (in English). ["Community structure of odonate larvae was investigated at El Saucillo (ES) and San Francisco (SF) streams, from August 1995 to July 1996. Species richness (S), species composition, Margalef's richness index (R), Shannon-Wiener's diversity index (H'), Hill's evenness index (E), and rareness (Rs) were used to describe and compare the communities. Annual variation of the indices was examined within and among streams. Streams were significantly different in terms of physical/chemical variables, and faunistic similarity between the communities was quite low (37%). Mean larval density was highest at ES, but the remaining parameters were highest at SF. Global richness was 31 spp. and some species such as *Hetaerina americana*, *Enallagma civile*, *Anax junius*, *Erpetogomphus elaps*, *Dythemis nigrescens*, *Aeshna multicolor*, *A. dugesi*, *Erythemis plebeja* and the majority of *Argia* spp. were only found at SF. More abundant spp. at SF were *Pseudoleon superbus*, *Telebasis salva*, *Libellula saturata* and *Enallagma praevarum*, while those more abundant at ES were *Paltothemis lineatipes* and *Argia anceps*." 3027. Parr, A. (2002): Lesser Emperor *Anax parthenope* Update. *Atropos* 16: 78. (in English). [Verbatim: "The number of *A. parthenope* seen in Britain since the initial discovery of the species in 1996 now totals at least 45 individuals. Of those dragonflies that were sexed, some 92% have been males with only 8% (3 individuals) being female. Genuine imbalances in the sex ratio of migrating dragonflies have sometimes been noted during periods of visible migration, particularly for darters *Sympetrum* spp., but there are also instances/species where a more equal sex ratio is apparent (Bertram & Haacks 1999, *Libellula* 18: 89-94). The pronounced bias towards records of males in the case of Lesser Emperors seen in Britain must surely in part reflect behavioural differences that make males, especially those holding territory, much more easy to spot than females. One other factor that also needs to be taken into account when considering the British records is the likelihood that females are still being overlooked. Few identification guides as yet contain any illustrations of the female, and with different colour forms existing (Parr 2001) even one picture is not really enough. To facilitate identification of females and to supplement the illustration in Brooks & Lewington (1999) two colour forms are now illustrated on Plate 8 (of *Atropos* 16). It will be of interest to see if more records of females are forthcoming in the next few years, not least in the context of regular breeding in this country."] Address: Parr, A.J., 10 Orchard Way, Barrow, Bury St. Edmunds, Suffolk IP29 5BX, UK

3028. Parr, A. (2002): Migrant and dispersive dragonflies in Britain during 2001. *J. Br. Dragonfly Society* 18(1/2): 40-45. (in English). 3029. Paulson, D.R. (2002): Odonata records from Nayarit and Sinaloa, Mexico, with comments on natural history and biogeography. *Odonatologica* 31(4): 359-370. (in English). ["Although the odonate fauna of the Mexican state of Nayarit has been considered well-known, a 7-day visit there in Sept. 2001 resulted in records of 21 species new for the state, bringing the state total to 120 species, fifth highest in Mexico. Records from a 2-day visit in Aug. 1965 are also listed, many of them the first specific localities published for Nayarit, and the first records of 2 species from Sinaloa are also listed. The biology of most neotropical species is poorly known, so natural-history notes are included for many species. A storm-induced aggregation and a large roost of dragonflies is described. The odonate fauna of Nayarit consists of 2 primary elements: a large number of neotropical species reaching their northern known limits, and a montane fauna of the drier Mexican Plateau. At least 57 species of tropical origin reach their northern distribution in the western Mexican lowlands in or N of Nayarit, and these limits must be more accurately defined to detect the changes in distribution that may be taking place with global climate change."]

3034. Pfau, H.K. (2002): Tandem grip mechanics and tandem linkage shifting in Odonata - reconstruction of evolution and phylogenetic significance. *International Journal of Odonatology* 5(2): 129-179. (in English). ["The functional morphology of the male caudal clasping apparatus of Zygoptera is compared to that of Epiophlebia superstes (Anisozygoptera) and Anisoptera. Hypotheses concerning the mechanics and muscle functions have been advanced by parallel construction of mechanical working models. The evolution of the clasping apparatus and the tandem linkage shifting - from the female pronotum to the head - in the stem group of the Anisozygoptera + Anisoptera (Neoconjuncta) is reconstructed, beginning with a system, which in essential characters resembles that of Epallage fatime (Euphaeidae). New acquisitions of the Neoconjuncta, Anisozygoptera and Anisoptera are described and interpreted. An interdependent evolution of the clasping apparatus + tandem linkage and the flight apparatus is discussed. Characters of both systems in the Euphaeidae and the Neoconjuncta are evaluated as synapomorphies, establishing a group Heteronoda. The Zygoptera are substantiated as a paraphyletic group. The functional morphology of the motion system of the cerial and epiproctal filaments of the Ephemeroptera has been studied for comparison. It shows strongly autapomorphic features, adapted to the display flight." (Author)] Address: Pfau, H.K., Rathenastr. 14, D-65326 Aarbergen, Germany. E-mail: clauspfau@web.de

3045. Relyea, R.A. (2002): Costs of Phenotypic Plasticity. *American Naturalist* 159(3): 272-282. (in English). ["Phenotypically plastic organisms display alternative phenotypes in different environments. It is widely appreciated that possessing alternative phenotypes can affect fitness. However, some investigators have suggested that simply carrying the ability to be plastic could also affect fitness. Evolutionary models suggest that high costs of plasticity could constrain the evolution of optimal phenotypes. However, costs (and limits) of plasticity are primarily hypothetical. Little empirical evidence exists to show that increased plasticity leads to reduced growth and development, leads to increased developmental instability, or limits the ability of organisms to produce more extreme phenotypes. I used half-sib families of larval wood frogs (*Rana sylvatica*) reared in outdoor mesocosms to examine how tadpoles altered behavioral, morphological, and life-historical traits in response to larval dragonfly predators (*Anax longipes*). The predators induced lower activity and the development of relatively large tails and small bodies in wood frogs. As a result, wood frogs experienced reduced growth and development. I then examined whether tadpole sibships with higher plasticity experienced fitness costs (above and beyond the costs of expressing a particular phenotype) and whether they were limited in producing extreme phenotypes. Fitness effects of plasticity were widespread. Depending on the trait examined and the environment experienced, increased plasticity had either positive effects, negative effects, or no effects on tadpole mass, development, and survivorship. I found no relationship between increased plasticity and greater developmental instability. There was also no evidence that sibships with increased plasticity produced less extreme phenotypes; the most extreme trait states were always produced by the most plastic genotypes. This work suggests that costs of plasticity may be pervasive in nature and may substantially impact the evolution of optimal phenotypes in organisms that live in heterogeneous environments." (Author)] Address: Relyea, R.A., Dept Biol. Sciences, University of Pittsburg, Pittsburg, Pennsylvania 15260, USA. E-mail: rarelyea@pitt.edu

3046. Relyea, R.A. (2002): Local population differences in phenotypic plasticity: predator-induced changes in wood frog tadpoles. *Ecological Monographs* 72(1): 77-93. (in English). ["Taxa that are divided into separate populations with low levels of interpopulation dispersal have the potential to evolve genetically based differences in their phenotypes and the plasticity of those phenotypes. These differences can be due to random processes, including genetic drift and founder effects, or they can be the result of different selection pressures among populations. I investigated population-level differences in predator-induced phenotypic plasticity in eight populations of larval wood frogs (*Rana sylvatica*) over a small geographic scale (interpopulation distances of 0.3-8 km). Using a common-garden experiment containing predator and no-predator environments, I found population differences in behavior, morphology, and life history. These responses exhibited a habitat-related pattern: the four populations from closed-canopy ponds did not differ from each other in any of their phenotypes whereas the four populations from open-canopy ponds did differ from each other in these traits. This phenotypic pattern matches the pattern of competitors and predators found in these two types of ponds. Based on two years of pond surveys, the four closed-canopy ponds contained very similar competitor and predator assemblages while the assemblages of the four open-canopy ponds were more diverse and highly variable among open-canopy ponds. When combined with past studies, which demonstrate that predators and competitors select for alternative behavioral and morphological traits, these patterns suggest that the population differences may have arisen via natural selection and not via random mutation or drift. In a second experiment, I cross-transplanted two of the populations into each other's ponds to determine if the populations were locally adapted to the conditions of their native pond (using low and high competition crossed with the presence or absence of a lethal predator). The populations continued to exhibit phenotypic differences, and one of the two populations tested exhibited superior growth in its native pond. This suggests that some wood frog populations are adapted to the local conditions of their natal pond and that localized selection by predation and competition may be the underlying mechanism. Collectively, these experiments indicate that taxa that are divided into discrete populations and face different predator and competitor environments can evolve different phenotypically plastic responses." (Author) Odonate predators were aeshnid and libellulid dragonflies, not further specified.] Address: Relyea, R.A., Dept Biol. Sciences, University of Pittsburg, Pittsburg, Pennsylvania 15260, USA. E-mail: rarelyea@pitt.edu

3047. Relyea, R.A.; Yurewicz, K.L. (2002): Predicting community outcomes from pairwise interactions: integrating density- and trait-mediated effects. *Oecologia* 132: 569-579. (in English). ["[...] many species change their behavior and morphology with different predators and competitors and, thus, change their per-capita interaction rates (i.e. trait-mediated interactions). Our objective was to use a simple experimental community of two predators (larval dragonflies, *Anax longipes*, and larval salamanders, *Ambystoma tigrinum*), two prey (larval green frogs, *Rana clamitans*, and larval bullfrogs, *R. catesbeiana*), and a shared prey resource to determine whether we can predict interactions in a reassembled community by combining our knowledge of density- and trait-mediated interactions. We combined

pairwise laboratory experiments on predation rates and predator-induced behaviors with a mesocosm experiment to examine density- and trait-mediated effects. We used a factorial combination of no predators, caged Anax (to induce anti-predator traits without changing prey density), and lethal Anax crossed with no predators, caged *Ambystoma*, and lethal *Ambystoma*. The species interactions in the reassembled community were qualitatively predictable based on the pairwise experiments. Lethal Anax preyed upon *Ambystoma* and green frogs while lethal *Ambystoma* only preyed upon green frogs. Anax also reduced the activity of the green frogs; this caused a decrease in salamander predation on green frogs, a decrease in green frog acquisition of resources, and an increase in bullfrog acquisition of resources. *Ambystoma* had no effect on green frog activity, no effect on resource acquisition by green frogs, and no effect on resource acquisition by bullfrogs. These results suggest that we can better understand how species interact in natural communities if we have a more detailed understanding of trait-mediated mechanisms. However, if predicting the structure of large communities requires identifying how each species alters its traits in the presence of all other species along with altering density, improving our predictive ability may be a prohibitively large undertaking." 3053. Rudolf, V.; Rödel, M.-O. (2002): Tree-hole breeding frogs in the Upper Guinea rain forest, West Africa. *Verhandlungen der Gesellschaft für Ökologie*, Cottbus 2002: 160. (in English). ["In West African rain forests two tree-hole breeding frogs have been recorded so far: a small ranid, *Phrynobatrachus guineensis* (SVL: 17-22 mm), and a larger hyperoliid species, *Acanthixalus* nov. sp. (SVL: 33-40 mm). *P. guineensis* tadpoles develop in small (2-900 ml) tree-holes and empty snail shells, whereas *A. sp.* selects tree-holes with at least 10 l (up to several hundred l) water volume. *P. guineensis* tadpoles are suspension-feeders and rasps, (20 d from hatching to metamorphosis). *A. sp.* tadpoles are carnivorous (>3 month to metamorphosis). Water filled tree-holes are a limited resource, however holes of intermediate size are not used by any frog for reproduction. Distribution in *P. guineensis* seems to be limited by predation and desiccation risk (selecting tree-holes with water presence at least 20 d, while being eliminated in larger holes that are used by dragonfly larvae). Only the largest tree-holes provide a water persistency period, long enough to assure metamorphosis in *A. sp.* In *P. guineensis* spawning events were clearly positively correlated with time a certain tree-hole is occupied by males. Tadpole densities in this species were extremely high ($x = 0.5$ tadpoles/ml; max: 2 tadpoles/ml). Intraspecific competition significantly negatively affect developmental patterns in *P. guineensis* tadpoles. Neither *P. guineensis*, nor *A. sp.* seems to exhibit any kind of brood-care." 3054. Sahlen, G.; Suhling, F. (2002): Relationships between egg size and clutch size among European species of Sympetrinae (Odonata: Libellulidae). *International Journal of Odonatology* 5(2): 181-191. (in English). ["A negative relationship between clutch size and egg size is generally expected. However, no such trade

off has been reported in Odonata. In this paper we analyse relationships between egg size and clutch size in the dragonfly subfamily of Sympetrinae using material from Norway, Sweden, Germany and France. Clutch size varied within and among the species, and only maximum clutch size was comparable between species. Both egg length and width varied among species. Moreover, mean egg length differed significantly intraspecifically among individual clutches of all species. We found mean egg length to be negatively correlated to clutch size, confirming the trade off between egg size and clutch size across species. Clutch size was positively correlated to female size, but egg size was not." (Authors)] Address: Sahlen, G., Applied Wetland Ecology, School of Business and Engineering, Halmstad University, P. O. 3056. Samways, M.J. (2002): A strategy for the national red-listing of invertebrates based on experiences with Odonata in South Africa. *African Entomology* 10 (1): 43-52. (in English). ["The IUCN Red List of Threatened Species is widely recognized as an authoritative compilation of globally threatened taxa. From an invertebrate perspective it presents a challenging dilemma. As all species are given equal credence, a worm has the same exposure as a whale. Yet there are several million species of invertebrates, thus putting great onus on invertebrate conservationists. South African Odonata species have received considerable conservation focus and have been used to test the most recent IUCN categories and criteria of threat. The importance of overcoming both the taxonomic and perception challenges in invertebrate conservation are discussed. The categorization process is also discussed. Recommendations for South African national red-listing are made, with special reference to the dynamics of such red-listing. A simplified strategy is finally presented, which includes a suggestion for compiling a list of potential focal taxa which in the first instance are not categorized. The species on this list then become a core in field searches, both during wide-scale atlasing and during more focussed threat category assessments." (Author)] Address: Samways M.J., Invertebrate Conservation Research Centre, Dept Zool. & Entomol., University of Na-

tal, P/Bag X01, Scottsville 3209, Pietermaritzburg, South Africa. E-mail: samways@un.ac.za

3057. Schmid-Araya, A.; Hildrew, G.; Robertson, A.; Schmidt, P.E.; Winterbottom, J. (2002): The importance of Meiofauna in food webs: evidence from an acid stream. *Ecology*, 83(5): 1271-1285. (in English). ["Seasonal food webs were constructed for the whole invertebrate assemblage (meio- and macrofauna) inhabiting Broadstone Stream (southeast England). High and uniform taxonomic resolution was applied in a dietary analysis, by resolving the complete benthic community to species, including the meiofauna, protozoa, and algae. Meiofauna accounted for 70% of all species in the summary web and for 73% and 63% of those in the summer/autumn and spring webs, respectively. The web structure changed between summer/autumn and winter/spring, due to differences in species composition. Many stream invertebrates fed on meiofauna and organic matter. Addition of meiofauna to the Broadstone web increased the percentage of intermediate species. Seasonal webs contained between 54 (spring 1997) and 86 (autumn 1996) interactive taxa and 229-378 trophic links. Marked differences in web complexity were found between the summer/autumn and winter/spring periods. Meiofauna accounted for most of the links in the web with a high proportion of intermediate-intermediate links in summer and autumn (0.421-0.440) and also of intermediate-basal links during winter and spring (0.509 0.628). In general, the summary web showed that intermediate species and basal resources were numerically dominant components in this stream. Web connectance rose slightly between summer (0.052) and winter (0.061) and increased further in spring (0.079), coinciding with a reduction in species number. A high fraction of detritivores was combined with omnivorous predators, many of which supplemented their diets with organic matter and, depending on season, with algae and invertebrate eggs. In addition, a wide range of feeding modes was found among meiofaunal species. The diversity of the Broadstone community suggests that the impact of top predators tends to dissipate. A low proportion of top predators in the web was combined with a low mean number of prey items, other than detritus, in their guts (large predators, 1.08-1.26 prey/individual gut; small-sized tanypods, 2.15-2.32 prey/individual gut). Dietary similarity was highest in autumn and winter 1996, and observed feeding links of the most common predatory species showed low overlap in their diets. The web architecture of this stream is reticulate and complex, and the patterns observed in these seasonal webs differed from previous stream webs, resulting in low connectance, high linkage density, long food chains, and a high proportion of intermediate species and of intermediate-intermediate links. The food web derived from Broadstone Stream clearly demonstrates that the meiofauna increases web complexity and thus, taking into account their functional diversity, may be crucial to the understanding of food web properties and ecosystems processes in streams." 3063. Srivastava, D.S.; Melnychuk, M.C. (2002): Ground to canopy distribution of bromeliad-dwelling *Mecistogaster modesta* larvae (Odonata: Pseudostigmatidae) in a Costa Rican rainforest. *IDF-Report* 4(1): 27-30. (in English). ["Larvae of *M. modesta* occur only in bromeliads. We quantified the vertical distribution of larvae in a Costa Rican tropical wet forest, from ground to canopy. Approximately 171 larvae per hectare are estimated to occur in this primary forest, most at intermediate heights above the ground. Only 4% were found in the canopy proper. These distributions reflect mainly spatial patterns in both the size and abundance of bromeliads, although there may also be subtle vertical differences in habitat quality." (Authors) IDF and WdA promoted this study.] Address: Srivastava, D.S., Department of Zoology, University of British Columbia, Vancouver B.C., Canada V6T 1Z4. E-mail: srivast@zoology.ubc.ca

3064. Stange, G.; Stowe, S.; Chahl, J.S.; Massaro, A. (2002): Anisotropic imaging in the dragonfly median ocellus: A matched filter for horizon detection. *Journal of*

Comparative Physiology A-Sensory Neural & Behavioral Physiology 188(6): 455-467. (in English). ["It is suggested that the dragonfly median ocellus is specifically adapted to detect horizontally extended features rather than merely changes in overall intensity. Evidence is presented from the optics, tapetal reflections and retinal ultrastructure. The underfocused ocelli of adult insects are generally incapable of resolving images. However, in the dragonfly median ocellus the geometry of the lens indicates that some image detail is present at the retina in the vertical dimension. Details in the horizontal dimension are blurred by the strongly astigmatic lens. In the excised eye the image of a point source forms a horizontal streak at the level of the retina. Tapetal reflections from the intact eye show that the field of view is not circular as in most other insects but elliptical with the major axis horizontal, and that resolution in the vertical direction is better than in the horizontal. Measurements of tapetal reflections in locust ocelli confirm their visual fields are wide and circular and their optics strongly underfocused. The ultrastructure suggests adaptation for resolution, sensitivity and a high metabolic rate, with long, widely separated rhabdoms, retinulae cupped by reflecting pigment, abundant tracheoles and mitochondria, and convoluted, amplified retinula cell plasma membranes." Box 475, Canberra, ACT, 0200, Australia. E-Mail: gert.stange@anu.edu.au

3065. Stavenga, D.G. (2002): Colour in the eyes of insects. *Journal of Comparative Physiology A-Sensory Neural & Behavioral Physiology* 188(5): 337-348. (in English). ["Many insect species have darkly coloured eyes, but distinct colours or patterns are frequently featured. A number of exemplary cases of flies and butterflies are discussed to illustrate our present knowledge of the physical basis of eye colours, their functional background, and the implications for insect colour vision. The screening pigments in the pigment cells commonly determine the eye colour. The red screening pigments of fly eyes and the dorsal eye regions of dragonflies allow stray light to photochemically restore photoconverted visual pigments. A similar role is played by yellow pigment granules inside the photoreceptor cells which function as a light-controlling pupil. Most insect eyes contain black screening pigments which prevent stray light to produce background noise in the photoreceptors. The eyes of tabanid flies are marked by strong metallic colours, due to multilayers in the corneal facet lenses. The corneal multilayers in the gold-green eyes of the deer fly *Chrysops relictus* reduce the lens transmission in the orange-green, thus narrowing the sensitivity spectrum of photoreceptors having a green absorbing rhodopsin. The tapetum in the eyes of butterflies probably enhances the spectral sensitivity of proximal long-wavelength photoreceptors. Pigment granules lining the rhabdom fine-tune the sensitivity spectra." 3066. Steglich, R.; Müller, J. (2002): Eine wertvolle kleine Libellen-Sammlung (Odonata) aus den Jahren 1923 bis 1944 im Heimatnaturgarten Weißenfels (Coll. Beuthan). *Entomol. Mitt. Sachsen-Anhalt* 9(2): 37-41. (in German). [The collection of Odonata included some

very remarkable species from Sachsen-Anhalt, Germany. *Nehalennia speciosa* is new for this Federal State, some more species are interesting indicators to assess and to date the impact of water pollution on odonate assemblages (*Gomphus vulgatissimus*). The importance of this collection which covers a period with very few information on the German odonate fauna is outlined. Of special interest are records of *Coenagrion mercuriale* and *Epiteca bimaculata*.] Address: Steglich, Rosmarie, Quittenweg 53, 39118 Magdeburg, Germany

3067. Taketo, A. (2002): Notes on recent information of odonate fauna in Ishikawa and Fukui Prefectures, Honshu. Tombo 44: 29-30. (in Japanese with English summary). [Information on 13 species are given. In the English summary an record of *Sympetrum cordulegaster* (teneral male early in July), a teneral female of *Pantala flavescens* (late in October, 2001), and a population, counting 300 individuals, of *Gomphus postocularis* in a concrete ditch running through the streets of Fukui City are high lighted.] Address: Taketo, A., 1-19, Ishibiki 1-chome, Kanazawa City, 920, Japan

3068. Tarr, T.L.; Babbitt, K.J. (2002): Effects of habitat complexity and predator identity on predation of *Rana clamitans* larvae. *Amphibia-Reptilia* 23(1): 13-20. (in English). ["We examined the microhabitat distribution of green frog larvae (*Rana clamitans*) and two common predacious insect genera at 27 wetlands in southern New Hampshire to determine if it was related to the presence of vegetation. *Rana clamitans* and hemipterans (*Belostoma* spp.) were rarely captured in non-vegetated microhabitats. Larval odonates (*Aeshna* spp.) were captured more frequently in vegetated microhabitats but the difference was not significant. In a laboratory experiment, we tested the effects of plant density on the survival of *R. clamitans* larvae exposed to either *Belostoma flumineum* or *Aeshna mutata*. When no cover was available, survival of *R. clamitans* tadpoles was very low when exposed to either predator. *Belostoma flumineum* was a less effective predator than *A. mutata*, and survival rates of tadpoles did not differ between high and low plant density when exposed to this predator. In contrast, survival of tadpoles was significantly higher in the high density vegetation treatment compared to the low density treatment when exposed to *A. mutata*. Although plant structure can reduce predation on *R. clamitans* larvae, the level of structure necessary to significantly mediate predation may depend largely on the foraging mode of the predator." (Authors)] Address: Tarr, Tracy L., Department of Natural Resources, University of New Hampshire, Durham, NH, 03824, USA. E-Mail: kbabbitt@christa.unh.edu

3069. Theischinger, G. (2002): Preliminary keys for the identification of larvae of the Australian Petaluridae, Archipetalidae, Austropetalidae, Telephlebiidae & Aeshnidae (Odonata). The Murray-Darling Freshwater Research Center. Identification & Ecology Guide No. 42: I-IV, 102 pp. (in English). [The Petaluridae, Archipetalidae, Austropetalidae, Telephlebiidae and Aeshnidae represent 56 of the recognised Australian species in 18 genera. "It is the aim of this presentation to facilitate the identification of all known larvae of several groups of Australian dragonflies whose identification up to now would have required a rather large number of papers, some of them containing misleading errors. There is also strong emphasis on the still existing gaps in our knowledge. To establish and confirm family iden-

tification, an updated version of the family key presented by Hawking & Theischinger (1999) is given at the beginning. In addition there are, for each of the five families concerned, a taxonomic overview, a brief diagnosis and when appropriate a key to genera and species followed by more detailed generic and specific treatments. Whereas the genus lists given for each family and the species lists given for each genus are alphabetical, the more detailed treatments of genera and species are arranged in an order of detected similarity which may or may not reflect phylogenetic relationships." Taxonomic notes and diagnoses under higher taxa only cover the Australian members. "Measurements and descriptions are given from last instar larvae (L) or from final instar exuviae (E). Most illustrations are given from final instar exuviae. As colouration of individuals may be variable in life due to specific conditions in the habitat and as colouration of preserved specimens may reflect the ways or methods of collection and preservation, colours are not given in the descriptions [...]. Generally pubescence is rather weak in all taxa and does not appear particularly useful for diagnoses. It is omitted in illustrations of most larvae or exuviae but presented and specified in some detail illustrations and descriptions. Smoothness or dentation of labial palps may to some degree be effected by conditions of habitat and food and possibly others. Generally only the most reliable characters are used in keys and diagnoses. In spite of that the keys may be of limited use for identifying specimens other than final instar larvae and exuviae. All diagnoses are made up in the same style facilitating comparison with taxa of the same rank and confirmation of the results obtained from running the keys." In addition, colour pictures of the following species (larvae or imagos) are presented: *Austropetalia tonynana*, *Hemianax papuensis*, *Petalura ingentissima*, *Austroaeschna flavomaculata*, *Archipetalia auriculata*, *Antipodophlebia asthenes*, *Telephlebia godeffroyi*, *Austroaeschna atrata*, *Austroaeschna inermis*, *Dendroaeschna conspersa*, *Petalura gigantea*, *Austropetalia patricia*, *Acanthaeschna victoria*, *Austroaeschna unicornis*, and *Anax guttatus*.] Address: Murray Darling Freshwater Research Centre, P.O. Box 921, Albury, 2640, Australia

3070. Theischinger, G.; Brown, G.R. (2002): The larva of *Huonia melvillensis* Brown & Theischinger (Anisoptera: Libellulidae). *Odonatologica* 31(3): 319-322. (in English). [The larva of *H. melvillensis* - the species is known only from Melville Island, off the northern coast of Australia - is described from 5 final instar exuviae from the type locality.] Address: Theischinger G., 2A Hammerley Road, Grays Point, NSW 2232, Australia

3071. Thomas, B. (2002): Temperaturrekorde in den 1990er Jahren und früher Beginn von Flugzeit und Fortpflanzung bei häufigen Libellenarten in Nordwestdeutschland (Odonata). *Libellula* 21(1/2): 25-35. (in German, with English summary). ["As another fingerprint of climate change, data on the flying season of dragonflies are related to the average air temperatures. In the district of Viersen, Northrhine-Westphalia, Germany, the temperature from March to August rose from 13,1 °C in 1951-1980 to 14,4 °C in 1990-1999. The dragonfly data compared here were collected during the 1980s and 1990s. On the average, in the 17 most widespread species the earliest records of flight and reproduction dated nearly two weeks earlier in the 1990s. The shift was stronger and more frequent in species

with an early starting flying season: the reproductive periods of *Pyrrhosoma nymphula*, *Coenagrion puella*, *Ischnura elegans*, *Libellula depressa*, and *L. quadrimaculata* started 20-28 days earlier than in the 1980s. From September onward there were no obvious trends, regarding neither the average air-temperatures nor shifts of the flying seasons." (Author)] Address: Thomas, Barbara, Biologische Station Krickenbecker Seen e.V., Krickenbecker Allee 17, D-41334 Nettetal, Germany. E-mail: barbara-thomas@web.de

3072. Thompson, D.J.; Fincke, O.M. (2002): Body size and fitness in Odonata, stabilising selection and a meta-analysis too far?. *Ecological Entomology* 27(3): 378-384. (in English). [Sokolovska et al. (2000) (see OAS 1947) concluded that "there is a general fitness benefit to large size in odonates". In this paper, Thompson & Fincke critically re-analyze the meta- data and conclusions. They conclude that of the eight species for which studies provide comparable data on lifetime mating success, only five reported statistics for both longevity and mating rates, the two major fitness components comprising lifetime mating success. Hence, only five of the species listed in table A1 (Sokolovska et al., 2000) could be used correctly to address the question of possible trade-offs between longevity and mating rate with respect to size [...]. Given the multiple weaknesses of the analysis, the conclusion of Sokolovska et al. (2000) that 'large size is associated with increased lifetime reproductive success in odonates of both sexes' is at best overstated and at worst misleading. Indeed, as a taxon, the Odonata seem to be an exception to any trend for selection on large size; the advantage of small size for aerial manoeuvrability probably counters any large size advantage in many species (Fincke et al., 1997). Future meta-analyses may be used fruitfully to determine trends with respect to selection for size and phylogeny, mating systems, or the degree and direction of sexual size dimorphism, however the application of the technique demands a knowledgeable and critical reading of the studies in the literature. It remains unclear whether even a meta-analysis can handle the dual possibility of stabilising and directional selection acting within a taxon. Finally, lifetime mating success should not be equated with lifetime reproductive success. The latter usually refers to the number of eggs fertilised by males or laid by females. The use of either measure as a fitness correlate remains untested for most species. For *Megaloprepus coerulatus*, a highly territorial species in which males are under strong sexual selection on body size, neither male fertilisation success nor female clutch size was a good predictor of realised fitness among mated individuals (Fincke & Hadrys, 2001). In both sexes, larval ecology constrains selection on adult size. Future studies designed to identify contrasting selective pressures acting on body size in insects at both the adult and immature stages of their life history are critical to clarify the true picture of how body size affects fitness in organisms with a complex life cycle. As pointed out by Sokolovska et al. (2000), far more emphasis is needed on the larval stage of most odonates. After all, any selection on adult size of odonates begins when they are still in the water." [IDF helped Otto Mesumbe (Cameroon Dragonfly Project; CDP) to study the Odonata of the Takamanda-Mawne Forest Reserves, a region likely to be one of the highest importance for odonate diversity in Africa. The results of this excursion, and two additional collections are listed and crossreferenced with locality data. In addition some interesting information are given on the CDP, Cameroon as a hot spot region for dragonfly diversity in Africa, relict elements in the fauna, and African Calopterygidae.] Address: Vick G.S., Crossfields, Little London, Tadley, Hants RG26 5ET, UK

3077. Viessmann, R. (2002): Libellen - Odonata. Pflanzen und Tiere in Rheinland-Pfalz - Berichtsjahr 2001 - Heft 12: 179-191. (in German). [Compilation of dragonfly records from different habitats situated in Rheinland-Pfalz, Germany. Of faunistic interest are the records of *Coenagrion mercuriale*, *Erythromma najas*, *Ischnura pumilio*, *Lestes barbarus*, *L. virens*, *Sympetma fusca*, *Aeshna affinis*, *Anax parthenope*, *Onychogomphus forcipatus*, *Ophiogomphus cecilia*, *Thecagaster bidentata*, *Crocothemis erythraea*, *Libellula fulva*, and *Orthetrum brunneum*.] Address: Viessmann, R., Gängelstockweg 8, D-67295 Bolanden, Germany

3078. Vorndran, I.C.; Reichwaldt, E; Nürnberger, B. (2002): Does differential susceptibility to predation in tadpoles stabilize the *Bombina* hybrid zone?. *Ecology* 83(6): 1648-1659. (in English). ["Despite substantial divergence, the European toads *Bombina bombina* and *Bombina variegata* (*Anura*: *Discoglossidae*) interbreed freely wherever their parapatric distributions adjoin. Natural selection that stabilizes the resulting hybrid zones should rest in part on the adaptation to different breeding habitat of the pure taxa. While *B. bombina* lays its eggs in semipermanent ponds, *B. variegata* is a typical puddle breeder. Here, we investigate whether selection for rapid larval development in *B. variegata* has resulted in the loss of effective antipredator defenses, thus exc-

cluding this species from predator-rich ponds. We collected adults from four populations in Romania (two for each taxon) and reared the offspring from four crosses per population in the laboratory either in the presence or in the absence of caged odonate predators (*Aeshna cyanea*). In predation trials, we found no taxon difference in mortality rate among tadpoles that had been reared with predators. The resilience of *B. variegata* tadpoles may have been due to their remarkable phenotypic plasticity. In both taxa, predator presence led to the development of a higher tail fin, which has been shown to reduce predation rates in other amphibians. This response was much stronger in *B. variegata* than in *B. bombina*. Moreover, differences between the two *B. variegata* populations in terms of laboratory predation rates and levels of plasticity correlated with predator abundance at the collection sites so as to suggest local adaptation in predator defenses. Finally, delayed metamorphosis in the predator-induced morphs of both taxa implies a cost to the defense. Given the heterogeneity of temporary habitat in terms of desiccation rate and predator occurrence, the greater amount of phenotypic plasticity in *B. variegata* fits predictions of life history theory. At the same time, our results leave the question unresolved as to why this species avoids ponds." Inst. für Ökologie und Parasitologie, Universität Karlsruhe: 132 pp. (in German). [On a broad ecological basis, bio-ecological and hydrochemical factors of 19 water bodies in the Bienwald-region (Rheinland-Pfalz, Germany) were sampled. The study aims to get information on the development of these water bodies in the framework of their function as food habitats of the White Stork (*Ciconia ciconia*), a species once extinct but now re-established. Heteroptera, water-Coleoptera, molluscs, amphibians, and Odonata were surveyed. A total of 22 odonate species was collected including species of thermic preferred waters as *Lestes barbarus* and Cro-

preferred waters as *Lestes barbarus* and *Crocothemis erythraea*, or rare species as *Brachytron pratensis*.] Address: Werth, Christine, Mittelberg 4, D-76571 Gaggenau, Germany

3082. Westermann, K.; Westermann, E. (2002): Das Große Granatauge (*Erythromma najas*) am Schlüchtsee - erster Bodenständigkeitsnachweis für den Schwarzwald. *Naturschutz südl. Oberrhein* 3: 189-192. (in German, with English summary). [At lake Schlüchtsee (County of Waldshut, southeastern Black Forest, Baden-Württemberg, Germany), 914 m a.s.l., a large population of *E. najas* was found. This first proof of reproduction obtained for the Black Forest is likewise the highest altitude record in Baden-Württemberg and Germany.] Address: Westermann, K., Buchenweg 2, D-79365 Rheinhausen, Germany. E-mail: fosor@t-online.de

3083. Westermann, K. (2002): Phänologie der Emergenz bei der Gemeinen Weidenjungfer (*Chalcolestes viridis*) an südbadischen Altrheinen. *Naturschutz südl. Oberrhein* 3: 201-214. (in German, with English summary). [A systematic sampling of exuviae near the town of Weisweil (County of Emmendingen, Federal state of Baden-Württemberg, Germany) totalled in app. 38 000 exuviae of *C. viridis*. "The earliest start of emergence was noticed on 23 June 1998. Along one section with a very high abundance of emerging and adult imagines, emergence always started only in late July. At this site emergence finished in four years around 20 September. In 1999, a year of high floods, imagines emerged regularly also along other sections until mid September. The median of different sections varied, in the extremes it dated before mid July and on 31 August. Within 800 m linear distance between sections the median shifted significantly according to lower water temperature in two years of the study towards later dates. The duration of the emergence is described by two variables. The peak of emergence is defined as the interval between the first and third quartile, the main periods of emergence as the interval between the dates when 10% and 90% of all imagines emerged, respectively. In this study the two variables reached average values of 12 and 22 days respectively in 17 samples. Within all samples the number of emerged imagines can be described by the logistic model of growth. Median, peak of emergence and main period of emergence are the more useful variables to describe the emergence, rather than the frequently used EM50 - Index. In the early period of emergence a higher proportion of females emerge, in total more males emerged." (Author)] Address: Westermann, K., Buchenweg 2, D-79365 Rheinhausen, Germany. E-mail: fosor@t-online.de

3084. Wichard, W.; Arens, W.; Eisenbeis, G. (2002): Biological atlas of aquatic insects. Edition 1. Apollo-Books, Stenstrup. ISBN 87-88757-60-9: i-iv; 339 pp. (in English). [This atlas gives an overview of the numerous adaptations of aquatic insects in an aquatic environment. 12 orders of aquatic insects are covered including Odonata (chap. 2.3, pp. 38-61). Bibliographical references, an index of scientific names, and a subject index are included. It was written for graduate students and research professionals in the field. 148 picture plates are included as well as 150 line drawings, graphs and diagrams. These SEM photographs give a fascinating insight into a lot of morphological structures of larval Odonata including e.g. an emerging prolarva of a Sym-

petrum sp.] Address: Apollo books, Kirkeby Sand 19, DK-5771 Stenstrup, Denmark. W-mail: apollobooks@vip.cybercity.dk

3085. Wildermuth, H. (2002): Artenschutz im Spannungsfeld zwischen Forschung und Umsetzung - Beispiel Libellen (Odonata). Artenschutzreport 12: 1-6. (in German with english summary). ["Conservation of animal species requires interaction between applied research and realisation of projects. This is exemplified by the dragonflies (Odonata), an insect order that is represented by about 80 species in Central Europe. Research related to dragonfly conservation comprises quantified ecofaunistic surveys with evidence of autochthony, ecological analyses of limiting niche factors, mainly of larvae, ecophysiological studies of habitat recognition by adults and investigations of habitat use as well as population biology and dispersal. Thereby, research concentrates on threatened species. The realisation of conservation projects is based on the results of research aimed at single species or species communities. Preservation of primary biotopes, especially of rare larval habitats, must obtain priority. Secondary biotopes such as water bodies in partly drained moorland, gravel excavations or man-made ponds may also be of some importance for numerous species. However, most of them need continuous management or regeneration. The rotary management of small ponds enables the establishment of a mosaic of all succession stages, which changes in space and time on a confined area, thus providing permanent habitats for a high diversity of aquatic organisms. Success in species preservation ultimately depends less on research than more on the good will of all the people concerned and on the high qualities of the conservancy actors." (Author)] Address: Wildermuth, H., Haltbergstr. 43, CH-8630 Rüti, Switzerland. E-mail: hansruedi@wildermuth.ch

3086. Wildermuth, H. (2002): Kadaver von Somatochlora flavomaculata als Rendezvous-Platz für Skorpionfliegen (Mecoptera: Panorpidae; Odonata: Corduliidae). Libellula 21(1/2): 65-69. (in German, with English summary). ["A pair of *S. flavomaculata* was found dead in an orb-web of *Larinioides cornutus* suspended above a pond. The carcasses were obviously not, or not completely, eaten by the spider and therefore attracted some flies and scorpionflies (*Panorpa communis*). Up to five *Panorpa* individuals comprising both sexes assembled simultaneously on the carcasses. The dragonflies were probably trapped shortly after the male had grasped the female in flight for copulation above the oviposition site and served subsequently as rendezvous for scorpionflies."(Author)] Address: Wildermuth, H., Haltbergstr. 43, CH-8630 Rüti, Switzerland. 3087. Wildermuth, H.; Knaus, P. (2002): The impact of incidental summer snowfall on two alpine metapopulations of *Somatochlora alpestris* (Selys) (Anisoptera: Corduliidae). Odonatologica 31(1): 55-63. (in English). ["In the course of a 2-yr mark-resighting study on *S. alpestris* at 2000 m a.s.l. in the Central Alps of Switzerland snow fell during the beginning of the reproductive period in July 2000. The snow cover was up to 30 cm thick and remained for about 8 days. Only 3% of the individuals marked as teneral and 4% of those marked as matures before the cold spell were resighted afterwards. In 1998 (a season without snow) the corresponding resighting proportions amounted 10% and 54%

respectively. In 2000, at a second study site at 1700-1800 m, 11 % of the individuals marked as matures before the cold spell were found again. It is concluded that, unlike the aquatic stages, the imagines of *S. alpestris* are not well adapted to survive cold periods with snowfall lasting more than a few days. Various survival strategies focused on egg and larval development of the sp. are discussed with respect to adaptation to a subarctic climate." (Authors)] Address: Wildermuth, H., Haltbergstr. 43, CH-8630 Rüti, Switzerland. E-mail: hansruedi@wildermuth.ch

3088. Yokoi, N.; Mitamura, T. (2002): Description of a new *Macromia* species from Central Laos (Odonata: Corduliidae). Tombo 44 : 9-10. (in English with Japanese summary). [*M. vangviengensis* sp. n. is described from central Laos. The new species is characterized (differentiated from species of the *M. clio*-group) by its smaller size, developed triangular projection on the 10 th abdominal segment and the absence of the antehumeral band. Holotype : Male, Ban Phon-Ngam (18° 55' N, 102° 27' E), Vangvieng, central Laos, 28-VI-1994, T. Mitamura leg. The specimen will be deposited in the Swedish Museum of Natural History.] Address: Yokoi, N., 2-37-11 Kaisei, Koriyama, Fukushima, 963-8851 Japan; Mitamura, T., 3-20 Youkodai, Yanagawa, Fukushima, 960-0760 Japan

3089. Yokoyama, T. (2002): A record of *Aeschnophlebia longistigma* from Tobetsu-cho. Bulletin of The Hokkaido Odonatological Society 14: 11. (in Japanese). [A female was caught at 13 July, 2001.] Address: Yokoyama, T., 1-15-303, Higashi 22chome, Kita 19jo, Higashi-ku, Sapporo City, 065, Japan

3090. Yokoyama, T. (2002): Discovery of *Aeshna mixta* soneharai Asahina in Tokachi subprefecture, Hokkaido. Tombo 44: 34. (in Japanese with English summary). [The northern limit of the range of *A. mixta* sonehara in Japan is Asashikawa-shi, Hokkaido (Anzai, 1997), while the eastern limit was considered in the Hidaka Province, Hokkaido (Fukumoto, 1987; Itoh, 1993). In 2001, the author confirmed the species in the Tokachi Province, which turns out to be the new most eastern distributional record in this species in Japan.] Address: Yokoyama, T., 1-15-303, Higashi 22chome, Kita 19jo, Higashi-ku, Sapporo City, 065, Japan

3091. Yokoyama, T. (2002): Larval duration of *Somatochlora uchidai* Foerster. Bulletin of The Hokkaido Odonatological Society 14: 5-10. (in Japanese). [The life history of *S. uchidai* is documented in considerable detail in different tabs.] Address: Yokoyama, T., 1-15-303, Higashi 22chome, Kita 19jo, Higashi-ku, Sapporo City, 065, Japan

3092. Young, M.E. (2002): Dragonflies: they're ravenous, a little scary and oh-so-helpful: Bugs have an appetite for pests and no real drawbacks, experts say. The Dallas Morning News 21 July 2002: (in English). [This is a popular account on Odonata in a newspaper; the article is documented in *Argia* 14(3): 21-22] Address: myoung@dallasnews.com

Thanks to all who contributed to this issue of OAS!
A special thank to Viola Clausnitzer for linguistic help.

- 3093.** Carletti, B.; Terzani, F. (1997): Descrizione di *Pseudagrion simplicilaminatum* spec. nov. sulla Repubblica del Congo (Odonata: Coenagrionidae). *Opusc. zool. flum.* 152: 1-7. (Italian with English summary). ["The new species is described and illustrated, and its affinities with *P. flavipes leonensis* Pinhey, 1964 and *P. thenartum* Fraser, 1955 are outlined and discussed. Holotype ♂: Kintele, 6-IX-1978, paratypes ♂: Kintele, 5-I-1980, II-1980, III-1980, XII-1980; — Voka, I-1980; — Djili, XII-1979; — Loufoula, I-1980." (Authors)] Address: Carletti, B., Viale Raffaello Sanzio 5, I-50124 Firenze, Italy
- 3094.** Fujimoto, K. (1997): New Record of *Neurothemis* from Inomote Island of the Ryukyus. *Aeschna* 33: 27-28. (in Japanese with English summary). [*Neurothemis* sp. and *Rhyothemis phyllis* are documented along with weather maps.] Address: not stated in English
- 3095.** Katatani, N.; Muraki, A. (1997): Records of the Odonata taken in Palau, Part I. *Aeschna* 33: 1-10. (in Japanese with English summary). [5 species were collected from 27 Feb. to 1 March 1996 on Palau (Carolinean Islands, SE of the Philippines). *Agriocnemis femina* (Brauer 1868), *Ischnura senegalensis* (Rambur 1842), *Teinobasis palauensis* Lieftinck 1962, and *Hemicordulia lulico* Asahina 1940 were illustrated. The latter is compared with *Hemicordulia mindana* Needham & Gyger 1937 from the Ryukyus. *I. senegalensis* was detected for the first time on Palau, and the previously unknown ♀ of *T. palauensis* is illustrated and described for the first time.] Address: Muraki, A., Shigino-nishi 3-4-2-309, Jôtô-ku, Osaka C., Osaka 536, Japan
- 3096.** Kitagawa, K. (1997): Records of the Odonata from Penang Island, Malaysia. *Aeschna* 33: 11-18. (in Japanese with English summary). [32 species were taken in 1995 and 1996, of which 17 species are new records from Penang Island. These records total the known species to 54. *Prodasineura collaris* (Selys 1860), *P. notostigma* (Selys, 1860), *Calicnemia chaseni* (Laidlaw 1928), *Microgomphus chelifera* Selys 1858, and *Orchithemis pulcherrima* Brauer, 1878 are documented by back and white photos, and in the case of *Prodasineura* species with drawings of the synthorax.] Address: Kitagawa, K., Imaiti 1-11-6, Asahi-ku, Osaka C., Osaka, 535-0011, Japan
- 3097.** Kitagawa, K. (1997): Records of the Odonata from Sarawak, Malaysia]. *Aeschna* 34: 5-10. (in Japanese with English summary). [In Dec. 1990, 27 odonate species from Kuching were brought on record. Drawings illustrate the labrum of ♀ *Vestalis amaryllis* and *V. atropa*. Black and white photos refer to *Prodasineura dorsalis*, *Amphicnemis wallacei*, *Coeliccia coomansi*, *Indaeschna grubaueri*, *Brachygonia oculata*, and *Euphaea* sp.] Address: Kitagawa, K., Imaiti 1-11-6, Asahi-ku, Osaka C., Osaka, 535-0011, Japan
- 3098.** Kitagawa, K.; Sugitani, A.; Hayashi, K.; Masaki, N.; Muraki, A.; Katatani, N. (1997): Records of the Odonata of Hong Kong, Part IV. *Aeschna* 34: 11-21. (in Japanese with English summary). [In June, July, and Oct. 1996, a total of 69 species was recorded, of which *Cercion sexlineatum* is a new addition to the Hong Kong odonate fauna.] Address: Kitagawa, K., Imaiti 1-11-6, Asahi-ku, Osaka C., Osaka, 535-0011, Japan
- 3099.** Kohama, T. (1997): Odonata from Kohama Island, the Ryukyus. *Aeschna* 33: 19-20. (in Japanese with English summary). [On 20 Sept., 1985, 8 odonate species - in total new to the Island - were recorded.] Address: not stated in English
- 3100.** Kohama, T. (1997): Odonata from Shimoji Island of Aragusuku Islands, the Ryukyus. *Aeschna* 33: 21-22. (in Japanese with English summary). [On 18 July, 1985, 6 odonate species were recorded.] Address: not stated in English
- 3101.** Moriyasu, A. (1997): A record of the larvae of *Macromia daimoji* OKUMURA from Shikoku, Japan. *Aeschna* 34: 36. (in Japanese). [29-XII-1996; documentation of the habitat.] Address: not stated in English
- 3102.** Moriyasu, T. (1997): Larval development of *Macromia daimoji* OKUMURA in nature. *Aeschna* 33: 31-36. (in Japanese with English summary). [Kurashiki-city, Okayama Pref., Japan; the study documents extensively the larval growth of *M. daimoji*; larval development lasts 2 years including 9 instars.] Address: not stated in English
- 3103.** Naraoka, H. (1997): A list of dragonflies in Hotokeuma marsh, Aomori Prefecture (Insecta, Odonata). *The Journal of The Natural History of Aomori* 2: 19-21. (in English translation of Naoya Ishizawa in *Digest of Japanese Odonatological Short Communications* 8, 1998). [The history of a water body near Misawa City, Japan is briefly outlined along with a list of 34 odonate species recorded.] Address: Naraoka, H., 36-71, Motoizumi, Fukunoda, Itayanagi-cho, Kita-gun, Aomori Prefecture, 038-3661, Japan

3104. Schmidl, J. (1997): Adephege Wasserkäfer in schwäbischen Niedermooren - Faunistische Ergebnisse von Aufsammlungen in Kleingewässer-Neuanlagen der Natur- und Artenschutzprogramme. (Coleoptera: Halipilidae, Noteridae, Dytiscidae, Gyrinidae). Ber. naturforsch. Gesell. Augsburg 56: 6-17. (in German, with English summary). [Bayern, Germany; *Sympecma fusca*, *Brachytron pratense*, *Aeshna grandis*, *A. juncea*, *Somatochlora flavomaculata*, and *Sympetrum striolatum* are listed from different localities in Sept. 1995.] Address: Schmidl, J., Lettenstr. 8, D-90562 Kalchreuth, Germany

3105. Sugimura, M. (1997): Migrant species of the Odonata into Kochi Prefecture recorded in the first half of the 1990's. *Aeschna* 33: 23-25. (in Japanese with English summary). [*Anaciaeschna jaspidea*, *Anax guttatus*, *Brachydiplax chalybea*, *Sympetrum cordulegaster*, *S. fonscolombii*, *Hydrobasileus croceus*, and *Tholymis tillarga* are treated.] Address: Sugimura, M., 9-7, Uyamasatsuki-cho, Nakamura City, Kochi Prefecture, 787, Japan

3106. Tabata, O. (1997): New Record of *Zyxomma obtusum* SELYS from Inomote Island of the Ryukyus. *Aeschna* 33: 29-30. (in Japanese with English summary). [*Z. obtusum* was recorded at three dates in 1996.] Address: Tabata, O., Shoubuen-cho 79-18, Kamigamo, Kita-ku, Kyoto C., Kyoto 603-8064, Japan

3107. Tone, S.; Yagi, T. (1997): Records of the exceptional migration of *Anax guttatus* (Burmeister) and *Tramea virginia* (Rambur) out of seasons in 1994 at Mie Prefecture, central Japan. *Aeschna* 34: 29. (in Japanese with English summary). [This is a detailed account on migrating *A. guttatus* and *T. virginia* in dependence of weather conditions.] Address: Yagi, T., Otobe 2113-102, Tsu C., Mie 514-0016, Japan

3108. Yoshida, M. (1997): A study on the migration of Odonata for extending their habitats. *Aeschna* 33: (in Japanese with English summary). [Japan; the paper compiles the ability of different odonate species to colonise new water bodies from published studies.] Address: not stated in English

1998

3109. Bernabei, S.; Di Girolamo, I.; Iavarone, I. (1998): Alcune note sul popolamento macrobentonico del fiume Arone (Lazio, Italia). *Riv. Idrobiol.* 37: 203-209. (in Italian with English summary). [The checklist of macrozoobenthos of the River Arrone, Italy includes 11 species of Odonata. Of interest are *Pyrrhosoma nymphula* and *Onychogomphus uncutus*. No additional odonatological details are given.] Address: Bernabei, S., Istituto Superiore di Sanita, Laboratorio di Igiene Ambientale, Viale Regina Elena 299, I-00191 Roma, Italy

3110. Cordero Rivera, A.; Pérez, F.J.E. (1998): Mating frequency, population density and ♀ polychromatism in the damselfly *Ischnura graellsii*: an analysis of four natural populations. *Etologia* 6: 61-67. (in English with Spain summary). ["The maintenance of ♀ polychromatism in *I. graellsii* is addressed by reanalysing data from two natural populations studied by Cordero (1992, *J. Anim. Ecol.*, 61:769-780) and two additional populati-

ons. We used mark-resighting methods to estimate mating frequency by ♀ morphs. Results indicate that ♀ mating probability is positively related to ♂ density in three populations, but androchrome (♂-like ♀♀) only mated less often than gynochromes in one sample. ♀ morphs did not differ in size and oviposition frequency. Nevertheless, among populations, androchrome frequency was positively related to an index of ♂ density. We suggest that population density might have an effect on the maintenance of ♀ morphs in *I. graellsii*, but this does not seem to be because androchrome ♀♀ avoid matings. A more accurate analysis of the benefits and costs of mating in polychromatic damselflies is needed." (Authors)] Address: Cordero Rivera, A., Departamento de Ecología e Biología Animal, Universidad de Vigo, E.U.E.T. Forestal, Campus Universitario, 36005 Pontevedra, Spain. E-mail: acordero@uvigo.es

3111. Deliry, C. (1998): Nouveaux articles ou études concernant les libellules dans la région Rhône-Alpes. *Sympetrum piémontais* 38: 2-3. (in French). [France; regional odonatological bibliography covering the period 1996/98 and abstracting in most cases unpublished expertises.] Address: Deliry, C., La Paluette, 2338 route de Belley, F-38490 Aoste, France

3112. Glotzhober, R. (1998): Tiger seen in Ohio's Hill Country. *WildOhio*. Spring 1998. *WildOhio* (Ohio Division of Wildlife newsletter) Spring 1998: 17. (in English). [Ohio, USA; *Cordulegaster erronea*] Address: Glotzhober, R., Ohio Natural history society, 1982 Velma Ave., Columbus OH 43211-2497, USA. E-mail: bglotzhober@ohiohistory.org

3113. Naraoka, H. (1998): Establishment of *Pseudothemis zonata* to central and south of Aomori. *Gekkan-Mushi* 342: 45- (in Japanese). [5. July 1998; published records from Aomori Pref., Japan are compiled, and the current range extension is discussed with special emphasis to global warming. A translation of the paper is published in *Digest of Japanese Odonatological Short Communications* 14] Address: Naraoka, H., 36-71, Motoizumi, Fukunoda, Itayanagi-cho, Kitatsuguru-gun, Aomori Prefecture, 038-3661, Japan

3114. Taketo, A. (1998): On the Odonate fauna of Ishikawa and Fukui Prefectures in 1998. *Tombo* 41: 33-36. (in Japanese with English summary). [Two adult ♂♂ of *Trigomphus ogumai* were captured at Daishoji, Ishikawa Pref., Japan at its northern range limit on the Japan Sea side. New locality records of rare species, include *Sympecma p. paedisca* (a coastal pond at Hakui / Ishikawa), *Nihonogomphus viridis* (Nata River / Ishikawa), *Lyriothemis pachygastra* (Mihama/Fukui), and *Onychogomphus viridicosta* (Kanazu, Fukui). *Indolestes peregrinus* is spreading into the Kaga district/Ishikawa; oviposition into young rice stem has repeatedly been observed at Daishoji. Influenced by the climatic conditions of 1998, seasonal appearance of several Odonata was advanced considerably: e. g. mating and oviposition of *Enallagma boreale circulatum* were observed in early May at a pond in a hilly region of Komatsu. The succession of the odonate fauna in newly formed ponds in Kanazawa, was documented by mainly collecting exuviae. Within 6 years, 46 species were recorded from this sanctuary. Both northern (e. g. *Coenagrion lanceolatum*) and southern (e. g. *Anaciaeschna martini*) species coexist in these ponds.] Address: Taketo, A., 1-19, Ishibiki 1-cho, Kanazawa City, 920, Japan

- 3115.** Aoki, T.; Kondoh, S. (1999): A note on reproductive behaviour of *Sympetrum striolatum imitoides* BARTENEV in Kobe. *Aeschna* 35: 37-40. (in Japanese with English summary). [Compared with other Japanese *Sympetrum*-species, with the exception of *S. uniforme*, pre-reproductive behaviour of ♂ *S. striolatum imitoides* seems to be unique. Their continuous hover flight starts just before ♀♀ arrive at the water for oviposition (about 10:30 J.S.T.), and lasts for about an hour. At the same time other ♂♂ wait for ♀♀ perching around the pond. Apparently two tactics for mating are used.] Address: Aoki, T., Rokko Island High School, Naka 4-chome, Koyo-cho, Higashinada-ku, Kobe, 658-0032, Japan. E-mail: taoki@ma3.justnet.ne.jp
- 3116.** Clausnitzer, V. (1999): Dragonfly (Odonata) records of Kawamega Forest, western Kenya, with notes on the ecology of rain forest species. *Journal of East African Natural History* 88 (2003): 17-23. (in English). [The list of 51 recorded Odonata includes ten new records for Kenya. "Some of the species have their centre of distribution in West Africa. Ecological notes on different adaptation strategies of rain forest dragonflies are given, mainly focusing on visibility and flight behaviour of the ♂♂. Seasonality patterns of the observed dragonflies and distinct behavioural features of selected species, e.g. *Hadrothemis* and *Gynacantha* are described." (Author)] Address: Clausnitzer, Viola, Liebenauer Str. 180, D-06110 Halle/Saale, Germany. E-mail: we-sche@mail.uni-marburg.de
- 3117.** Deliry, C. (1999): Nouveaux articles ou études concernant les libellules dans la région Rhône-Alpes. *Sympetrum piémontais* 39: 9-11. (in French). [France; regional odonatological bibliography covering the period 1997/98 and abstracting unpublished expertises in most cases.] Address: Deliry, C., La Paluette, 2338 route de Belley, F-38490 Aoste, France
- 3118.** Deliry, C. (1999): Nouveaux articles ou études concernant les libellules dans la région Rhône-Alpes. *Sympetrum piémontais* 42: 17-21. (in French). [France; regional odonatological bibliography covering the period 1997-2000 and abstracting unpublished expertises in most cases.] Address: Deliry, C., La Paluette, 2338 route de Belley, F-38490 Aoste, France
- 3119.** Desmeules, M. (1999): Compte-rendu littéraire: Les Odonates du Québec. Par Jean-Guy Pilon et Denise Lagacé. 1998. Corporation Entomofaune du Québec, Chicoutimi, Québec. 367 pages. ISBN 2-9802763-2-4. *Nouv'Ailes* 9(3): 12. (in French) [Review] Address: Publisher: Entomofaune du Québec, 637, blvd Talbot, suite 108, Chicoutimi, QC G7H 6A4, Canada
- 3120.** Futahashi, R. (1999): Notes on unusual connection and copulation in some species of dragonflies. *Aeschna* 36: 47-56. (in Japanese with English summary). [25 cases of interspecific connection and copulation, 8 cases of triple-connection, and 4 cases of ♂-♂ tandems are documented.] Address: not stated in Japanese
- 3121.** Futahashi, R.; Futahashi, H. (1999): Records of large scale migration of *Sympetrum cordulegaster* (SELYS) and *Sympetrum depressiusculum* (SELYS) in 1997 and emergence of both species in 1998 at Toyama Pref. *Aeschna* 36: 33-42. (in Japanese with English summary). [Many migratory adults of both species were found during a period between 6 Oct. and 10 Nov. 1997 at the reclaimed land of Kairyumachi Sinmmato City Toyama Pref. Japan. Some immature specimen were likewise found there during 18 June and 7 Aug. 1998. "Some of them seemed to be very immature or just emerged. This fact suggests that these species emerged there although neither larvae nor exuviae have been found." Intermediate specimens between *S. depressiusculum* and *S. frequens* were recorded at the same locality.] Address: not stated in Japanese
- 3122.** Haase, P. (1999): Zootaxonomie, Chemismus und Struktur regionaler Biotypen im niedersächsischen und nordhessischen Bergland. *Ökologie und Umweltsicherung* 18. 157 pp., appendix. (in German with English summary). [From 1996 to 1999 limnological investigations on upper courses of near natural brooks of the mountainous areas of Lower Saxony and northern Hesse (Germany) were carried out. The aim of these studies was the development and description of a regional typology of brooks. In total more than 200 macrozoobenthos species including *Cordulegaster boltonii* and *Thecagaster bidentata* were found.] Address: Univ.-Gesamthochschule Kassel, Fachgebiet Landschaftsökologie und Naturschutz, Nordbahnhofstr. 1a, D-37213 Witzenhausen, Germany
- 3123.** Hujihara, H.; Adati, T. (1999): Records of the emergence of *Macromia daimoji* OKUMURA from Asida river at Hiroshima Prefecture. *Aeschna* 36: 57-58. (in Japanese). [Japan; five records from May and June 1998 are documented.] Address: not stated in English
- 3124.** Hutchinson, R. (1999): Rayon Entomologie: Corbet, P.S. 1999. *Dragonflies: Behaviour and ecology of Odonata*. Comstock Publishing Associates, Ithaca NY. 829 pp. *Nouv'Ailes* 9(3): 7. (in French) [Review of Philip Corbet's outstanding book.] Address: Hutchinson, R., 12, chemin de la Savane, apt. 12, Gatineau (Québec), Canada, J8T 1P7
- 3125.** Itoh, S. (1999): A ♂ *Aeshna juncea* (L.) that misidentified a dead branch as a female. *Aeschna* 35: 51. (in Japanese). [Photodocumentation] Address: Itoh, S., Kinoshita 4-9-7-102, Wakabayashi-ku, Sendai-shi, Miyagi, 984-0047 Japan
- 3126.** Katatani, N.; Muraki, A. (1999): Records of the Odonata taken in Palau, Part II. *Aeschna* 35: 9-22. (in Japanese with English summary). [The Libullidae of Palau, Caroline Islands are treated in some detail. Observations were made from 27 Feb. to 1 Mar. 1996. "*Agrioptera cardinalis* is forest-hunting insects and is chiefly confined to lower altitudes. Adults are usually most abundant near the seacoast. The mature ♂♂ hold territories in shady places of jungle marshes and pools behind the beach. ♀♀ may wander far from their breeding places, congregating in sunlit spots and clearings. Further, many individuals settle on the branches of mangroves [...]. *Neurothemis t. terminata* is a very common and widespread species, occurring in both grassland and marsh. As to extent of brown wing color, ♂♂ form a homogeneous series. ♀♀ have androchromatic wings and heterochromatic wings." ♀♀ with androchromatic wings dominate on heterochromatic in Palau. "♂♂ of *Rhyothemis phyllis vitellina* have two large brown spots on base of hind wing separated by opaque

yellow coloring. On the other hand ♀♀ are with polychromatic wing pattern and very variable as to extent of dark marking." *Ischnura senegalensis* and *Orthetrum s. sabina* are added new to the list of Odonata of Palau, now totalling in 20 species. Colour patterns of ♂ synthorax, ♂ genitalia and caudal appendices of *Agrionoptera cardinalis* Lieftinck 1962 (Palau) are compared with *A. sanguinolenta* Lieftinck, 1962 (Truk, Guam), and *A. insignis* (Rambur 1842) (Iriomoete Islands, Palawan Islands, Mindanao, Philippines).] Address: Muraki, A., Shigino-nishi 3-4-2-309, Jôtô-ku, Osaka C., Osaka 536, Japan

3127. Kawashima, I.; Itoh, S. (1999): Notes on the last instar larva of *Somatochlora alpestris* (Selys, 1840) (Odonata, Corduliidae) from Hokkaido, Northern Japan. *Aeschna* 36: 25-31. (in English, with Japanese summary). [The external morphology of the last instar larva of *S. alpestris* from Hokkaido, Japan is described and illustrated in detail.] Address: Kawashima, I., Nagasawa 1-50-9, Yokosuka-shi, Kanagawa, 239-0842 Japan

3128. Kishi, K. (1999): Records of the Odonata in Bali Island, Indonesia. *Aeschna* 35: 23-35. (in Japanese with English summary). [Ten collecting trips to Bali between Dec. 1984 and April 1991 totaled in 42 odonate species; additional material referred in the paper rises the number of Odonata to 44. The author discusses the difference in faunal composition between the western and eastern part of Bali; four odonate taxa are known only from the western part. The records are documented in detail, some of the species are illustrated with black and white photos.] Address: not stated in English

3129. Kitagawa, K.; Ichii, H. (1999): Records of the Odonata from Southern Thailand. *Aeschna* 36: 59-68. (in Japanese with English summary). [62 species were taken at Trang, southern Thailand in 1991. The list includes an undescribed *Macromia*, which is illustrated by drawings and a black and white photo. In addition, *Tetrathemis irregularis hyalina* Kirby, *Drepanosticta khao-chongensis*, *Euphaea pahyapi*, *Aciagrion borneense*, *Rhinagrion mima*, *Macrogomphus borikhanensis*, *Megalogomphus sumatranus*, *Macromia chaiyaphumensis*, and *Macromia cupricincta* are stressed or documented by black and white photos.] Address: Kitagawa, K., Ima-iti 1-11-6, Asahi-ku, Osaka C., Osaka, 535-0011, Japan

3130. Kitagawa, K. (1999): Rediscovery of *Lin-aeschna polli* from Borneo. *Aeschna* 35: 41-42. (in Japanese). [*L. polli* was recorded in March 1997 at Kimanis Road (Crocker Range), Sabah, Borneo, Malaysia.] Address: Kitagawa, K., Ima-iti 1-11-6, Asahi-ku, Osaka C., Osaka, 535-0011, Japan

3131. Lissak, W. (1999): Erstnachweis für Bodenständigkeit des Südlichen Blaupfeils (*Orthetrum brunneum*) im Landkreis Göppingen. *Naturkundliche Mitteilungen Landkreis Göppingen* 18: 4-5. 3156. Cordero Rivera, A. (2000): An analysis of multivariate selection in a non-territorial damselfly (Odonata: Coenagrionidae). *Etologia* 8: 37-41. (in English with Spain summary). ["The relationship between fitness and phenotypic traits (body, thorax and wing length, head width and date of emergence) was studied in a sample of 187 ♂♂ and 113 ♀♀ of *I. graellsii* by means of a multivariate regression analysis of selection. ♂ fitness was estimated as lifetime mating success divided into three multiplicative episodes: lifespan, visits / lifespan and matings/visit (mating efficiency). In ♀♀, reproductive success was estimated from the lifetime number of ovipositions divided into lifespan, visits / lifespan and ovipositions/visit. Results indicated the absence of directional selection but highly significant nonlinear selection was observed in both sexes in respect to the date of emergence and body proportions. These results suggest that selection acts simultaneously on the multivariate phenotype and several traits should therefore be included in the selection analysis." (Author)] Address: Cordero Rivera, A., Departamento de Ecología e Biología Animal, Universidade de Vigo, E.U.E.T. Forestal, Campus Universitario, 36005 Pontevedra, Spain. E-mail: acordero@uvigo.es

3157. Donnelly, N. (2000): Farangpo 2000 - Hong Kong, Thailand and Cambodia. *Malangpo* 17: 160-162. (in English). [Odonatological report of a trip to these 3 Asian countries.] Address: Donnelly, T., 2091 Partridge

Lane, Binghamton, NY 13903, USA. E-mail: tdonnel@binghamton.edu

3158. Donnelly, T.W. (2000): Change in *Cannaphila insularis* common name. *Argia* 12(3): (in English). [Verbatim: "The Common Names Committee of the DSA has changed the common name of *C. insularis* (Libellulidae) from Narrow-winged Skimmer to Gray-waisted Skimmer. This change was to accommodate the necessity of giving *Cannaphila vibex* a common name, as the latter species was recently reported from Nuevo Leon, Mexico, and thus will be included in the new dragonfly manual by Needham, Westfall, and May (in which numerous species found in the northernmost Mexican states and the Caribbean islands will first be given English names). The name "narrow-winged skimmers" is being retained for the genus *Cannaphila*, and the most obvious field mark of *C. insularis*, the gray pruinosity at the base of the black abdomen of mature ♂♂, is now featured in its common name."] Address: Donnelly, T., 2091 Partridge Lane, Binghamton, NY 13903, USA. 3163. Donnelly, T.W. (2000): Na-Nick of the north strikes again - a visit to Churchill, Manitoba. *Argia* 12(3): 12-13. (in English). [Manitoba, Canada; 9 species were collected including *Aeshna septentrionalis*. A brief note on roosting site selection of *A. sitchensis* (warm,

gravel road and others), and *A. septentrionalis* (large granite glacial boulders). Species started to fly at temperatures of 14°C.] Address: Donnelly, T., 2091 Partridge Lane, Binghamton, NY 13903, USA. E-mail: tdonnel@binghamton.edu

3164. Dunkle, S. (2000): Fun in Oz. *Argia* 12(3): 15-18. (in English). [This is a nice talk on Odonata based on a four month trip to Australia, and how to spot them.] Address: Dunkle, S., Biol. Dept, Collin County Community College, 2800 E, Spring Creek Parkway, Plano, TX 75074, USA

3165. Futahashi, R.; Futahashi, H.; Araki, Y (2000): Supposed records on migration of *Sympetrum depressusculum* (SELYS). *Aeschna* 37: 28-30. (in Japanese). Address: not stated in English

3166. Glotzhober, B. (2000): Bernie V. Counts Jr., Ohia, dead at 42. *Argia* 12(3): 3-4. (in English). [obituary] Address: Glotzhober, R., Ohio Natural History Society, 1982 Velma Ave., Columbus OH 43211-2497, USA. E-mail: bglotzhober@ohiohistory.org

3167. Hämäläinen, M. (2000): Additions and corrections to dragonfly lists of five protected areas in Thailand. *Malangpo* 17: 156-157. (in English). [Additions to previously reported Odonata of Khao Yai National Park, Khao Soi Dao Wildlife Sanctuary, Doi Suthep - Pui national Park, Phu Kradung National Park, and Doi Inthanon National Park are made. Some species reported are critically discussed.] Address: Hämäläinen M., Dept Applied Zool., P.O.Box 27, FIN-00014 University of Helsinki, Finland; E-mail: matti.hamalainen@helsinki.fi

3168. Hämäläinen, M.; Yeh, W.-C. (2000): Polycanthagyna ornithocephala - again a new aeshnide to the Thai fauna. *Malangpo* 17: 158-159. (in English). [2 ♀♀ of *P. ornithocephala*, new additions to the Thai fauna, were caught at Kanchanaburi province, Kroeng Kra Via alt 22 Oct. 1999. One of the specimens is described in detail, and the species' distribution is briefly outlined. The species is compared with *P. erythromelas* and *P. melanictera*. In addition, habitat and habits are briefly described. *Tetracathagyna waterhousi*, a likewise rare species in Thailand, is reported from the same place from 2 May 2000.] Address: Hämäläinen M., Dept Applied Zool., P.O.Box 27, FIN-00014 University of Helsinki, Finland; E-mail: matti.hamalainen@helsinki.fi

3169. Hernández, J.M. (2000): Geographic distribution of *Crocothemis servilia* (Drury) (Odonata: Libellulidae) in Cuba. *Argia* 12(3): 28-29. (in English). [The Asiatic *C. servilia* was first recorded on Cuba in Dec. 1994; the present knowledge, based on collection of the author in successive years, is documented.] Address: Hernández, J.M.R., Apartado Postal 2004, Sancti-Spiritus, Cuba CP 60100

3170. Hutchings, G. (2000): DSA annual meeting, 27 July - 1 August 2000, British Columbia. *Argia* 12(3): 4-6. (in English). [Canada, British Columbia; this report includes lists of species collected in the framework of the meeting.] Address: Hutchings, G., 971 Arundel Drive, Victoria BC, Canada V9A 2C4

3171. Ishizawa, N. (2000): Aka-tombo at Otemachi in 1999. *Symnet* 8: 9-10. (in English). [Counts of *Sympetrum frequens*, *S. infuscatum*, and *S. darwinianum* are presented and discussed. "It is likely that because

of continuation of the climate change, the period of descent from highlands in *S. frequens* may be later than usual."] Address: Ishizawa, N., 1644-15, Yamaguchi, Tokorozava City, Saitama Pref., Japan. E-mail: isizawa7@mars.ccn.ne.jp

3172. Ishizawa, N. (2000): Articles on Aka-tombo in newspapers. *Symnet* 8: 2-3. (in English). [Finding a note in a more popular book on insects on a migratory swarm of *Sympetrum frequens* at June 21, 1973, the register of the regional newspaper was consulted to find out more details on this mass swarm. Disappointingly, only very few information on the migration were to extract from the newspapers. Some additional notes on articles with information of Odonata are listed, and the reasons are discussed why so little information on Odonata is present in newspapers.] Address: Ishizawa, N., 1644-15, Yamaguchi, Tokorozava City, Saitama Pref., Japan. E-mail: isizawa7@mars.ccn.ne.jp

3173. Ishizawa, N. (2000): *Sympetrum frequens* at Omori Pond (3). *Symnet* 8: 10-11. (in English). [In *S. frequens* more fertilized eggs were found in mid autumn than in early or late autumn. Data on larval growth, size of sexes at emergence, and the start of reproduction period are presented.] Address: Ishizawa, N., 1644-15, Yamaguchi, Tokorozava City, Saitama Pref., Japan. E-mail: isizawa7@mars.ccn.ne.jp

3174. Ishizawa, N. (2000): Thermoregulation in calopterygid damselflies. *Nature & Insects* 35(11): 14-17. (in Japanese). [This is a detailed survey of the thermoregulation in *Mnais pruinosa costalis* and *Calopteryx cornelia* in Japan. Mean thoracic temperature, mean weight, thoracic length, and wing loading are measured and compared. "In the orange-wing ♂, the relation of the temperature of thorax (Tth) to the ambient temperature in the sun was highly correlated and the regression coefficient was larger than 1.0, while in the hyaline-wing ♂, those coefficients were lower, and Tth of the latter was highly thermoregulated. So was the immature hyaline-wing ♂, too [...]. The experiment (the bodies except wings were covered and exposed to the light of 75 W halogen lamp from over 25 cm) proved that wing colour did not affect thoracic temperatures. Immature adults thermoregulated their thoracic temperatures rather lower than mature adults. Tth of the hyaline-wing ♂ increased higher than the orange-wing ♂, probably due to their lighter weight and the scantiness of pruinescence. In orange-wing ♂♂ their bodies were heavily pruinose and this may reflect the sunshine and keep Tth not so high in the direct sunshine. But due to it they can not be superior to hyaline ♂♂ at small sunlit spaces in the shaded areas, while hyaline-wing ♂♂ are superior in such areas. The ♀ of *M. p. costalis* has a relatively large thorax and this may be common among damselflies. This may be helpful for ovipositing ♀♀ to prevent from losing Tth in the water. In a ovipositing ♀ of *Cercion sieboldii*, Tth was lower by 3.8°C than that of her partner, and the difference was far larger than that (0.2°C) of other pairs ovipositing on the surface of water. ♀♀ of *M. p. costalis*, of which wing loading is larger are said to perch on the canopies of trees in the daytime except during oviposition to maintain high Tth. In ♂♂ of *C. cornelia*, they perch nearby streams or on boulders stuck out from the streams, so their Tth are low and their wing beat frequency is small. But their wing loading is light and they can fly easily, though they are not so agile." A translation of the paper is available from Naoya Ishiza-

wa, or IDF.] Address: Ishizawa, N., 1644-15, Yamaguchi, Tokorozavva City, Saitama Pref., Japan. E-mail: isizawa7@mars.ccn.ne.jp

3175. Kano, K.; Yokoi, N. (2000): On the plant worms of Odonata. *Nature & Insects* 35(11): 6-9. (in Japanese (translated in English by Naoya Ishizawa)). [A parasitic fungus belonging to the Clavicipitaceae, Ascomycota was found on *Sympetrum infuscatum*, Yasato-cho, Ibaraki Pref, Japan. The paper describes the infection route and compiles reports with information on "plant worms" on Odonata. A translation of the paper is available from Naoya Ishizawa, or IDF.] Address: Yokoi, N., 2-37-11 Kaisei, Koriyama, Fukushima, 963-8851 Japan

3176. Karube, H. (2000): Records of the New Caledonian Odonata. *Aeschna* 37: 37-42. (in Japanese). [26 species are listed; *Isosticta robustior*, *Caledopteryx maculata*, *Oreaeschna dominatrix*, *Synthemis miranda*, *Synthemis fenella*, and *Metaphya elongata* are documented by black and white photos.] Address: Karube, H., Kanagawa Prefect. Dubouchet: *Suivis spatial et temporel d'une population d'Orthetrum brunneum sur la Seymaz (GE)*. 7. R. Hoess: *Libellenbeobachtungen im Kanton Bern in Zusammenhang mit dem Jahrhunderthochwasser vom Mai 1999*] Address: CSCF, Terreaux 14, CH-2000 Neuchâtel, Switzerland

3183. Matsumura, T.; Uéda, T. (2000): A report on the vertical distribution of Aka-tombo on Akausage, Fukui Pref. and marking survey of *Sympetrum frequens*. *Symnet* 8: 6-8. (in English). [The distribution of *S. frequens*, a species known to disperse in summer to higher altitudes, was studied along a transect at 14 different elevations. The abundance increased significantly above 1000m a.s.l. Additional data are presented for *S. infuscatum*, *S. darwinianum*, and *S. eroticum*. Marking of 709 specimens of *S. frequens* resulted in a recapture of an individual 72 km apart from the marking locality.] Address: Ueda, T., Ishikawa Agricultural College, Suetatsu, Nonoichi, Ishikawa Pref., 921, Japan

3184. Mauffry, B.; Roble, S.; Tennesen, K. (2000): New state records of Odonata for West Virginia in the collection of the late Paul D. Harwood. *Argia* 12(3): 29-31. (in English). [USA; West Virginia; Based on a collection of app. 5000 specimens, three new state records could be added to the list of West Virginia Odonata: *Lestes inaequalis*, *Pantala flavescens*, and *Pantala hymenaea*. Some of the voucher specimens and publications of Harwood are critically discussed.] Address: Mauffray, B., 4525 N.W. 53rd Lane., Gainesville, FL 32653, USA. E-mail: iori@afn.org

3185. Nakai, K. (2000): Watching a migration of Aka-tombo in swarms. *Symnet* 8: 2. (in English). [Japan; 27 July, 1991 a swarm of migrating *Sympetrum frequens* was observed. It is described in detail. The number of the involved (mature) specimens is estimated at 800000 per hour.] Address: Nakai, K., Tsubata-machi, Kahoku-gun, Ishikawa Pref., Japan

3186. Nikula, B. (2000): Bog hopping and stream sloshing in the Maine woods. *Argia* 12(3): 10-12. (in English). [84 odonate species were collected in end of June, 2000 in the northeastern part of Maine, USA. *Anax longipes* is an addition to the Maine Odonata list. *Somatochlora hineana* could - contrary to 1999 - not be traced, but the quite recently described *Neurocordulia michaeli* Brunelle, 2000 was. The most interesting spe-

cies are listed locality-wise.] Address: Nikula, B., 2 Gilbert Lane, Harwich Port, MA 02646, USA. e-mail: ode-news@capecod.net

3187. Paulson, D. (2000): New records from Washington and Idaho. *Argia* 12(3): 25-26. (in English). [Records of *Coenagrion interrogatum*, *Aeshna subarctica*, *Nehalennia irene*, and *Epitheca spinigera* are documented in detail.] Address: Paulson, D.R., Slater Museum, Univ. of Puget Sound, Tacoma, WA 98416, USA. E-mail: dpaulson@ups.edu

3188. Sasamoto, A.; Ushijima, K (2000): Records of the Odonata collected at Kathmandu Valley, in Nepal. *Aeschna* 37: 1-12. (in Japanese with English summary). [Between 1997 and 1999, 50 species were recorded. Some are illustrated by black and white photos (*Rhincocypha trifasciata*, *Coeliccia renifera*, *Ceriagrion fallax*, *Gynacanthaeschna sikkima*, *Cephalaeschna masoni*, *Aeshna petalura*, *Anaciaeschna donaldi*, *Scalmogomphus bistrigatus*, *Macromia moorei*, *Sympetrum haematoneura*) or drawings (*Aciagrion olympicum*, aberrant *Crocothemis* sp.).] Address: not stated in English

3189. Tabata, O.I. (2000): A Record of *Lyriothemis elegantissima* Selys from Tokunosima Island. *Aeschna* 37: 27. (in Japanese). [Japan, 13-VII-1999] Address: Tabata, O., Shoubuen-cho 79-18, Kamigamo, Kita-ku, Kyoto C., Kyoto 603-8064, Japan

3190. Thiele, V.; Berlin, A.; Wichert, R. (2000): Zur Kenntnis zoologischer Taxa (Avifauna, Lepidoptera, Trichoptera, Odonata, Saltatoria) im Bereich von Knochenhauerwiese und Galgenbruch (Hansestadt Rostock). *Archiv der Freunde der Naturgeschichte in Mecklenburg* 39: 85-104. (in German). [Mecklenburg-Vorpommern, Germany; 20 odonate species are listed for three localities. The list includes *Aeshna viridis* and *Leucorrhinia pectoralis*.] Address: Thiele, V., biota, Am Augraben 2, D-18273 Güstrow, Germany

3191. Tsubuki, T. (2000): A record of *Sympetrum darwinianum* at the Yunomaru heights. *Symnet* 8: 8-9. (in English). [Japan; some altitudinal records of (mature) *S. darwinianum*, and observations on pre-reproductive *S. frequens* are reported.] Address: not stated

3192. Tsubuki, T. (2000): Observation on *Sympetrum frequens* and *Sympetrum darwinianum* at Soja City, Okayama Pref. in the early November. *Symnet* 8: 9. (in English). [Japan; faunistic data on the two species] Address: not stated

3193. Tsubuki, T. (2000): Seasonal fluctuations of Aka-tombo in the peripheries of Mogusayama, Hino City, Tokyo in 1997. *Symnet* 8: 11-13. (in English). [Japan; detailed documentation of seasonality of *Sympetrum frequens*, *S. infuscatum*, *S. speciosum*, *S. darwinianum*, and *S. eroticum* between July and December 1997.] Address: not stated

3194. Ueda, T. (2000): "The Japanese" and dragonflies. *Symnet* 8: 1. (in English). [The paper documents the title pages of the journal "The Japanese" which first was published in 1888, the 21th year of the Meiji era. Obviously it was a nationalistic magazine aimed to try to avoid europeanism in Japan. Some of the items of the journal referring to Odonata are briefly noted, and the special relationship between Japan (Akit-sushima - Country of Dragonflies) and dragonflies is

briefly outlined.] Address: Ueda, T., Ishikawa Agricultural College, Suematsu, Nonouchi, Ishikawa Pref., 921, Japan

3195. Ugai, S. (2000): Hybrid records of dragonflies in Japan. *Nature & Insects* 35(11): 18-22. [The paper documents and compiles extensively hybrids between odonate species in Japan. A translation of the paper is available from Naoya Ishizawa, or IDF.] Address: not stated

3196. Ushiyama, M. (2000): Rescue works of larvae in swimming pools. *Symnet* 8: 5. (in English). [The author describes the situation of school ponds in Japan used for swimming purposes; cleaning of the ponds prior emergence of Odonata leads to the destruction of the dragonfly population. The author describes who it may be possible to combine the functions "swimming pond for pupils" and "habitat of Odonata".] Address: not stated

3197. Wagner, D.L. (2000): Dragonfly and damselfly workshop, University of Connecticut. *Argia* 12(3): 8. (in English). [Report from a workshop organised in May 2000.] Address: Wagner, D.L., Ecol. & Evol. Biology, U. Box 42, Univ. Connecticut, Storrs, CT 06269, USA. E-mail: dwagner@uconnvm.uconn.edu

3198. Watanabe, K. (2000): *Coeliccia* of Thailand and Malaysia. *Nature & Insects* 35(11): 2-5. (in Japanese (translated in English by Naoya Ishizawa)). [The paper lists all known species of the genus *Coeliccia* in table along with the countries they occur. Areal maps and information on altitudinal distribution of *C. didyma* (Selys 1863), *C. pounyi* Fraser 1924, *C. loogali* Fraser 1932, *C. chromothorax* (Selys 1891), and *C. doisuthensis* Asahina 1984 are presented. *C. cyanomelas* Ris 1912, *C. flavicauda* Ris 1912, and *C. ryukyuensis* Asahina 1951 are discussed from the evolutionary point of view. A translation of the paper is available from Naoya Ishizawa, or IDF.] Address: not stated

3199. Watanabe, Y. (2000): Attachment apparatus of dragonfly eggs. *Nature & Insects* 35(11): 10-13. (in Japanese (translated in English by Naoya Ishizawa)). [Eggs are enclosed by a gelatinous substance which is interpreted as an adaptation to protect the eggs. The substance is discussed from an evolutionary point of view. Eggs and their specific attachment apparatus are documented for the followings species: *Ischnura asiatica*, *Copera annulata*, *Anax parthenope julius*, *Stylurus annulatus*, *Asiagomphus amamiensis*, *Gomphus postocularis*, *Nihonogomphus viridis*, *Sinictinogomphus clavatus*, *Onychogomphus forcipatus*, *Sympetrum frequens*, *Epitheca bimaculata sibirica*, and *Deielia phaon*. A translation of the paper is available from N. Ishizawa, or IDF.] Address: Watanabe, Yoko, 4-14, Nishida-cho, Nishinomiya City, Hyogo Pref., 662-0034, Japan

3200. Yokoyama, T. (2000): Notes on the durations of the egg stages on some dragonflies in Hokkaido 2. *Aeschna* 37: 22-26. (in Japanese). [*Mnais pruinosa*, *Lestes sponsa*, *Sympecma paedisca*, *Coenagrion e-cornutum*, *C. hylas*, *Enallagma circulatum*, *Nehalennia speciosa*, *Gomphus postocularis*, *Davidius moiwanus*, *Trigomphus melampus*, *Oligoaeschna pryeri*, *Aeshna juncea*, *A. nigroflava*, *Somatochlora viridiaenea*, *S. arctica*, *S. alpestris*, *Cordulia aenea*, *Epitheca bimaculata*, *Lyriothemis pachygastra*, *Sympetrum frequens*, *S. darwinianum*, *S. infuscatum*, *S. eroticum*, *Sympetrum kun-*

ckeli, S. risi, S. flaveolum, Sympetrum danae, Leucorhinia intermedia.] Address: Yokoyama, T., 1-15-303, Higashi 22chome, Kita 19jo, Higashi-ku, Sapporo City, 065, Japan

3201. Yoshida, M. (2000): Collecting and breeding data of some odonate larvae, 3rd report. *Aeschna* 37: 13-21. (in Japanese with English summary). [Japan; 19 species are treated.] Address: not stated in English

3202. Yoshida, M. (2000): Dispersive record of *Boyeria maclachlani* (SELYS) at Yahagi River. *Aeschna* 37: 28. (in Japanese). Address: not stated in English

3203. Zschunke, R. (2000): Untersuchungen zum Einfluss des Wetters auf das Verhalten der Gebändernten Prachtlibelle (*Calopteryx splendens*) unter besonderer Berücksichtigung der Reviermännchen. Diplomarbeit im Fachbereich Biologie (Zoologie) der Universität des Saarlandes. 100 pp. (in German). [River Nied, Saarland, Germany; Effects of weather on *C. splendens* were surveyed in 1999; special emphasis was given to territorial ♂♂. Meteorological data (air-temperature, 400 - 700nm - radiation, UV-radiation, wind speed, relative atmospheric humidity, and rain / precipitation) were measured continuously. These data were plotted against the dynamic of the population and the behaviour of selected specimens. Air temperature and visible radiation determined the behaviour of *C. splendens* predominately. Wind velocity influenced the behaviour. Atmospheric humidity was equal at maturation places and territories; there was no indication that teneral specimens prefer places with higher humidity than mature specimens. In addition, this M.Sc. includes observations on behaviour of *C. splendens* during the solar eclips of 11/08/1999, and many additional information on population dynamics, sex-ratio, roosting site selection, diurnal activity, etc. This study provides highly significant information on the influence of weather on the behaviour of Odonata.] Address: Zschunke, R. E-mail: rasz@gmx.de

2001

3204. Abbott, J. (2001): The 2001 DSA annual meeting at Junction, Texas. *Argia* 13(3): 2-4. (in English). [*Erythemis peruvia* - new to the USA - was collected at the South Llano River State park, Texas. In addition species lists from several localities in Texas and New Mexico, USA are provided.] Address: Abbott, J.C., Patterson Labs 219, School of Bio. Sci., University of Texas, Austin TX 78712, USA. E-mail: jcabbott@mail.utexas.edu

3205. Akagi, M. (2001): Observation on a swarming aka-tombo. *Symnet* 9: 5. (in English). [Japan, Miyauchi, Tottori, Pref.; July 3, 2001, report on an aggregation of *Sympetrum frequens*.] Address: Akagi, M., Nichinancho, Hino-gun, Tottori Prefecture, Japan

3206. Araki, Y.; Futahashi, R. (2001): Record of collecting and breeding of larvae of *Anax guttatus* in Toyama Prefecture. *Aeschna* 38: 35-38. (in Japanese with English summary). ["We collected some larvae of *A. guttatus* at Daimon-machi and Asahi-machi, Toyama Prefecture in October and November 1998. This is probably the northernmost record of the larvae of this tropical migratory species in Japan. According to our

breeding data the egg period was 11 to 19 days, and the larvae period was 55 to 88 days. Hence, the larvae we collected outdoors are supposed to have been originated from the eggs laid in August and September 1998 In 1998 autumn, we found many adults of *Anax guttatus* but it was not easy to find the larvae mainly because of the difficulty in identifying young larvae. But we also speculate that the eggs or the young larvae of this species could not adequately adapt themselves to the cold climate of the late autumn in the Hokoku district because no late-stage larvae was found through our repeated research in October and November at Shimamoto-city and Himi-city (Toyama Prefecture) where we observed its reproductive behavior many times since September."] Address: not stated in English

3207. Barlow, A.E. (2001): Second annual report of the new Jersey Odonata Survey including a state record and numerous county records. *Argia* 13(3): 18-22. (in English). [*Somatochlora kennedyi* was discovered on June 7, 2001 in New Jersey, USA. 36 additional species to counties are briefly discussed.] Address: Barlow, A.E., 10 Belle Court, Budd Lake, NJ 07828, USA. 3211. Buidin, C. (2001): Premiere mention de *Sympetrum (Sympetrum) semicinctum* Say (Odonata: Libellulidae) par la Côte-Nord du Saint-Laurent. *Fabriques* 26(2): 82. (in French). [Quebec, Canada; 1 ♀, 9-IX-2000.] Address: Buidin, C., 1 ch. du Grand Ruisseau, Riviere-Saint-Jean, QC, G0G 2N0, Canada

3212. Daigle, J.J. (2001): Cades cove dragonfly bioblitz II. *Argia* 13(3): 6. (in English). [Report from a regional meeting including a list of twelve new species for the Great Smoky Mountains National Park, Tennessee, USA.] Address: Daigle, J., 2166 Kimberley Lane, Tallahassee, FL 32311, USA. E-mail: jdaigle@netally.com

3213. Deliry, C. (2001): *Sympetrum piémontais* n°1 à 46. Un retour sur les activités du GRPLS *Sympetrum piémontais* 47: 12-15. (in French). [The French "Groupe de Recherche et de Protection des Libellules

"Sympetrum" is definitely one of the most active dragonfly associations within our community of odonatologists. This paper compiles the essentials of the work starting in 1986/87 and is a significant document of dragonfly research in France.] Address: Deliry, C., La Paluette, 2338 route de Belley, F-38490 Aoste, France

3214. Donnelly, N. (2001): There are definitely no flying fishes on the road to Mandalay. *Argia* 13(3): 15-18. (in English). [Report from a collecting trip to Myanmar / Burma.] Address: Donnelly, T., 2091 Partridge Lane, Binghamton, NY 13903, USA. E-mail: tdonnel@binghamton.edu

3215. Futahashi, M.; Fukui, M; Yoshida, M.; Yokoyama, T. (2001): Breeding records of eggs and larvae of *Sympetrum depressiusculum* (Selys, 1841). *Aeschna* 38: 24-26. (in Japanese with English summary). [The authors outline that "previous breeding records regarded most of the offspring of *S. depressiusculum* caught in Japan as hybrids between *S. depressiusculum* and *S. frequens*." To obtain "genuine *S. depressiusculum*", specimens thought to have just reached the coastal area of Japan from overseas were caught. Eggs reared to the imago proved to be typical *S. depressiusculum*.] Address: Yokoyama, T., 1-15-303, Higashi 22chome, Kita 19jo, Higashi-ku, Sapporo City, 065, Japan

3216. Futahashi, R.; Futahashi, H.; Araki, Y. (2001): Observation of copulation and oviposition of *Sympetrum cordulegaster*. *Aeschna* 38: 39-40. (in Japanese with English summary). [Records of copulation behaviour of *S. cordulegaster* in Japan are rare. The authors present photographs of the copulation and oviposition ("Flying-oviposition into the water") of this species.] Address: not stated in English

3217. Gianti, M. (2001): Segnalazioni faunistiche italiane. *Coenagrion mercuriale* ssp. *castellani* Roberts, 1948 (Odonata: Coenagrionidae). *Boll. Soc. ent. ital.* 133(3): 267. (in Italian). [*C. castellani* is for the first time recorded for Piemonte, N Italy (1 ♂, 2 ♀♀, Salmour/CN, 13-VI-1999). Its distribution in Italy is briefly outlined.] Address: Gianti, M., Via Divisione Cuneese 17, I-12023 Garaglio CN, Italy

3218. Hachiya, K. (2001): Seasonal fluctuations of adult *Sympetrum frequens* and *Sympetrum infuscatum* at rice paddies in Hokkaido. *Symnet* 9: 6-9. (in English). [In 1998 and 1999, the emergence and pre-reproductive period of *Sympetrum frequens* and *S. infuscatum* was studied near Sapporo, Hokkaido, Japan.] Address: Hachiya, K., Kuriyama-cho, Yubari-gum, Hokkaido, Japan

3219. Higashi, K. (2001): Kotee of dragonflies and quails. *Symnet* 9: 1-2. (in English). [Japan; "Kotee is said to be an art of moulding on a plaster wall with only a trowel by a plasterer." This paper reports extensively on a kotee representing dragonflies.] Address: Higashi, K., Department of Applied Biological Sciences, Faculty of Agriculture, Saga University, Honjyo-machi 1, Saga, 840-8502, Japan. E-mail: higashik@cc.saga-u.ac.jp

3220. Ikezaki, Y. (2001): The extinct and seriously endangered species of insects in Nagasaki prefecture. *Nature & Insects* 36(11): 23-25. (in Japanese with English title). [Japan, the list of 5 insect species includes *Mortonagrion Hirosei*, and *Libellula angelina*.] Address: not stated

3221. Ishizawa, N. (2001): Capture of a ♀ *Sympetrum frequens* Selys with highly reflective wings. *Gekkan-Mushi* 370: 31-32. (in Japanese). [I captured a ♀ *S. frequens* of which wings were highly reflective at Mikajima, Horinouchi, Tokorozawa City, Saitama Prefecture on September 18, 2001. It was fine, and the air temperature was 29.113 at 2:50 p.m. The dragonfly perched on a rope, and was rather inactive in flight. The abdominal dorsum was dark brown; body weight: 301 mg, abdominal length: 28.7 mm, fore wing: 35 mm, hind wing: 33.5 mm, the total weight of four wings: 11 mg, rather heavier than those of ordinary ones (8.9+1.3 mg, n=16). The wings were glistening like those of teneral soon after emergence. The body sizes were not so different from ordinary ones except the fore wings. The ♀ had a large fore wings for its body, because such a dragonfly of which fore wings exceed 35 mm is rarely seen. I compared the dragonfly with ordinary ones on the effect of wings on body temperature by irradiating them with a halogen lamp (75W) from over 20 cm apart. Fig. 1 shows the changes of the odds of the body temperatures of the same ♀♀ before and after cutting off wings at intervals of 30seconds. Body temperatures (T_b) were measured with a thermocouple (diameter, 0.05 mm) connected to a digital thermometer by inserting the probe to the center of the 1 thorax, 1 mm up the mesothoracic spiracle. The starting T_b was 25°C (some specimens 23.5°C) at 22-24°C of indoor temperature. The odds of T_b of the highly reflective ♀ was 3.3 °C for 3 minutes, higher than those of the ordinary ones (1.3 ±0.4, n=10). I don't know why it was so high, however, the haemolymph might have remained inside the wings, absorbing the radiation heat of the lamp, and it might have been taken into the thorax. That might have raised the body temperature. In the same case as this, I saw a ♂ of the species at Sawairi in Mt. Nyugasa, Nagano Prefecture (1,450 m a.s.l.) (Ishizawa, 1988: *Nature & Insects* 23 (13): 28). The ♂ was not so active and weak in flight. If T_b was high, it must have flown actively, however, curiously it did not. Did it only look weak in fluttering because of the high reflection? Such cases have been reported; one ♂ and one ♀ of *S. frequens* were caught by Takasaki (1996: *Symnet* (5): 8), one ♂ by Udono (1997: *Symnet* (6): 4), and the dragonflies were said to be not so different from ordinary ones besides the physically high reflection. (Taken from *Digest Jap. Odonatol.* Short Comm. No. 12, February, 2002; fig 1 and photo 1 are omitted.)] Address: Ishizawa, N., 1644-15, Yamaguchi, Tokorozawa City, Saitama Pref., Japan. Homoptera, Coleoptera, Lepidoptera, Odonata, and Diptera, of which the portrayals of butterflies are the most numerous. In the dragonfly, its importance symbolically was probably due to its swift flight and the capacity of rapid change of direction. Thus, Native Americans equate it to the whirlwind, swiftness and activity. By Plains Indians, who used its image on shirts, it was regarded as a spirit helper in warfare. The dragonfly is also used in the jewelry of the Navajo and Zuni. There is a XII dynasty Egyptian dragonfly amulet, but its significance is unknown. It is the emblem of summer for Chinese, who also regard the dragonfly as a symbol of instability and weakness, almost matched by the Japanese regard of it as denoting irresponsibility and unreliability, but both these cultures use its image in adornment. Western jewelers employed it as a motif in 19th and 20th century jewelry."] Address: "Ornament" Ed. Office, P.O. Box 2349, San Marcos, CA 92079, USA

3238. Rodrigues, G.G.; Scharf, B.W (2001): Review of benthic invertebrate fauna in extremely acidic environments (pH < 3). *Mine Water and the Environment* 20: 114-121. (in English). ["Some benthic invertebrate species are able to colonise habitats in extremely acidic waters. We compiled a list of acid-resistant benthic invertebrates from the literature and extended it by studying extremely acidic mining lakes in eastern Germany. Acid-resistant species were registered for some habitats with pH < 3, such as volcanic-lakes, acid strip streams, and acidic mining lakes. Twenty nine taxa were found in waters with pH below 3. Diptera comprised 48.3% of the total number of taxa, followed by Coleoptera with 10.3%, Trichoptera 10.3%, Ephemeroptera, Megaloptera, and Plecoptera each with 6.9%, and Odonata, Hirudinea, and Acari each with 3.5%. Chironomus (Diptera: Chironomidae) were the most common genus in extremely acidic environments with 9 species. [...]"] (Authors) *Coenagrion mercuriale* is reported from a mining lake near Grünewalde, Brandenburg, Germany (13°34'E 51°30'N) with a pH value of 3. Comment: It should be considered that *C. mercuriale* in Brandenburg is extremely rare, only one locality is known (Mauersberger 2000), and that the described habitat should be quite exceptional for this species. The general discussion on acid water tolerance of Odonata by the authors ignores most significant literature on the subject, and even the fact that there are many bog dwelling species in Germany or world wide. In addition, none of the publications on the odonate fauna of the brown coal mining lakes in eastern Germany is considered.] Address: Rodrigues, G.G.; Scharf, B.W., UFZ - Centre for Environmental Research Leipzig-Halle, Dept of Inland Water Research, Magdeburg, Brückstr. 3 a, D-39114 Magdeburg, Germany. 3248. U.S. Fish and Wildlife Service (2001): Hine's Emerald Dragonfly (*Somatochlora hineana*) Recovery Plan. Fort Snelling, MN. 120 pp. (in English). [Verbatim: EXECUTIVE SUMMARY Hine's Emerald Dragonfly Recovery Plan Current Status: The Hine's emerald dragonfly, *Somatochlora hineana*, was listed as endangered in January 1995. Extant Hine's emerald dragonfly populations are currently known to persist in Illinois, Wisconsin, Michigan, and Missouri. The Illinois population is the most genetically diverse, and the Wisconsin populations are the largest and presumably most secu-

re. Information on the status of the Michigan and Missouri populations is limited because of their recent discoveries. Historically known from Ohio and Indiana, it is thought to be extirpated from these states. Habitat Requirements and Limiting Factors: The Hine's emerald dragonfly occupies marshes and sedge meadows fed by calcareous groundwater seepage and underlain by dolomite bedrock. In general, these areas are characterized by the presence of slowly flowing water and nearby or adjacent forest edges. Known occupied habitats are currently restricted to the lower Des Plaines River valley, in Illinois; northeastern Door County and Cedarburg Bog, Wisconsin; areas of the Hiawatha National Forest, in the Upper Peninsula of Michigan, three areas in the Lower Peninsula of Michigan, and at three fens in Missouri. Loss of this already rare and restricted habitat to agriculture, commercial and industrial development is the primary cause of the species' decline. Loss of remaining habitat from the same pressures, combined with successional change in the existing habitats and disruption of ecological and hydrological processes, are threats to surviving populations. Recovery Objectives: The objective of this recovery plan is to restore the Hine's emerald dragonfly to viable populations so that it may be removed from the Federal list of Endangered and Threatened Wildlife and Plants. Recovery Criteria: Each of the two Recovery Units contains a minimum of three populations composed of at least three subpopulations. Each subpopulation contains a minimum of 500 reproductive adults for 10 consecutive years. Within each subpopulation, there are at least two breeding habitat areas, each fed by separate seeps and/or springs. For each population, the habitat supporting at least three subpopulations should be legally or formally protected and managed for Hine's emerald dragonfly, using long-term protection mechanisms such as watershed protection, deed restrictions, land acquisition, or nature preserve dedication. In addition, mechanisms protecting the up gradient groundwater watershed should also be in place. Actions Needed: 1. Protect and manage extant populations 2. Conduct studies 3. Conduct searches for additional Hine's emerald populations 4. Conduct an information and education program 5. Conduct a reintroduction and augmentation program 6. Review and track recovery progress Total Cost of Recovery: The total estimated cost for the recovery actions outlined in this plan is \$13,163,000. These recovery actions will benefit not only the Mine's emerald dragonfly, but entire natural communities and other environmental amenities such as drinking water. Many of the actions described in this recovery plan are already funded by existing programs in agency and private organization budgets. The cost estimate represents expenditures over a 20 year time period. Date of Recovery: Full recovery of this species could occur within 10 years of initially meeting the recovery criteria for delisting. It is anticipated that recovery could occur as soon as 2019. This recovery plan has been prepared by the Mine's emerald dragonfly Recovery Team under the leadership of Dr. Dan M. Johnson with assistance in writing the document by Deanna Zercher of the Illinois Natural History Survey in Champaign, Illinois.] Address: U.S. Fish and Wildlife Reference Service 5430 Grosvenor Lane, Suite 110 Bethesda, Maryland 20814 301-492-6403 or 1-800-582-3421

3251. Yanoviak, S.P. (2001): The macrofauna of water-filled tree holes on Barro Colorado Island, Panama. *Biotropica* 33(1): 110-120. (in English). ["The fauna of water-filled tree holes in neotropical forests is not well documented. Cumulatively, 54 macroinvertebrate and 5 vertebrate taxa were found in artificial and natural tree holes censused over four wet seasons on Barro Colorado Island, Panama. Most of the species were in the insect order Diptera, occurred as aquatic larvae in tree holes, and were detritivore/omnivores. Half (49%) of the collected species are considered specialists in this and similar container habitats, and three invertebrate taxa were previously unknown from tree holes. Successional patterns were weak in the tree holes, but some taxa predictably colonized holes shortly after they were filled. The mosquito *Culex urichii* was more common and abundant in artificial than in natural tree holes; occurrence frequencies and densities of most other taxa were similar between hole types. [...] *Libellula* sp. was a very rare occupant in natural tree holes on BCI; the only natural tree hole occurrence of *Libellula* sp. was in large, highly insulated holes of a recently fallen *Platydiurn clegans* near a stream; however, this species sometimes colonized large artificial holes located in treefall gaps and was common in moats surrounding greenhouses. Larvae of the remaining five species of odonates - "*Gynacantha membranalis*, *Triacanthagyna dentata*, *Mecistogaster linearis*, *M. ornata*, and *Megaloprepus caerulatus*" - (along with larvae of the mosquito *Toxorhynchites theobaldi* and *Dendrobates auratus* tadpoles), were the top predators in tree holes. The behavior and ecology of these odonate species have been studied extensively by O. Fincke and S.P. Yanoviak." (Author)] Address: Yanoviak, S.P., Dept Zool., Univ. Oklahoma, Norman, Oklahoma 73019. USA

3252. Yokoyama, T. (2001): Notes on the duration of the egg stages of some dragonflies in Hokkaido. *Aeschna* 38: 9-12. (in Japanese). [Data of 27 odonate species from Hokkaido, Japan are presented.] Address: Yokoyama, T., 1-15-303, Higashi 22chome, Kita 19jo, Higashi-ku, Sapporo City, 065, Japan

3254. Zasybkina, I.A.; Ryabukhin, A.S. (2001): Amphibiotic insects of the Northeast of Asia. Pensoft, Sofia-Moscow & Backhuys, Leiden. ISBN 954-642-138-3 (Pensoft) & 90-5782-089-7 (Backhuys): vii+183 pp.- [An annotated list is presented of the 24 odonate taxa known to occur in NE Asia. Their regional distribution and habitat types are stated, and an exhaustive bibliography is provided. The records are not critically discussed as *Coenagrion lunulatum* and *C. vernale* nom.

nud. and *Sympetrum danae* and *S. scoticum* are treated each as valid species. *Enallagma antiquum* Barteneff, 1911 is also listed; the status of this taxon is unknown and not described in the paper of Barteneff listed in the bibliography.]

3255. Zawadzka D.; Zawadzki J. (2001): Breeding populations and diets of the Sparrowhawk *Accipiter nisus* and the Hobby *Falco subbuteo* in Wigry National Park (NE Poland). *Acta Ornithol.* 36: 25-31. (in English with Polish summary). [The diet composition of the two species was studied by the analysis of pellets and prey remains. Sparrowhawks fed on birds (97% of prey items, 99% of food biomass) and insects (43% of prey, 1% of biomass). Sparrowhawks specialized in forest birds, positively selecting *Parus* spp., *Turdus* spp., *Picidae* and *Ficedula* spp. Hobbies hunted mainly birds of open habitats (*Alauda arvensis*) and woodland (*Anthus trivialis*). As usually, Odonata are among the prey of the Hobby, but they account only 3,7 % of the prey items and 0,1% of the biomass. Surprisingly, in one case even Sparrowhawks preyed on Odonata.] Address: Zawadzka D., Zawadzki J., 25 Czerwca 68b/15, 26-600 Radom, Poland

2002

3256. Adriaens, T (2002): Dragonflies of the northern part of Western Flanders: status, importance and conservation. *Gomphus* 18(1-2): 15-40. (in Dutch, with English and French summaries). ["The odonatofauna of the north of the province West-Flanders (Belgium) is relatively well-known. This article deals with historical and recent distribution of observed species (31 in total) and aims to determine the most important sites (species diversity, rarity) for dragonflies. Sites were clustered in respect to species composition using TWINSPLAN software. Division levels were then displayed in a GIS-environment, so as to get an idea about the usefulness of the current ecodistricts in interpreting distribution patterns of dragonflies in the region. The Houtland ecodistrict, a region of pleistocene sands, appeared most species diverse, with the Bell Heather Reserve fen (Zevenkerke) displaying the highest species richness in the region (22 species). No less than three Red List species were recorded in this district, the latter probably being extinct: *Cordulia aenea*, *Leucorrhinia dubia*, and *Coenagrion pulchellum*. The ecodistrict "dunes" is important for the vulnerable *Ischnura pumilio*. It is suggested that ecodistricts might be too detailed for interpreting dragonfly distribution. Finally we present ideas for maintaining and managing populations of some delicate species." (Author) The following species are discussed in detail: *Sympecma fusca*, *Lestes barbarus*, *Ischnura pumilio*, *Coenagrion pulchellum*, *Cercion lindenii*, *Erythromma najas*, *Gomphus pulchellus*, *Cordulia aenea*, *Crocothemis erythraea*, *Leucorrhinia dubia*, and *Sympetrum fonscolombii*.] Address: Adriaens, T., Instituut voor Natuurbehoud, Kliniekstraat 25, B-1070 Brussel, Belgium. 3277. Cordoba-Aguilar, A. (2002): Sensory trap as the mechanism of sexual selection in a damselfly genital trait (Insecta: Calopterygidae). *American Naturalist* 160: 594-601. (in English) ["During copulation, males of some calopterygid damselfly species displace the sperm stored in the spermatheca: the male genital appendages enter into the spermathecal ducts and physically remove sperm. In *Calopteryx haemorrhoidalis*, the genital appendages are too wide to penetrate the spermathecae, but males use a different mechanism in which the aedeagus stimulates the vaginal sensilla that control spermathecal sperm release. Since these sensilla are used during egg fertilization and oviposition, it was hypothesized that this function evolved before the male stimulatory ability. I investigated this using *Hetaerina cruentata*, a species whose position in the Calopterygidae phylogeny is more basal than *Calopteryx*. Given this position and having determined that males of this species are not able to displace sperm of their conspecific females during copulation, it was expected that *H. cruentata* females would eject sperm when stimulated with the aedeagi of *C. haemorrhoidalis* but not when stimulated with the aedeagi of their conspecifics. This prediction was confirmed. In order to investigate the widespread nature of this result, some other Calopteryx species *Calopteryx xanthostoma* and *Calopteryx virgo* were investigated. The results were similar to those of *H. cruentata*: conspecific males were unable to stimulate their females, but females ejected sperm when stimulated with *C. haemorrhoidalis* aedeagi. Morphometric analysis suggests that the mechanistic explanation for the stimulatory ability of *C. haemorrhoidalis* genitalia is that the aedeagal region that makes contact with the vaginal sensilla is wider in *C. haemorrhoidalis* than in the other species. These results suggest that the sensory "bias" shown and shared by *H. cruentata*, *Calopteryx splendens*, *C. virgo*, and *C. haemor-*

rhoidalis females represents an ancestral condition and that the male stimulatory ability is absent in the evolutionary history of the clade. These pieces of evidence as well as another one presented elsewhere, which indicates that *C. haemorrhoidalis* males vary in their stimulatory ability, constitute the three criteria for a case of sexual selection via exploitation of a female sensory bias. These results also provide support to the sensory trap hypothesis that indicates that the female bias in this case, egg fertilization and oviposition evolved in a context different from sexual selection. Considering that the male genital appendages responsible for physically removing spermathecal sperm in other calopterygids are present in *C. haemorrhoidalis*, I suggest that males were once able to displace spermathecal sperm physically. Such ability may have been later impeded by a reduction in size of the spermathecal ducts. Possibly, one of the latest events in this sequence is the male's stimulatory ability. This hypothetical series of events suggests a coevolutionary scenario in which the central actor is the sperm stored in the spermathecae."] (Author) Address: Cordoba-Aguilar, A., Centro de Investigaciones Biológicas, Universidad Autónoma del Estado de Hidalgo, Apdo. 3278. Correia, A.M. (2002): Niche breadth and trophic diversity: feeding behaviour of the red swamp crayfish (*Procambarus clarkii*) towards environmental availability of aquatic macroinvertebrates in a rice field (Portugal). *Acta Oecologica* 23: 421-429. (in English). [*P. clarkii* (Girard 1852), "an alien species in Portugal, may have dramatic effects on aquatic communities by depleting all food resources available, just after its introduction. The purpose of this study was to evaluate, through the concept of niche breadth, whether the diet of this species reflected the temporal changes of aquatic macroinvertebrate availability once it is acclimated. Petraitis' index of niche breadth and Herrera's trophic diversity index were used to evaluate the trophic behaviour of *P. clarkii* towards available resources over time and intraspecifically (size classes and sex) in a rice field in Portugal. Results from this study showed that the consumption of aquatic macroinvertebrates by *P. clarkii* reflected their seasonal availability. The high values of niche breadth and trophic diversity indicated resource use according to trophic availability, diversified diets and different individual exploitation of resources regardless of size or sex. These findings suggest that in habitats where *P. clarkii* is already acclimated, it adjusted its trophic behaviour to the seasonal availability of aquatic macroinvertebrates. The large niche breadth and high trophic diversity presented by *P. clarkii* enables it to successfully expand its range to new areas, when other environmental conditions are favourable, as has been observed in Portugal and worldwide." (Author) In autumn, "Lestidae" belong to the diet of *P. clarkii*.] Address: Correia, Alexandra Manjal, Centra de Biologia Ambiental (CBA), Department Zoologia (Museu Bocage), Museu Nacional de Historia Natural, Universidade de Lisboa, R. 3279. Curry, J. (2002): Observations on *Neurocordulia*. *Argia* 14(3): 13-14. (in English). [From June to August 1999, *N. molesta* and *N. yamaskanensis*, were observed. Both species are extremely rare in Indiana, USA. They started their flight activities shortly before dusk, flying with an extraordinary speed. This short period of

time before getting dark, was used to pair and to feed. The author wonders how these Odonata could capture prey at such low levels of light, and how they could feed sufficiently in such a short period of time. There is evidence that the biomass over the river is as dense as a "soup" of small insects filling the air (based on collecting insects with a net driving with a boat on the river). "Based on this experience, I can't help wondering if the Shadowdragons were foraging by flying through the "soup" of tiny insects and scooping them up with their legs without ever targeting individual prey. The long spines of the tibiae could form a very nice net for sweeping tiny insects from the air. This would be similar to what some marine mammals do when plowing through a concentration of algae or krill with their mouths open. If so, the questions about how shadowdragons see prey in low light, why they never deviate the flight path while foraging, and how they are able to feed themselves in only 20 or 30 minutes would be answered." 3286. Endlein, T. Strohm, E.; Poethke, H.-J. (2002): Reproduction in a heterogeneous landscape: The consequences of habitat quality for reproduction and larval development in a damselfly. *Zoology (Jena)* 105 (Suppl. 5): 17. (in English). [Verbatim: "A landscape provides a heterogeneous mosaic of unsuitable and more or less suitable habitat patches. The differences in habitat quality affects survival and other fitness parameters of individuals and therefore oviposition of adults varies among habitats. In this study, we investigated variations in reproduction and larval development of the damselfly *Coenagrion puella* (Coenagrionidae: Odonata) in three neighbouring ponds (A, B, D in the following) in Bavaria/Germany. We examined (1) the density of egg laying ♀♀ as a measure of the number of eggs laid per pond, (2) the number of emerging adults, and (3) the size of the exuviae at each pond. The number of ovipositing ♀♀ was recorded by observation. Surprisingly, much more ♀♀ laid their eggs in D, the smallest of the three ponds compared to A and B. To count the number of emerging larvae a gauze fence was used as an emergence substrate that allowed standardised collection of exuviae. At D, 22 times more larvae emerged per meter shore line than from each of the large ponds. To compare the success of development in the different ponds we calculated the proportion of successfully developing larvae (estimated total number of eggs laid into a pond divided by the estimated total number of emerging adults). The smallest pond showed the highest estimated success, though the variance was high. The length of the tibia and praementum of a sample of ♂ exuviae was measured with high precision (1/1000 mm). Exuviae at pond D were significantly larger than exuviae at pond A and B over the whole emergence period. In conclusion, unexpectedly the smallest pond seems to offer the best conditions for larval development and survival for the damselflies and is preferred by ovipositing ♀♀. The causes for these small scale differences in habitat quality are not yet known." 3290. Freeland, J.R.; Conrad, K.F. (2002): Genetic similarity within and among populations of the Variable and Azure damelflies (*Coenagrion pulchellum* and *C. puella*). *Hydrobiologia* 479(1-3): 69-73. (in English). ["In the first half of this century, seven species of the damselfly genus *Coenagrion* regularly bred in Britain. Since that time, two of these species have become extinct, and three currently have highly restricted distributions. Of the remaining two species, *C. puella* is both common and abundant, but *C. pulchellum*, while more common than most *Coenagrion* species, is experiencing a national decline in Britain. The reasons for the decline of *C. pulchellum* are poorly understood, and therefore its future in Britain is difficult to predict. The aim of this study was to investigate genetic relationships among populations of *C. puella* and *C. pulchellum*. We obtained mitochondrial sequence data from 36 *C. puella* and *C. pulchellum* individuals collected from five different sites across central England. These revealed three haplotypes with high overall similarity. Hybridisation between *C. puella* and *C. pulchellum* was suggested by (1) The sharing of a haplotype between *C. puella* and *C. pulchellum*, and (2) The fact that morphological characters of sympatric *C. puella* and *C. pulchellum* populations are not always species-specific. More research is required before we can determine whether or not hybridisation is playing a role in the decline of *Coenagrion* species in the U.K." (Authors)] Address: Freeland, Joanna R., Dept of Biological Sciences, Open University, Walton Hall, Milton Keynes, Buckinghamshire, MK7 6AA, U.K.

3291. Fuhlendorf, S.D.; Englea, D.M.; Arnold, D.C.; Bidwell, T.G. (2002): Influence of herbicide application on forb and arthropod communities of North American tallgrass prairies. *Agriculture, Ecosystems and Environment* 92: 251-259. (in English). ["The primary approach used for reducing "weeds" in the native grasslands of the North American Great Plains is the application of a broadleaf-selective herbicide, which could have important implications to native plant and arthropod diversity. The objectives of this study were to identify the influence of herbicides on the forb and arthropod community composition, richness, and density, and determine relationships among the forb and arthropod communities in a tallgrass prairie of the North American Great Plains. In 1994, arthropod and forb communities were evaluated in eight treatment units and then a broadleaf-selective herbicide was applied to four of these units. Sampling of arthropod and forb communities were sampled under similar conditions in 1995 for post-treatment effects. These communities were highly variable across years regardless of treatment (herbicide and no herbicide). The herbicide treatment caused a reduction in overall forb dominance the year after treatment. Species richness increased from 1994-1995 in both treatments but the increase was less in the herbicide treatment. The herbicide application had no overall effect on forb species composition. The lack of effect of herbicide on the forb community composition coupled with a significant effect on species richness suggests that an important effect of herbicide application was a reduction of rare forbs. Analysis of these

tallgrass communities did not yield significant differences in arthropod abundance or richness between grasslands treated with a herbicide and grasslands not treated with a herbicide. The arthropod community was defined by extreme variability across years reflecting extreme fluctuations regardless of herbicide application." (Authors) "*Coenagrionidae*" are among the sampled taxa.] Address: Fuhlendorf, S.D.. Department of Plant and Soil Sciences, Oklahoma State University, Stillwater, OK 74078-6028, USA . 3293. Geppert, C.; Müller, J.; Xyländer, W.E.R. (2002): Marking of insects for finding them again at night. *Zoology (Jena)* 105 (Suppl. 5): 17. (in English). [Verbatim: "Marking of insects for the purpose of ecological studies has been used since 1920 (3). These methods only enable researchers to find insects again during daylight. Markings that allow to study the nocturnal behaviour of insects have been used and tested only occasionally due to the difficult procedures (1,2, 4). To investigate the roosting site behavior of odonates, we developed a marking method that can be used quickly on a large number of individuals without harming them. From the end of May until the end of August 2001 a total of 1907 damselflies, *Calopteryx splendens* Harris 1782 (1203 F and 704 E and 1659 dragonflies of different species (1067 F and 565 E were marked in the open cast mining area Berzdorf, about 5 km from Görnitz/Saxony. The following substances for marking were tested: 1) colored substances, applied to the thorax and/or the abdomen (Night pen, UHU neon glue, Pilot super color whit, Jenzi Tages-leuchtfarbe), 2) adhesive foils, applied to the thorax and/or the wings (glow-in-the-dark paper, reflecting foil), 3) substances for injection, injected into segments of the abdomen (Visible Implant Fluorescent Elastomer System). A 8 W/12 V UV fluorescent light (black light) was used for the detection of the insects at night. The following criteria were used to evaluate the marking procedures: good adhesion to the insect body, quick application, short drying period, low impairment of the insects, strong fluorescence at night as well as visibility during the day. These criteria were best met by the viscous paint "Jenzi Tages-leuchtfarbe". The outstanding feature of the paint was a maximum fluorescence at night of up to 4 meters distance. Marked insects showed no impairment in their behavior and could be observed during matings. With

the help of this method it was possible to find 125 out of 1,872 marked *C. splendens* again at night. While this only constitutes a recapture rate of 6.6%, it is high considering the extremely difficult circumstances of the nocturnal search. 1 Heller, K.-G. & O. von Helversen (1990): Survival of a phaneropterid bush-cricket studied by a new marking technique (Orthoptera: Phaneropteridae). *Entomol. Gener.* 15 (3): 203-208. 2 Hunger, H. & W. Röske (2001): Short range dispersal of the Southern Damselfly (*Coenagrion mercuriale*, Odonata) found experimentally using UV fluorescent ink. *Z. 3294. Glotzhober, R.C.; McShaffrey, D. (Eds) (2002): The dragonflies and damselflies of Ohio. Ohio Biological Survey Bulletin New Series Volume 14 Number 2: ix + 364 pp. - (in English). [This manual, based on Ohio, will work for Ontario to Tennessee, and from Missouri to New Jersey. In addition to the 162 Ohio species, 18 are found in neighboring states that are included in the keys (larvae: to the genus level, imagoes: to the species level). The book is organized in three parts resp. 17 chapters (I: Natural history, Collection and preservation of Odonata, History of Ohio odonatology, How to use the book; II: Photographing Odonata; III: Identification keys), and references, and six appendices. The book is lavishly illustrated, with 460 line drawings and wing scans. State maps show the distribution of all the species in Ohio at the county level, and the monographic descriptive accounts includes generous information on the natural history of each species. There are 88 color photos of adults; my impression is that some of them are reproduced too dark. In spite of this, they give me - unexperienced in North American Odonata - a significant impression of many species from Ohio. This is a heavy weighted, helpful, and very complete regional fauna with a lot of significant information on Odonata. (M. Schorr).] Address: \$40 plus shipping and handling (\$5) and Ohio Tax (\$2.30 if applicable). Send cheque to Ohio Biological Survey, Inc., P.O. Box 21370, Columbus, OH 43221-0370, USA

3295. Goffart, P. (2002): Compte-rendu de l'excursion sur l'Ourthe moyenne, de Marcourt à Hotton, due 26 juin 2002. *Gomphus* 18(1-2): 50-52. (in French with Dutch summary). [Belgium; 9 odonate species were recorded; main emphasis was given to *Oxygastra curtisii* which was recorded at six stretches of the river Ourthe. Foraging behaviour of a ♂, and oviposition of a ♀ are described. In addition, records of the stream dwelling species *Gomphus pulchellus*, *G. vulgatissimus*, and *Onychogomphus forcipatus* are briefly commented upon.] Address: Goffart, P., Unité d'Écologie et de Biogéographie, 5, Place Croix-du-Sud, B-1348 Louvain-la-Neuve, Belgium. E-mail: goffart@ecol.ucl.ac.be

3296. Gonseth, Y.; Monnerat, C. (in Zusammenarbeit mit: Rene Hoess, Christian Keim, Tiziano Maddalena, Alain Maibach, Claude Meier, Peter Weidmann, Hansruedi Wildermuth) (2002): Rote Liste der gefährdeten Libellen der Schweiz. Hrsg. Bundesamt für Umwelt, Wald und Landschaft, Bern, und Schweizer Zent-

rum für die Kartographie der Fauna, Neuenburg. BUWAL-Reihe Vollzug Umwelt: 46 pp. (in German, with Italian, French and English summaries). ["The Red List 2002 of the Swiss Dragonflies has been established applying the criteria and using the threatened species categories proposed by the IUCN (2001). The procedure used was adapted from GARDENFORS & al. (2001). Of the 72 native species of the Swiss fauna, 26 (36%) are threatened, while 12 (17%) are potentially endangered (NT). Out of the 72 species listed in the Red List, 2 are at present extinct in Switzerland (RE), 12 are nearly extinct (CR), 7 are endangered (EN) and 5 are vulnerable (VU). Species of marshes and of gravel banks along rivers are the most threatened. The Red List 2002 replaces the one published in 1994 (MAIBACH & MEIER in DUELLI 1994) and based on different criteria. This explains the rather important differences between the two, differences that essentially concern the proportion of species included in the categories of least threat. The comparison of the Red List 1994 and the Red List 2002 shows most convincingly the evident degradation of the situation where the most threatened species are concerned: two have not been observed for ten years and five others have suffered a severe decline." (Authors) The species included in the list are briefly discussed.] Address: BUWAL, Dokumentation, CH-3003 Bern, Schweiz.. E-Mail: docu@buwal.admin.ch. Bestellnummer VU 9011-D (gratis)

3297. Grand, D. (2002): La faune odonatologique de la fontaine vaclusienne du Lamalou (Hérault). *Martinia Hors Série* 4: 23-26. (in French). [The odonate fauna of the headwaters of the rivers Argens (n = 10) and Lez (n = 13) (taken from literature data) is compared with the fauna of the headwater of the Lamalou (n = 30). The habitat is described in detail and some species are discussed. *Coenagrion mercuriale* - a species of special conservation concern in Europe - is dominant. The emergence and sex-ratio of exuviae (♂♂: 49% of 233 exuviae) of *Boyeria irene* are outlined, and the oviposition behaviour of *Cordulegaster boltonii* is described likewise including a note on sex-ratio (♀: 58,2% of 337 collected exuviae).] Address: Grand, D., Impasse de la Voûte, F-69270 St. Romain-au-Mont d'or, France

3298. Grand, D. (2002): Sur la distribution de *Macromia splendens* (Pictet, 1843) en région méditerranéenne française: complément et synthèse. *Martinia Hors Série* 4: 17-22. (in French). [The paper documents efforts to trace *M. splendens* in the French mediterranean region including some localities published in the 19th and early 20th century. *M. splendens* was found only at the Ardèche whilst e.g. the species was lost for the type locality at the Lez near Montpellier. Co-occurring species are listed and some remarks on the behaviour and the habitat of *M. splendens* are made.] Address: Grand, D., Impasse de la Voûte, F-69270 St. Romain-au-Mont d'or, France

3299. Greff, N.; Manach, A.; Tillier, P. (2002): Atlas des Odonates de Bretagne. État d'avancement et éléments de réflexion. *Martinia, Hors Série* 4: 59-77. (in French with English summary). [Distribution maps of 55 odonate species for the region of Brittany in western France (Departments: Côtes-d'Armor, Finistère, Île-et-Vilaine, Loire-Atlantique, Morbihan) are presented.] Address: Greff, N., Ossée, F-38510 Sermerieu, France.

- 3300.** Grillet, E.M.; Legendre, P.; Borcard, D. (2002): Community structure of Neotropical wetland insects in Northern Venezuela. I. Temporal and environmental factors. *Arch. Hydrobiol.* 155(3): 413-436. (in English). ["The temporal distribution of aquatic insects in relation to habitat conditions was assessed in some northern Venezuelan Neotropical wetlands. The hypothesis that abiotic and biotic factors interacting in time may simultaneously explain the community structure of aquatic organisms was evaluated. Larval insects were sampled over a one-year period in five wetland types; 13 variables were quantified to describe each habitat. Partial redundancy analysis was used on insect abundance data to partition the variance into four components: a) pure environmental variation without seasonal effect, b) seasonal variation of environmental factors, c) pure temporal factors (months), and d) unexplained variation. Our results showed that pure and temporally-structured environmental factors (a + b) explained between 30 % and 58 % of the variation of insect abundances within wetlands, whereas pure temporal factors also significantly contributed 13 % -29% to variation in taxa abundance. Physical factors (rainfall and water depth), wetland trophic state (phytoplankton), and water chemistry (mainly CO₂ and alkalinity) were significantly associated to community structure variability. We hypothesize that the interplay of trophic conditions, related chemical conditions, wetland duration, and insect life history patterns, all of which are mediated by seasonal fluctuation in rainfall, could largely account for the temporal distribution of the insect taxa in these wetlands.."] (Authors) Odonata are treated at the family level.] Address: Grillet, Maria Eugenia, Laboratorio de Biología de Vectores. Instituto de Zoología Tropical. Facultad de Ciencias. Universidad Central de Venezuela, Apartado 47058, Caracas 1041-A, Venezuela. E-mail: mgrillet@strix.ciens.uvc.ve
- 3301.** Grillet, E.M.; Legendre, P.; Borcard, D. (2002): Community structure of Neotropical wetland insects in Northern Venezuela. II. Habitat type and environmental factors. *Arch. Hydrobiol.* 155(3): 437-453. (in English). ["This study examined the spatial distribution of wetland insects in relation to selected environmental variables in northeastern Venezuela. Sampling was carried out over two sampling periods (rainy and dry season) in seven wetland types (brackish and freshwater herbaceous swamps, mangrove swamps, freshwater ponds, clear-cut marsh forests, small irrigation canals, and swamp forests), covering three environmental gradients (salinity, aquatic vegetation type, and habitat permanence). Using the partial redundancy analysis, we determined that occurrence and abundance of insects was significantly ($P < 0.05$) accounted for by the relative contributions of pure environmental (29-34 %) and habitat type-related (12-15 %) variations among wetlands. Water chemistry (salinity), wetland trophic state (phytoplankton), habitat heterogeneity (aquatic vegetation type), and habitat physical features (depth and habitat permanence) were significantly associated to community structure. Insect richness was higher in the less saline, more vegetated, and less temporary wetlands. Our findings add to previous results suggesting that adversity, productivity, heterogeneity and permanence of the habitat represent important axes along which Neotropical wetland insect communities are organized." (Authors) Odonata are treated at the family level.] Address: Grillet, Maria Eugenia, Laboratorio de Biología de Vectores. Instituto de Zoología Tropical. Facultad de Ciencias. Universidad Central de Venezuela, Apartado 47058, Caracas 1041-A, Venezuela. E-mail: mgrillet@strix.ciens.uvc.ve
- 3302.** Hämäläinen, M. (2002): The species list of Thai dragonflies increases steadily - an update. *Malangpo* 19: 176-179. (in English). ["*Anaciaeschna martini* (Aeshnidae), *Macromia arachnomima* (Corduliidae) and *Nesoxenia lineata* (Libellulidae) are recorded from Thailand for the first time. Preliminary comments are presented on several other species new to Thailand, so far identified to genus level only. References to recent papers (published in 1999-2002), reporting additions to the Thai odonate fauna, are also given." (Author)] Address: Hämäläinen M., Dept Applied Zool., P.O.Box 27, FIN-00014 University of Helsinki, Finland; E-mail: matti.hamalainen@helsinki.fi
- 3303.** Harrison, S.S.C.; Harris, I.T. (2002): The effects of bankside management on chalk stream invertebrate communities. *Freshwater biology* 47: 2233-2245. (in English). ["1. Communities of aquatic macroinvertebrates and the terrestrial adult phases of aquatic insects were investigated from short stretches of English chalk streams with two different bankside vegetation types: simply structured grazed grass (grazed) and structurally complex herbaceous vegetation with scattered trees (ungrazed). Macroinvertebrates were sampled in spring, summer, autumn and winter 1996-97 from three aquatic habitats: mid-channel gravel, patches of the aquatic macrophyte *Ranunculus* and marginal emergent macrophytes. The terrestrial adult phases of aquatic insects were sampled in spring, summer and autumn from bankside vegetation. 2. Total macroinvertebrate abundance did not differ between stretches with different bankside vegetation. Taxon richness of mid-channel gravel was, however, significantly higher in ungrazed compared with grazed stretches and Shannon diversity (H') of mid-channel gravel and marginal vegetation was significantly higher in ungrazed compared with grazed stretches. Total abundance, taxon richness and H' of the terrestrial adult phases of aquatic insect were significantly higher from the bankside vegetation of ungrazed compared with grazed stretches. 3. Ordination of communities of aquatic macroinvertebrates and terrestrial adults demonstrated that individual families of both groups were generally more abundant in ungrazed stretches. Many more families were significantly associated with ungrazed stretches than with grazed stretches. 4. This investigation has shown that high structural diversity of bankside vegetation along lowland chalk streams is accompanied at the reach scale by increased diversity of both aquatic macroinvertebrates and the terrestrial adult phases of aquatic insects. The conservation potential of such streams may thus be lowered by management practices that result in the removal or simplification of bankside vegetation along extensive stream stretches." (Authors) *Calopteryx splendens* was significantly associated with ungrazed margins.] Address: Harrison, S., Department of Zoology and Animal Ecology, University College Cork, Lee Mailings, Prospect Row, Mardyke, Cork, U.K. E-mail: s.harrison@ucc.ie
- 3304.** Heitz, A. (2002): Habitat und Eiablage von *Coenagnum scitulum* (Gabel-Azurjungfer) an einem Fundort in Ost-Frankreich. *mercuriale* 2: 3-6. (in German). [In 2000, a population of *C. scitulum* near Passavant la Rochère, 38 km sw Epinal, Département Haute

Saone, France was traced. Habitat, oviposition behaviour, and identification features are outlined.] Address: Heitz, A., Moosweg 15, D-77749 Hohberg, Germany.

3305. Hoess, R. (2002): Odonata found in Chiang Mai, northwestern Thailand, in May 2002. *Malangpo* 19: 180-185. (in English). [A total of 67 odonate species was collected in Chiang Mai city and its surroundings in northwestern Thailand in May 2002. Additional 11 species were identified by sight records. Exuviae representing app. 20 species were found, but not yet identified. The localities are described, and the species are documented locality wise.] Address: Hoess, R., Normanenstr. 35, CH-3018 Bern, Switzerland

3314. Khunwiset, S.; Chanpaisaeng, J. (2002): A survey of Odonata adults and larvae in Thong Pha Phum district, Kanchanaburi province, Thailand. *Malangpo* 19: 192-194. (in English). [Verbatim: "Thong Pha Phum area in Kanchanaburi province in western Thailand has a high biodiversity, since it is within the precincts of 3 biogeographical regions (North, South and Central) joined together. It can be classified by ecological and biogeographical factors into 3 ecoregions i.e., Tenasserim-South Thailand Semievergreen Rain Forest, Kayah-Karen Montane Rain Forest and Chao Phraya Lowland Moist Deciduous Forest. Nearness of the Andaman Sea and surrounding mountain ranges provide plenty of rainfall in this region. The survey stu-

dying and collecting Odonata adults and larvae was carried out monthly during 6 months between March 2002-August 2002 at streams in the following 5 localities: Pongpuron, Ban Lampilok, Ban Prajammai, Ban Patsaduklang and Maenamnoi. A total of 44 species of adult Odonata belonging to 36 genera in 11 families were collected by using sweep net. Larvae were collected in March 2002. The material has been identified to the family level only. They represent 7 families: Chlorocyphidae, Euphaeidae, Lestidae, Coenagrionidae, Aeshnidae, Gomphidae and Libellulidae. The streams studied have high water level and currency, which moved larvae when the heavy rain occurred." Address: Jariya Chanpaisaeng and Sirikanya Khunwiset, Department of Entomology, Faculty of Agriculture, Kasetsart University, Bangken, Bangkok 10900, Thailand

3329. Matsuda, S.; Hiasa, M.; Sugihara, K.; Miyashita, M. (2002): Discovery of *Mortonagrion hirosei* from the mainland of Kyushu (Coenagrionidae). *Tombo* 44: 13-18. (in Japanese with English summary). [*M. hirosei* was discovered at two localities in 1998 for the first time from the main land of Kyushu, Japan. "Both sites are seaside marshes where reed bushes grow. We found andromorphic (homoeochromatic) ♀♀ at each locality. Although the distance between these two localities is only 2 km, the ratio of homoeochromatic ♀♀ differed greatly between them, being ca 1% at Mikoyama-shinden, and ca 50% at Otome-shinden. As the difference can be regarded as being genetically determined, the population of each local habitat should be conserved with no changes occurring in the type ratio." (Authors)] Address: not stated in English

3330. Mauersberger, R.; Bönsel, A.; Matthes, H. (2002): *Anax parthenope* in Seenlandschaften entlang der Pommerschen Eisrandlage in Nordost-Deutschland (Odonata: Aeshnidae). *Libellula* 21(3/4): 145-165. (in German, with English summary). ["From the lake-land-

scapes of Mecklenburg and northern Brandenburg, Germany, 146 localities of *A. parthenope* are listed, including 29 formerly published records. Completion of development was recorded at 28 waters. In one part of the area of investigation, the UNESCO-Biosphere Reserve 'Schorfheide-Chorin', *A. parthenope* is recorded from 15 % of the lakes. In the region, distribution and abundance of the species fluctuate considerably. Especially a cold winter with deficits in the supply of oxygen below the ice cover caused a strong temporary decline in population size. If these fluctuations are not taken into account, an increase of population size from 1989 until 2002 can be assumed. Stratified clear-water lakes with a constantly balanced oxygen supply in the littoral region constitute a persistent habitat in NE Germany. Moreover, *A. parthenope* is able to colonize for a limited time numerous lakes of all trophic levels and all sizes, as long as they are bordered by reed belts." (Authors)] Address: Mauersberger, R., Bahnhofstr. 24, D-17268 Templin, Germany. E-mail: FoerdervereinUeckermark.Seen@t-online.de

3331. Mauersberger, R.; Petzold, F. (2002): Seen als Habitate für *Onychogomphus forcipatus forcipatus* im Jungpleistozängebiet Nordost-Deutschlands (Odonata: Gomphidae). *Libellula* 21(3/4): 101-144. (in German, with English summary). [Brandenburg, Mecklenburg, Germany; *O. forcipatus* reproduces in 62 of 600 lakes, examined by the authors from 1989-2001. The habitat requirements can be described as follows: "volume (much) more than 30 000 m³ balanced oxygen proportion throughout the year without deficiency below ice cover often supplied by ground water in forested areas and without an outflow; accordingly with a high long-term water level amplitude low trophic state: total phosphorus mostly less than 25 mg/m³ surf zones with mineral sediment, usually at east or southeast banks exposed to wind inhabited parts of the shore are bare of vegetation or covered with thin reed belts up to 60 culms/m² (e.g. Meso-Phragmitetum). At the optimum habitat - mesotrophic ground-water lakes - *O. forcipatus* and *G. vulgatissimus* are the dominant anisopteran species." (Authors)] Address: Mauersberger, R., Bahnhofstr. 24, D-17268 Templin, Germany. E-mail: FoerdervereinUeckermark.Seen@t-online.de

3332. Merritt, R.W.; Cummins, K.W.; Berg, M.B.; Novak, J.A.; Higgins, M.J.; Wessell, K.J.; Lessard, J.L. (2002): Development and application of a macroinvertebrate functional-group approach in the bioassessment of remnant river oxbows in southwest Florida. *J. N. Am. benthol. Soc.* 21(2): 290-310. (in English). [Calcosahatchee River, SW Florida, USA; includes information on voltinism and larval habits for *Argia*, *Enallagma*, *Ischnura*, *Aphylla*, *Anax*, *Boyeria*, *Epithea*, *Brachymesia*, *Erythemis*, *Erythrodiplax*, *Miathyria*, *Pachydiplax*, and *Perithemis*.] Address: Merritt, R.W., Dept Ent., Fish. & Wildlife, Michigan St. Univ., East Lansing. MI 48824, USA

3333. Misof, B. (2002): Diversity of Anisoptera (Odonata): Inferring speciation processes from patterns of morphological diversity. *Zoology* 105: 355-365. (in English). ["With roughly 2500 described species Anisoptera are among the species-poor suborders within insects. [...] In this analysis phylogenetic research is integrated with comparative approaches to investigate possible explanations of differential speciation rates within this suborder. A short review of phylogenetic work based on

morphological characters is compared to published molecular Sistergroup comparisons are used to elucidate whether a) sexual selection, b) duration of life cycles, or c) differentiation in body size, have had a detectable effect on speciation rate. In all three analyses effects of distributional range and latitudinal distribution were controlled. These analyses suggest sexual selection promotes speciation and an increase in body size is positively correlated with speciation rate. The evolutionary significance of these results is discussed and experimental approaches that should advance our understanding of anisopteran diversity are suggested." (Author)] Address: Misof, B., Department of Entomology, Zoological Research Institute and Museum Alexander König, Adenauerallee 160, D-53113 Bonn, Germany E-mail: b.misof.zfmk@uni-bonn.de

3334. Moore, N.W. (2002): The dragonflies of a Cambridgeshire pond and its surroundings in 2001. *J. Br. Dragonfly Society* 18(1/2): 13-22. (in English). [The author visited a pond at Swavesey in Cambridgeshire on most days during the flying season (30 April to 15 November) of 2001. "As a result the records for that year are more complete than for any previous year since the pond was dug in 1983 (Moore, 1987) and thus seem worth recording. An additional reason for publishing the records for 2001 is that the flying season followed the wettest winter ever recorded and it was interesting to discover, whether this had had any noticeable effect on the dragonfly fauna of the pond. This paper provides a summary of my observations, which are related to other observations made on the pond since 1983 (Moore, 1987, 2002 and unpublished). The nature of the pond's dragonfly fauna is outlined, and the value and limitations of such studies is discussed." (Author)] Address: Moore N.W., The Farmhouse, 117 Boxworth End, Swavesey, Cambridge CB4 5RA, United Kingdom

3335. Moroz, M.; Maksimenkov, M.V.; Czachorowski, S.; Buczynski, P. (2002): Results of the investigation of aquatic insects (Insecta: Collembola, Ephemeroptera, Odonata, Trichoptera, Heteroptera, Coleoptera) of the Biosphere Reserve "Sporovskii". *Natural Resources 2* (National Academy of Sciences of Belarus. Ministry of Natural Resources and Environmental Protection. Scientific Edition): 88-94. (in Russian, with English summary) [Belorussia; 11 odonate taxa were traced, among them *Calopteryx splendens*, *Erythromma najas*, *Nehalennia speciosa*, *Epitheca bimaculata*, and *S. sanguineum*.] Address: Buczynski, P., Dept of Zool., Marie Curie-Sklodowska University, Akademicka 19, PL-20-033 Lublin, Poland. 3336. Mulnet, D. (2002): Développement larvaire de *Leucorrhinia dubia* dans deux biotopes de tourbières. *Martinia*, Hors Série 4: 85-90. (in French). [A population of *L. dubia* in a high bog near the Puy de Dôme, Auvergne, France, was surveyed for the development time in two different habitat types: one was covered densely with *Sphagnum* mosses, while the second type was characterised by a quite sparsely vegetation and a free water column. Larval developments in type 1 lasted 5 years, while in type 2 emergence took place after three years.] Address: Mulnet, D., 330 Rue Vercingétorix, F-63110 Beaumont, France

3337. Mulnet, D. (2002): Étude comparative de l'émergence de plusieurs espèces d'Odonates de tour-

bière. *Martinia*, Hors Série 4: 91-108. (in French). [Emergence patterns differed for 1986, 1990, and 1991 of *Leucorrhinia dubia*, *Pyrrhosoma nymphula*, *Libellula quadrimaculata*, *Somatochlora arctica*, *Lestes* sp., *Aeshna juncea*, and *A. cyanea* are presented and discussed in detail] Address: Mulnet, D., 330 Rue Vercingétorix, F-63110 Beaumont, France

3338. Mulnet, D. (2002): Utilisation pratique des modèle de capture recapture: application à une population de *Leucorrhinia dubia*. *Problèmes méthodologiques concrets et perspectives. Martinia* Hors Série 4: 39-48. (in French). [A study to estimate the size of a population of *L. dubia* in a bog near the Puy de Dôme, Auvergne, France is used to discuss in very detail the accuracy of population estimation methods.] Address: Mulnet, D., 330 Rue Vercingétorix, F-63110 Beaumont, France

3339. Murray, C. (2002): Dragonflies - ancient animals under threat. *Atropos* 17: 19-25. (in English). [This is a general account on factors threatening Odonata, including brief remarks on habitat destruction, pollution, inappropriate habitat management, alteration of site hydrology, and global climate change] Address: Murray, Charlotte, English Nature North Mercia team, Attingham park, Shrewsbury, SY4 4TW, UK

3340. Naraoka, H. (2002): Reproductive behaviour of *Lestes temporalis* Hanseman [sic] (Odonata, Lestidae). *Gekkan-Mushi* 381: 38-41. (in Japanese). [The oviposition of *Lestes temporalis* Selys 1883 at night and the egg deposition frequency in dependence of air-temperature are reported. A translation of the paper is published in *Digest of Japanese Odonatological Short Communications* 14.] Address: Naraoka, H., 36-71, Motoizumi, Fukunoda, Itayanagi-cho, Kitatsuguru-gun, Aomori Prefecture, 038-3661, Japan

3341. O'Brien, M. (2002): Highlights from the Great Lakes Odonata meeting, Higgins Lake MI, July 1-4, 2002. *Argia* 14(3): 6-9. (in English). [The dragonfly records of different trips are outlined; records of *Somatochlora hineana* and *Aeshna sitchensis* are of some interest.] Address: O'Brien, M., Insect Division, Museum of Zoology, University of Michigan, Ann Arbor, MI 48109-1079, USA. E-mail: mfobrien@umich.edu

3342. Orioux, G.; Laleure, J.-C. (2002): Les Odonates de la Loire et de l'Allier dans le département de la Nièvre. *Martinia*, Hors Série 4: 49-51. (in French). [Between 1983 and 1993 a total of 35 odonate species was recorded. The species composition of the channel, the branches, and standing waters within the floodplain are briefly compared] Address: Orioux, G., 25, rue Gambetta, F-58000 Nevers, France

3343. Orszaghova, Z.; Suplatova, M.; Orszagh, I. (2002): Changes in food composition of the tree sparrow (*Passer montanus*) nestlings. *Biologia* (Bratislava) 57(2): 251-259. ["Using the neck ring method we gathered two hundred and ninety-nine samples of food for nestlings of the tree sparrow (*Passer montanus*) at two sites (the Biological station and the alder forest in the National Nature Reserve Sur). The samples were divided into 12 animal (Gastropoda, Arachnida, Odonata, Mantodea, Saltatoria, Homoptera, Heteroptera, Megaloptera, Lepidoptera, Coleoptera, Formicoidea, Diptera) and 3 vegetable (grains of wheat, pea and fragments of various plant species) food groups. Soft-bodied Arachnida, beetle larvae and butterfly caterpillars predomina-

ted in the food of the youngest nestlings throughout the breeding season. With increasing age the food contained more hard-bodied arthropods and harder components of plants and their seeds. In May, 55 diet samples for the nestlings consisted mainly of butterfly caterpillars (25%), leaf hopper larvae (21%) and beetles (19%), the animal to vegetable component ratio (A:V) was 99.1%:0.9%. In June, spiders (20%) and beetles (20%) were the most frequent items in 108 samples. Three quarters of the beetles were larvae of *Spercheus emarginatus* (Spercheidae), and wheat grains represented 25%, the A:V ratio amounted to 69.7%:30.3%. In July one hundred and four food samples were collected, including praying mantes (*Mantis religiosa*) forming 28.5% of the material, Saltatoria 24.6%, and Arachnida 12%. The other diet groups were represented by lower percentages - the A:V ratio being 97.9%:2.1%. In August, 32 samples were collected, with beetles predominating in the food (28.8%), and a high proportion of *Sialis* sp. related larvae (26.4%) and Arachnida (24%). The A:V ratio was 99%:1%." (Author)]

3344. Parr, A. (2002): First and last dates. Dragonfly news 42: 17-18. (in English). [Compilation of early records of several odonate species in UK in spring 2002.] Address: Parr, A.J., 10 Orchard Way, Barrow, Bury St. Edmunds, Suffolk IP29 5BX, UK. E-mail: Adrian.parr@bbsrc.ac.uk

3345. Parr, A. (2002): The southern Skimmer *Orthetrum brunneum* (Fonscolombe). *Atropos* 16: 31-33. (in English). [The discovery of *O. brunneum* on Guernsey rises the possibility to discover the species on the mainland of Great Britain too. Therefore, some information on range expansion on the European continent, identification features, and the biology of the species are provided.] Address: Parr, A.J., 10 Orchard Way, Barrow, Bury St. Edmunds, Suffolk IP29 5BX, UK

3346. Paulson, D. (2002): New state records of *Enallagma* from Minnesota and New Hampshire. *Argia* 14(3): 12- (in English). [USA, *Enallagma clausum* (Minnesota, 30 May 1977); E. doubleday (New Hampshire, 7 July 1974)] Address: Paulson, D.R., Slater Museum, Univ. of Puget Sound, Tacoma, WA 98416, USA. E-mail: dpaulson@ups.edu

3347. Paulson, D. (2002): Philip S. Corbet, Honary member, the Dragonfly Society of the Americas. *Argia* 14(3): 5-6. (in English). [Dennis Paulson introduces into the recognition of Dr. Philip Corbet - "the preeminent odonatologist of our time" - as Honary Member of DSA, and briefly outlines some mile stones in his odonatological work. Special emphasize is given to the fact that Philip unhesitatingly shared his knowlege and ideas with many students and colleagues over the years, and to his inspiration to his colleagues.] Address: Paulson, D.R., Slater Museum, Univ. of Puget Sound, Tacoma, WA 98416, USA. E-mail: dpaulson@ups.edu

3348. Perrin, V. (2002): Highlights of the early season. Dragonfly News 42: 16- (in English). [Compilation of odonate records in 2002 with special emphasis on phenology from differend localities in UK] Address: not stated

3349. Petrulevicius, J.K.; Nel, A. (2002): A new libelluloid dragonfly from late Paleocene deposits in Argentina (Odonata: Italoansida). *Eur. J. Entomol.* 99: 485-489. (in English). ["A new genus and species of "libellu-

loid" dragonfly, *Jujusia maizgorda* gen. n., sp. n., of the clade Italoansida Bechly, 1996, from the late Paleocene, Maiz Gordo Formation, north-western Argentina, is described. Its phylogenetic relationships within the clade Cavilabiata Bechly, 1996 are discussed." (Authors)] Address: Petrulevicius, J.K., Departamento Cientifico Paleozoologia Invertebrados, Museo de La Plata. Paseo del Bosque, s/n. 1900 La Plata, and CONICET, Argentina. E-mail: levicius@mnhn.fr

3350. Petzold, F. (2002): Beobachtungen zum Verhalten von *Aeshna crenata* und *A. grandis* an einem Gewässer in Westsibirien (Odonata: Aeshnidae). *Libellula* 21(3/4): 79-100. (in German, with Russian and English summaries). [Sedelnikowo (56°57'N 75°16'E), NE part of administration district of Omsk, Russia; the behaviour of the coexisting species was observed from 1999-2001 at a man-made water body that was constructed as watering-place for cattle. "*A. grandis* was numerically the more dominant species; however, no interspecific interactions were noted. The reproductive activities of both species concentrated on a section of the water with highly structured vegetation and a great amount of dead wood. Both species preferred dead wood for oviposition but *A. crenata* used other kinds of dead and fresh plant material as well." ♀ refusal behaviour against ♂ mates is discribed. "Matings were not seen in *A. crenata* and only rarely in *A. grandis*. [...] More ♂♂ than ♀♀ of *A. crenata* and clearly more ♀♀ than ♂♂ of *A. grandis* were present at water. The activity of ♀ *A. crenata* lasted four hours per day and was significantly shorter than the eight hours spent by *A. grandis*." (Author)] Address: Petzold, F., Pappelallee 73, D-10437 Berlin, Germany. E-mail: falkpetzold@web.de

3351. Petzold, F.; Wildermuth, H. (2002): Massiver Wassermilbenbefall bei *Cordulia aenea* (Hydrachnida: Arrenurus; Odonata: Corduliidae). *Libellula* 21(3/4): 167 - 173. (in German, with English summary). ["A population of *C. aenea* heavily parasitized by larvae of *Arrenurus* sp. was found at a moorland lake in northern Germany in May 2002. The parasites attached in clusters, mainly to the pleural membrane ventrally on abdominal segments 7, 8 and 9. The findings are discussed in the frame of earlier observations on parasitized corduliids with corresponding interpretations that go back as far as to the 18th century." (Authors)] Address: Petzold, F., Pappelallee 73, D-10437 Berlin, Germany. E-mail: falkpetzold@web.de

3352. Pfeiffer, B. (2002): *Willamsonia fletcheri* encountered in Vermont. *Argia* 14(3): 10-11. (in English). [June 4, 2002, Washington County, Vermont, USA] Address: Pfeiffer, B., 113 Bartlett Rd, Plainfield VT, 05667, USA

3353. Purse, B. (2002): Conservation of the southern damselfly in Britain. *Biodiversity Technical Series* 1: 10 pp. (in English). [*Coenagrion mercuriale* is the only odonate species to have a national Species Action Plan (SAP) within the UK Biodiversity Action Plan. In the UK it is basically restricted to a few sites in Anglesey, West Wales, Gower, Devon, the New Forest, and the Itchen and Test valleys. Amongst these it occurs in three quite different habitat types: small lowland heathland streams, water-meadow ditches and calcareous fenland. In 1996/97 a Steering Group was set up to coordinate research and implement the SAP. A PhD was completed by Beth Purse, working under the direction

of Dr David Thompson at Liverpool University, to investigate the species on heathland sites. A second PhD study is now underway to investigate the ecology of the species in its other contrasting habitats: chalk stream, watermeadow and fen. The Environment Agency has recently published a superb illustrated booklet Conservation of the southern damselfly in Britain, R7D Leaflet W1-021/L, (contact 01793 860512 or publications@wrcplc.co.uk), which summarises Beth Purse's results. Other current research has involved collecting DNA samples from all known UK sites. Analysis should show what links, if any, exist between the somewhat discrete populations in their varying habitats.] Address: Environment Agency, Rio House, Waterside Drive, Aztec West, Almondsbury, Bristol BS32 4UD, UK.

3354. Quintana, A.T.; López, C.N. (2002): New locality records for Odonata in Pico Cristal National Park, Cuba. *Argia* 14(3): 15-16. (in English). [9 species were observed in 2001.] Address: Quintana, A.T., Univ. De Oriente, Santiago, Cuba

3355. Ring, S.; Kraus, F.B.; Schierwater, B.; Hadrys, H. (2002): Evolutionary ecology and genetic diversity measures in dragonflies. *Zoology (Jena)* 105 (Suppl. 5): 73. (in English). [Verbatim: "Dragonflies provide key model systems not only to study the evolution of mating systems (Fincke & Hadrys 2001, *EVOLUTION* 55: 762) but also to address the issue of how to define operational taxonomic units in conservation biology (conservation units). Field studies on dragonfly diversity and abundance in a variety of European, African, North and South American habitats have been combined with genetic diversity measures by means of multiple nuclear and mitochondrial DNA sequence markers (including ITS1, ITS2, C01, CO2, D-loop, ND1, 16S rDNA, and Hox genes) and neutral DNA markers (microsatellites, RAPDs). Information on both data sets helps to detect ecological and evolutionary effects on population networks and species assemblages, e.g. demographic patterns of habitat fragmentation, bottleneck effects and habitat shift processes. For example, within the European members of the riverine damselfly family Calopterygidae the identification of taxonomic units is very controversial and varies from 3 to 200 reproductive entities. Despite the high number of different phenotypes, sequence analyses of four DNA loci show very low genetic diversity within and between the proposed species/subspecies. This incongruence suggests recent speciation processes. Reconstruction of habitat preferences suggests that recent habitat shifts correlate with differences in the phenotype. In a second study on the keeled skimmer *Orthetrum coerulescens* the genetic consequences of a local bottleneck have been quantified. The latter revealed a significant number of private alleles for the largest population within a local network. These alleles were lost after the breeding site was dredged and a significant mode shift in allele frequencies (typical for a genetic bottleneck) took place. This demonstrates, that despite the fast recovery potential in terms of effective population (within 2 generations) and a network of smaller populations in the surrounding, a large self-perpetuating dragonfly population was affected by a cryptic loss of genetic diversity. We acknowledge support from the DFG and BMBF."] Address: Hadrys, H., Ecology and Evolution, ITZ, Tierärztliche Hochschule Hannover, 30559, Hannover, Germany. E-Mail: heike.hadrys@ecolevol.de

3356. Rosche, L. (2002): Dragonflies and damselflies of Northeast Ohio. *Cleveland Mus. Nat. Hist., Cleveland/OH*. ISBN 0-9717460-0-1. vii, 94 pp. (in English). [I assume, this book was planned as a guide directed to a public interested more generally in dragonflies, and to motivate it to get more and more interested in the Odonata. Larry Rosche documents the species that occur in a region that is - as J.B. Keiper states in his foreword - "fantastically rich with aquatic habitats. Fens, bogs, marshes, lakes, streams, springs and other wonderful ecosystems exist within an hour's drive of any northeastern Ohio city or town. In these areas, you can easily find a species-rich and abundant odonate fauna whose patrolling of territories, mating activities, predatory efforts and other behaviors will offer many rewarding observations. Use this guide and put names on those species you see." The book should also be useful elsewhere in the Great Lakes Region of USA and Canada, as most of the 124 species found in the scope of the book are found in Michigan, Indiana, Wisconsin, Minnesota, and Illinois as well as Ontario. The book is filled with lots of hints on identification, biology and habitat information; special emphasis is given to the phenology, and it is useful to get information on the regional rarity of the species. In general, the illustrations (most seem to be watercolor or color-pencil realized by three artists with different styles: Jacqueline Haley, Jennifer Brumfield and David Metcalf) depict the species well enough for identification. The digital images of the bluet reference guide on page 90 are very nice: The placement of all the bluets on one page is a great idea that enables the user to compare the species in one view. Some of the illustrations (Aeshnidae, Gomphidae) look digitally mounted using a morphological construction kit. It is hard to assess with the view of a European whether the illustrations fit to the reality. I think some of the artwork lacked detail in some cases, some of the perspectives seemed to distort terminal genitalia of the damselflies (way too big), some of the colors were too muted, or in the case of the *Argia* or *Hetaerina americana*, the bodies looked like pinned. Some of the paintings - especially the clubtails - lack in contrast and details. The wire-comb binding allows the pages to lie flat, which is great. However, the cover pages will be easily ripped or bent by repeated use in the field, so a plasticized cover is recommended. The book is attractive and reasonably priced, and I think it will deserve a spot on your shelf or in your backpack when travelling through NE Ohio. (M. Schorr)] Address: Publishers: Cleveland Mus. Nat. Hist., 1 Wade Oval, University Circle, Cleveland, OH 44106-1767, USA. Price: US \$ 18.95 net

3360. Stoverock, M.; Schierwater, B.; Soendergerath, E.; Braune, E.; Suhling, F.; Martens, A.; Richter, O.; Hadrys, H. (2002): Understanding the dynamics of biodiversity in African dragonflies: Genetic approaches. *Zoology (Jena)* 105 (Suppl. 5): 74. (in English). [Verbatim: "Present-day patterns of biodiversity among ecosystems have arisen over time through a variety of natural and anthropogenic factors. Understanding these factors may provide crucial insights into the effects of future environmental changes. One basic requirement here is to understand and follow population structures and dynamics, for which estimates of gene flow and genetic diversity become a sine qua non. We use molecular genetic data from the mitochondrial and nuclear genome to monitor the genetic composition of defined key species under various demographic and ecological settings. Four different DNA sequence markers allow the straightforward detection of taxonomic units at the population to genus level. Microsatellites offer insights into intrapopulation structures. The genetic data provide first insights into the genetic structure, viability and dispersal potential of natural populations which differ in habitat selection, abundance, life cycle parameters and dispersal behaviour. The combination of multiple genetic markers also provides information on different evolutionary time scales and therefore accounts for the historical dimension of changes in biodiversity. The data will be used in mathematical simulation studies that will model the dynamics of dragonfly biodiversity in African dragonflies. We acknowledge support from the BMBF (BIOLOG Africa #01LC0024).] Address: Suhling F., Zool. Inst., TU Braunschweig, Fasanenstr. 3, D-38092 Braunschweig, Germany. E-mail: f.suhling@tu-bs.d

3362. Tarboton, W.; Taboton, M. (2002): A fieldguide to the Dragonflies of South Africa. Private publication, 2002. 97 pages. ISBN 0-620-29887-1. 97 pp. (in English). ["This colourful little fieldguide treats all 90

species of Anisoptera found in the Republic of South Africa. Following a brief introduction to classification, behaviour and identification methods, the larger part of the book is devoted to species identification. Brief texts on occurrence and identification are accompanied with distribution maps and 34 colour plates. The latter are composed of scans of specimens, the majority of which is of very fresh individuals, showing the life colours. The layout of the plates is attractive and roomy, with on average 7 scans on each plate. Distinctive features are indicated, sometimes elucidated with simple line-drawings, and the scans are sufficiently clear for the user to compare and find additional characters himself. On average there are about 3 scans per species, e.g. a dorsal aspect of both sexes and a lateral aspect of one, allowing an impression of the variability. The book is augmented with 29 photographs of free-living dragonflies, including some of the most stunning pictures of African species ever published (e.g. *Anax tristis* ♀ in flight and ovipositing). With the wealth of illustrations, identification becomes surprisingly straightforward, and the user is helped further with simple pictorial keys to families and gomphid and libellulid genera. The accessible image-oriented concept of the book is highly innovative in a group where we are used either to complicated technical keys or photoguides using field photos, allowing only limited views of characters and variation. The example is definitely one to be followed, especially in the species-rich faunas of the tropics where the scans-approach is perhaps the only way to do justice both to the diversity of Odonata and the growing interest for them. It is to be hoped the authors are planning a similar book for the Zygoptera!" (K.D. Dijkstra, taken from Phaon 2003:01, 11 March 2003).] Address: The book can be ordered for 200 rand, which includes postage (approx. 23 euro/US dollar) from: Russel Friedman Books cc, P O Box 73, Halfway House 1685, SOUTH AFRICA; attention Shelley Tel 027 -11-702-2300; Fax 027-11-702-1403; Email: shelleyrh@mighty.co.za Website: vwww.rfbooks.co.za

3363. Versonnen, B.; Knijf, G. de; Vercruyse, W.; Verhaeghe, W.; Van Wichelen, T. (2002): Four observations and first successful reproduction of *Sympetrum meridionale* (Selys, 1841) in Belgium. *Gomphus* 18(1-2): 3-13. (in Dutch, with English and French summaries). ["After nearly a century of absence, *S. meridionale* was seen 3 times in 2000 and once in 2001. There was an observation at Rekem (Limburg) on 20/06/2000, one at Harchies (Hainaut) on 25/06/2000 and one at Zelzate (East-Flanders) also on 25/06/2000 and finally one at Stekene (East-Flanders) on 01/08/2001." The specimens "of 2000 were young: twice a young ♂ (Rekem and Zelzate) and one freshly emerged ♀ at Harchies. Especially this last observation proves that *S. meridionale* was able to reproduce successfully in Belgium. Very remarkable was the predation on a young ♂ at Zelzate by a domestic cat." (Authors)] Address: Knijf, G. de, Instituut voor Natuurbehoud, Kliniekstraat 25, B-1070 Brussel, Belgium. E-mail: geert.de.knijf@instnat.be

3364. Wasscher, M. (2002): Canal damselfly *Cercion lindenii* (Selys) - a species to look out for. *Atropos* 16: 62-63. (in English). [Some information on range extension on the European continent, identification features, and biology are provided, because the possibility exists to discover *C. lindenii* on the mainland of Great Britain in near future.] Address: Wasscher, M., Minstraat 15bis,

3365. Weihrauch, F. (2002): Ein Weibchen von *Enallagma cyathigerum* als Unterwasser-Prädator der Großen Weidenrindenlaus (Odonata: Coenagrionidae; Homoptera: Lachnidae). *Libellula* 21(3/4): 175-180. (in German, with English summary). ["A ♀ *E. cyathigerum* was observed feeding on larvae of *Tuberolachnus salignus* (Gmelin), on an accidentally submerged willow twig during a subsurface walk, possibly with the aim of oviposition. Seven or eight of the obviously soaked and half-drowned aphids were consumed within five minutes. This observation is discussed, and a list of other records from the literature of Homoptera as odonate prey is given. This is apparently the first published record of an imaginal dragonfly foraging under water." (Author)] Address: Weihrauch, F., Hengelerstr. 9, D-80637 München, Germany. E-mail: Florian.Weihrauch@t-online.de

3366. Weihrauch, F. (2002): *Enallagma* versus *Vespa*. *mercuriale* 2: 17-18. (in German). [Detailed description of the preying of a *Vespa* sp. upon *Enallagma cyathigerum*. Special emphasis is given to the habit of the *Vespa* to secure the damselfly from the surface of the water.] Address: Weihrauch, F., Hengelerstr. 9, D-80637 München, Germany. E-mail: Florian.Weihrauch@lbp.bayern.de

3367. Westermann, K. (2002): Die Abundanz schlüpfender Libellen in einem südbadischen Altrheingebiet. *Naturschutz südl. Oberrhein* 3: 215-244. (in German, with English summary). ["Within six years of research 192 000 exuviae of dragonflies were collected along two sections of side streams (2.6 km long, 10 to 50 m wide) of the river Rhine near the village of Weisweil (County Emmendingen; Baden-Württemberg, SW Germany). Thus the successful reproduction of 34 dragonfly species could be proven. The occurrence of all species is shown in classes of abundance, spanning six orders of magnitude. 1 The most common species is *Cercion lindenii* with a maximum abundance of 15 000 emerged imagines along 50 m of the stream. The species was found in perfect habitat in a 32 to 40 m wide section of the river, where eutrophic water is running with a regular speed of 0.1 to 0.2 m/s. Here also *Platycnemis pennipes*, *Ischnura elegans* and other species reach high abundance. Optimal habitat for *Pyrrosoma nymphula* exists along shallow sections, where there is no fish. Other species that reach their highest classes of abundance when emerging in shallow sections, are *Aeshna cyanea*, *Brachytron pratense*, *Libellula fulva*, *Sympetrum vulgatum* and *S. sanguineum*. *Gomphus pulchellus* is widely distributed in the study area and along other side streams, and reaches classes of abundance that can presumably exceed those of artificial lakes in gravel pits. Along old side streams *Calopteryx splendens*, *Chalcolestes viridis*, *Platycnemis pennipes*, *P. nymphula*, *Coenagrion puella*, *C. lindenii*, *Erythromma najas*, *Ischnura elegans*, *G. pulchellus*, *G. vulgatissimus*, *B. pratense*, *L. fulva*, and *S. striolatum* probably find optimal habitat in the southern Upper Rhine plains. Due to the large number of waters more species have also huge populations. The dragonfly communities of various stream sections can differ enormously. The biggest difference was found between a slowly and steadily running old side stream and the upper section of a cool, wide source; river ("Gießen") with summer

temperatures of 14 to 17°C. While *P. nymphula*, *C. viridis*, and *Coenagrion puella* have large populations at the Gießen every year, *P. pennipes*, *C. lindenii*, *I. elegans* and other species almost entirely fail. Results obtained in this study show the current status of dragonflies in typical waters called "Altrhein" (old) side stream and "Gießen" (source river). Changes and losses in the dragonfly communities might occur as soon as the "Integrated Rhine Program" (a programme to manage high floods of the river Rhine) will come into effect." (Author)] Address: Westermann, K., Buchenweg 2, D-79365 Rheinhausen, Germany. E-mail: fosor@t-online.de

3368. Westermann, K. (2002): Schlupf einer *Gomphus vulgatissimus* im August. *mercuriale* 2: 20-21. (in German). [Documentation of a late seasonal record (9. August 2002) of *G. vulgatissimus* from an oxbow of River Rhine near Weisweil, Baden-Württemberg, Germany.] Address: Westermann, K.; Buchenweg 2, D-79365 Rheinhausen, Germany. E-mail: fosor@t-online.de

3369. Westermann, K. (2002): Zur Phänologie der Emergenz bei der Gebänderten Prachtlibelle (*Calopteryx splendens*) an südbadischen Altrheinen. *Naturschutz am südl. Oberrhein* 3: 193-200. (in German, with English summary). [Along old side streams of the river Rhine in South Baden the emergence of *C. splendens* lasts until late August or the first days of September and thus at least six weeks longer than according to data given in the literature for the Federal state of Baden-Württemberg, Germany. High floods and rainfall shortly before emergence probably lead to considerable temporal shifts in the emergence and losses in the population.] Address: Westermann, K., Buchenweg 2, D-79365 Rheinhausen, Germany. E-mail: fosor@t-online.de

3370. Woodward, G.; Hildrew, A.G. (2002): Body-size determinants of niche overlap and intraguild predation within a complex food web. *Journal of Animal Ecology* 71: 1063-1074. (in English). ["1. Body-size may be an important feature of the structure of food webs. Detailed food web data are however scarce, particularly those including ontogenetic dietary shifts within species. We examined the predator guild in a well characterized food web, that of Broadstone Stream (UK), to assess the importance of body-size within and among species in relation to intraguild predation and niche overlap. 2. In agreement with recent food web theory, mutual predation and cannibalism were frequent and occurred in many pairwise permutations. This intraguild predation was strongly asymmetric, being determined by relative body-size within and among species, and seasonal 'ontogenetic reversals' in trophic status arose when generations overlapped. 3. Predator size determined dietary overlap, with ontogenetic shifts often outweighing taxonomic differences. Small predators had the narrowest diets, regardless of species, and were limited to feeding on a restricted subset of the total prey size-spectrum. Niche overlap decreased as pairwise differences in body-size increased among and within species. Overlap in diet also tracked seasonal changes in resource availability, being highest in summer, when prey were abundant and small, and declining progressively over time, as prey became scarcer and/or larger. The small predators also became more detritivorous as prey abundance declined and the larger prey species attained size-refugia. 4. The body-size

constraints driving feeding relationships within the predator guild, in terms of both resource partitioning and intraguild predation, lend support to recent niche models of food web structure (Warren 1996; Williams & Martinez 2000). The highly interconnected food web of Broadstone Stream appeared to be structured by relatively simple rules, with seasonal and ontogenetic shifts in the size-spectrum accounting for most of the changes in predator diet and trophic position. Encounter rate in time (prey and predator mobility) and space (micro-habitat use) and foraging mode also influenced prey vulnerability and niche overlap, but were secondary to the effect of body-size." (Authors) Key predator is *Cordulegaster boltonii*; thus, some focus of the study lies on this species.] Address: Woodward, G., School of Biological Sciences, Queen Mary University of London, Mile End Road, London, E1 4NS, UK. E-mail: Guy-Woodward@hotmail.com

3371. Woodward, G.; Hildrew, A.G. (2002): Differential vulnerability of prey to an invading top predator: integrating field surveys and laboratory experiments. *Ecological Entomology* 27: 732-744. (in English). ["1. A new top predator, the dragonfly *Cordulegaster boltonii*, invaded Broadstone Stream (U.K.) in the mid-1990s. This provided a rare opportunity to assess the impact of a new, large carnivore on a community that has been studied since the 1970s and has one of the most detailed food webs yet published. The vulnerability of the resident species to the invader was assessed by integrating experiments, which examined discrete stages in the predation sequence, with empirical survey data. 2. Although the new predator preyed on nearly every macro-invertebrate in the food web, vulnerability varied considerably among prey species. Size-related handling constraints initially set the predator's diet, resulting in strong ontogenetic shifts, with progressively larger prey being added while small prey were retained in the diet, as predators grew. Within the size range of vulnerable prey, encounter rate limited the strength of predation, with mobile, epibenthic species being most at risk. Contrary to most studies of interactions between freshwater predators (usually stoneflies) and prey (usually mayflies), the new predator did not elicit avoidance responses from its prey, probably because it combined a highly cryptic feeding posture with an extremely rapid attack response. 3. The invader exploited its prey heavily in experiments, even at prey densities orders of magnitude above ambient. In the field, electivity reflected prey availability, as determined by mobility and microhabitat use, rather than prey abundance or active predator choice. Consequently, the invader had skewed effects within the prey assemblage, with sedentary, interstitial species being far less vulnerable than more active, epibenthic species, some of which, including a previous top predator, have declined markedly since the invasion. 4. By examining the predation sequence in detail and integrating surveys with experiments, species traits and system characteristics that determine the strength of trophic interactions may be identified, and their potential importance in natural food webs assessed. In so doing, greater insight can be gained into which species (and systems) will be most vulnerable to invading or exotic predators, an imperative in both pure and applied ecology." 3373. Xylander, W.E.R.; Richter, M. (2002): Erstnachweis der Pokalazurjungfer *Cercion lindenii* (Selys, 1840) (Odonata, Coenagrionidae) für den Freistaat Sachsen. *Abh. Ber. Naturkundemus. 74(2)*: 273-282. (in German with English summary). [Germany; "*C. lindenii* was recorded for the first time in Saxony in July 2002 at the Knappensee about 15 km south of the Brandenburg border. The Knappensee was formed by lignite mining and flooded about 1945. The lake exhibits a rich submerged vegetation dominated by *Myriophyllum spicatum* and a fragmented peripheral reed vegetation, especially at those sites where *C. lindenii* was found; this corresponds with the habitat characteristics from other localities. The adult density was low compared to other sites in Germany. Morphometric data show that the population from the Knappensee corresponds to those of the eastern population in Germany (from Brandenburg) in that the specimens are larger than individuals from western populations. However, the Saxon specimens even exceeded the data of Brandenburg *C. lindenii* regarding all morphometric parameters." (Authors)] Address: Xylander, Dr. W., Staatliches Museum für Naturkunde Görlitz, PF 300154, D-02806 Görlitz, Germany. E-mail: Naturmuseum.GR.Dr.Xylander@t-online.de

3375. Yourth, C.P.; Forbes, M.R.; Baker, R.L. (2002): Sex differences in melanotic encapsulation responses (immunocompetence) in the damselfly *Lestes forcipatus* Rambur. *Can. J. Zool.* 80(9): 1578-1583. (in English, with French summary). ["A few studies have shown that ♂ and ♀ invertebrates differ in immunity and that these differences appear related to differences in sexual dimorphism and gender differences in life histories. Melanotic encapsulation of foreign objects in insects is one form of immunity. *L. forcipatus* is moderately sexually dimorphic, and much is known about patterns of mass gain in congeners relating to differences in life history between ♂♂ and ♀♀. In this study, ♀♀ were more immunoresponsive than ♂♂ under controlled temperatures, following emergence, and at a time when parasitic mites were challenging these hosts. However, ♂♂ and ♀♀ that overlapped in mass at emergence did not differ in their immune responses. ♂♂ in better condition at emergence were more immunoresponsive than lighter ♂♂, but this relation was not found in ♀♀. Sex differences in immune expression

may have implications for how ♀♀ versus ♂♂ are able to deal with challenges from parasites, under varying environmental conditions.] Address: Baker, R.L., Dept Zoo., Erindale Coll., Univ. Toronto, Mississauga, ON, L6L 2C6. Canada. e-mail: rbaker@credit.erin.utoronto.ca

3376. Abro, A. (2003): The composition of sperm bundles in *Aeshna juncea* (L.) (Anisoptera: Aeshnidae). *Odonatologica* 32(2): 153-157. (in English). [Using light and electron microscopy, sperm packing has been studied in the large sperm bundles of *A. juncea*. "Each large bundle is built up of variously-sized smaller bundles which probably reflects the intracyst formation procedure. It is proposed that initially there is a gathering of immature sperm cells into small bundles at several sites within the testicular cyst, and secondly all sperm heads are bundled together. This construction of subunits may be of importance to bundle break-down and release of individual sperm cells after transfer to the ♀ reproductive organs." (Author)] Address: Abro, A., Department of Anatomy, University of Bergen, Arstadveien 19, N-5009 Bergen, Norway

3377. Baird, J.M.; May, M.L. (2003): Fights at the dinner table: Agonistic behavior in *Pachydiplax longipennis* (Odonata: Libellulidae) at feeding sites. *Journal of Insect Behavior* 6(2): 189-216. (in English) ["Aggressive behavior of *Pachydiplax longipennis* during foraging was quantified by observing focal individuals on arrays of artificial perches. *Pachydiplax* apparently aggressively defend, for up to several hours at a time, one or a few feeding perches. Seventeen percent of all behaviors included agonistic actions, e.g., chasing or physical contact. The frequency of interactions was correlated positively with ambient temperature, solar radiation, prey density, and density of other dragonflies. Both sexes initiated and responded to intra- and interspecific aggression; intraspecific interactions were more intense, however. Males had significantly higher interaction rates and fighting success than females, and intraspecific male-male contests were particularly intense. When prey were visibly localized, contest winners commonly gained perches closer to the prey swarm, and aggressive behavior was apparently correlated with feeding opportunity. Despite the frequency of aggression, these dragonflies allocated only about 19 s, on average, to agonistic behavior during 30-min observation periods. This and other costs appear small compared to foraging benefits of occupying a favorable perch, although at a very high interaction intensity high energy costs and lower intake reduce the net energy gain." (Authors) Address: May, M.L., Dept Entom., New Jersey Agricultural Experiment Station, Cook College, Rutgers Univ., New Brunswick, NJ 08901-8524, USA. E-mail: may@aesop.rutgers.edu

(2003): Ein weiteres Vorkommen von *Aeshna subarctica elisabethae* (Walker, 1908) [sic] in Sachsen (Odonata, Aeshnidae) und Hinweise zur Libellenfauna der Natura-2000-Lebensraume 7110, 7140 und 7150. *Entomologische Nachrichten und Berichte* 47(1): 27-30. (in German with English summary) [Adults and exuviae of *A. subarctica elisabethae* Djakonov, 1922 were found in a transition mire in the south of the "Muskauer Heide" (Germany, Saxony) near the Polish border in 2001 and 2002. The habitats are described, co-occurring Odonata (including *Ophiogomphus cecilia*, *Somatochlora arctica*, *Leucorrhinia pectoralis*, *L. rubicunda*, and *Sympetrum depressiusculum*), and a list

of the known Saxonian localities of *A. subarctica* is given. The potential as bioindicators of the odonate fauna of the NATURA-2000-habitats 7110 (bogs), 7140 (transition mires), and 7150 (Rhynchosporion) is discussed.] Address: Brockhaus, T., An der Morgensonne 5, D-09387 Jahnsdorf, Germany. E-mail: T.Brockhaus@t-online.de

3386. Brooks, S. (2003): Dragonflies. life series. ISBN 0 565 09189 8. 96 pp. (in English). [In general, I think, we are living in times with overboarding information. The same goes for odonatology. Browsing OAS, one will find more and more papers intensifying the study of details on many subjects of odonatology. That's science, and it is necessary to do so. On the other hand, one needs time to handle all these details. The outstanding book of Philip Corbet helped to do so in a very significant part of odonatology, but it is a heavy weight in any sense. Steve Brooks explicitly refers to Corbet's book, and to Jill Silsby's fine book introducing odonate species diversity. In his new book "Dragonflies", S. Brooks compiles the essentials of current knowledge in odonatology on 96 pages. He directs precise information on a reader more generally interested in dragonflies. "Most of us are aware of dragonflies and damselflies. Their aerial agility and vivid colours are evocative of the long, hot days of summer, of shimmering lakes and dappled shade by trickling streams. But fewer people will have looked beyond the flash of blue, red, green or yellow to consider what each dragonfly is doing. This book takes you into the world of these fascinating insects and introduces you to their complex lifestyles - from the ferocious larval stages, lurking amongst plants and debris in lakes and rivers, to the breathtaking adults swooping after prey or fighting rivals to defend their territories." All information are organised in brief chapters. This also helps the advanced odonatologist to update his knowledge, and it is done in a language easy to read. The book is furnished with brilliant photographs. If one intends to motivate people's interest in dragonflies by a book, one should take Steve Brook's book. It is a really excellent book, and moderate in price (app. 15,- Euro). Of course, it should not be missing from your own odonatological library. (M. Schorr)] Address: The Natural History Museum Publishing, Cromwell Road, London, SW7 5BD, United Kingdom

3393. Clarke, D. (2003): Blue Southern Hawker spotted. *Dragonfly news* 43: 35- [Aeshna cyanea; "I had almost forgotten about Mike Averill's appeal [...] when on 26 October I found myself watching a hawker quartering a forest ride in the Eden valley, Cumbria, in low mid-day sunshine. Fortunately, it settled to bask on low vegetation and I was able to approach undetected. The size and shape of the (yellow) dorsal patches on its thorax showed it to be a ♀ Southern Hawker. However, it was a very unusual one: all its dorsal abdominal markings were a clear blue, when this colour should have been restricted to the last segments! The sides of the thorax were the usual greenish yellow. I have not seen another like it before or since." (Author)] Address: David Clarke, david.clarke19@virgin.net

- 3394.** Clarke, D. (2003): Cumbria produces the goods! Dragonfly news 43: 35. (in English). ["[...] (Aeshna mixta) were duly seen in September (in the best weather of the season!), and in at least three different localities. At one site in the Lindale area the species was evidently in some numbers, and mating was seen. It also seems likely that the remaining sectors of the Lancaster-Kendal canal may be one of the routes for this dragonfly's northward movements. My note had also mentioned four other species as 'desirables', at least two of which were reported: singles of Emperor and Broad-bodied Chaser were noted (in August), again in this southern extremity of the county. [...]"] (Author)] Address: not stated
- 3395.** Clausnitzer, V. (2003): Dragonfly communities in coastal habitats of Kenya: indication of biotope quality and the need of conservation measures. Biodiversity and Conservation 12(2): 333-356. (in English). ["This study highlights the species diversity of Odonata from coastal forests in southern Kenya, identifying indicator species for certain habitat types and emphasising the importance of conserving the last remaining coastal forest areas. A total of 78 species were recorded from coastal habitats in southern Kenya in this study; five species for the first time in eastern Africa. Dragonfly communities relative to different habitat types from indigenous forest to cultivated landscapes are described and compared. The forest species are often confined to coastal forests of East Africa. They are stenotopic and highly sensitive to disturbance. With increasing habitat disturbance the species richness increases at first, but most of the colonisers are eurytopic species that are common and widely distributed in Africa. The species assemblages between different habitat types in the disturbed landscape are more or less the same; the beta-diversity is much lower than in different habitat types of the natural coastal landscape. In the end, management implications are briefly discussed."] (Author)] Address: Clausnitzer, Viola, Liebenauer Str. 180, D-06110 Halle/Saale, Germany. E-mail: violacl@gmx.de

- 3413.** Hornung, J.P.; Rice, C.L. (2003): Odonata and wetland quality in southern Alberta, Canada: a preliminary study. *Odonatologica* 32(2): 119-129. (in English). [The study was realised in Brooks, from May until Sept. 1999. "Sixteen study sites were each visited 7 times to survey adult dragonflies and aquatic macroinvertebrates, record environmental parameters, collect water samples, record vegetative characteristics, and assess beef cattle grazing influences. 25 odonate species were

recorded, of which *Ischnura verticalis* is new to Alberta. A significant negative correlation was detected between cattle presence (measured as percent stems grazed surrounding the wetland) and odonate species richness ($p = 0.022$; $r^2 = 0.322$), teneral species richness ($p = 0.018$; $r^2 = 0.337$), and the Shannon-Weiner diversity indices ($p = 0.060$; $r^2 = 0.230$) of the study sites. In addition, vegetation species richness and odonate species richness show a positive correlation ($p = 0.066$; $r^2 = 0.221$). A logistic regression establishes that the absence of *Coenagrion angulatum*, *Enallagma ebrium*, and *Aeshna interrupta* is associated with high cattle impacts, or low vegetation species richness. This study outlines the effect that cattle can have on wetland odonate species diversity and recommends that measures are taken to protect wetlands, while offering an incentive and reasonable cost/benefit ratio to both rangeland and wetland managers." 3418. Kamimura, Y. (2003): Effects of repeated mating and polyandry on the fecundity, fertility and maternal behaviour of ♀ earwigs, *Euborellia plebeja*. *Animal Behaviour* 65: 205-214. (in English). [I examined mul-

tiple mating and its function in ♀ earwigs, *Euborellia plebeja* (Dermaptera: Ani-solabididae). Like other earwigs, ♀♀ of this species care for their eggs and intermittently lay eggs in clutches (iteroparity). Analysis of two polymorphic allozyme loci revealed that wild-caught adult ♀♀ laid clutches with low within-brood genetic relatedness (0.210), indicating that ♀♀ were promiscuous under natural conditions. Rearing experiments in the laboratory revealed that: (1) repeated mating with a single ♂ increased ♀ fecundity (number of clutches laid) and hence the number of hatchlings produced; (2) estimated sperm number was positively correlated with hatchability; (3) when frequency of mating was controlled, polyandry enhanced hatchability, although this effect was not statistically significant; (4) duration of maternal care varied for clutches with low hatchability, and -sometimes exceeded the mean interclutch interval. Thus, although a possible benefit of polyandry is suggested, the greater beneficial effect of repeated mating on ♀ fecundity can explain polyandrous mating in this species. Because ♀ earwigs invest considerable effort in brooding their clutches, it may be adaptive to suppress oviposition unless stored sperm ensures high fertility." (Author) The results are discussed stressing sperm removal behaviour of Odonata.] Address: Kamimura, Y., Laboratory of Animal Ecology, Dept of Biol., Tokyo Metropolitan Univ., Minamiosawa 1-1, Hachioji, Tokyo 192-0397, Japan. 3424. Maezono, Y.; Miyashita, T. (2003): Community-level impacts induced by introduced largemouth bass and bluegill in farm ponds in Japan. *Biological Conservation* 109: 111-121. (in English). ["Largemouth bass *Micropterus salmoides* and bluegill *Lepomis macrochirus* have been introduced into many countries and have become cosmopolitan exotic species. However, only a few studies show their impact on introduced communities. To investigate their impact, we performed natural snapshot experiments in 15 farm ponds in Saitama prefecture, eastern Japan. We selected 10 and 5 small ponds in similar environmental conditions, but with and without exotics, respectively. The numbers of fish, crustaceans, and nymphal odonates were smaller in ponds where exotics were found and some species were considered to be locally extinct in several ponds. On the other hand, the numbers of benthic organisms, i.e. tadpoles, chironomids, chaoborids, and Oligochaeta

were more abundant in ponds with exotics. These two groups of organisms were separated clearly on the first axis of DCA, which indicates that this difference was mainly induced by bass predation. This result suggests a trophic cascade in which top-down effects induced by exotics propagated to fish, crustaceans, and nymphal odonates directly and to some benthic organisms indirectly. Therefore, when one is to conserve native organisms, attention should be paid not only to direct negative effects, but also to indirect effects propagating to various trophic levels. Because farm ponds are typical Japanese small lentic systems having rich biodiversities and bass and bluegill have been shown to change farm pond communities widely, conservational treatments including eradication of exotic fish should be conducted immediately." 3426. Manolis, T. (2003): *Dragonflies and Damselflies of California*. California Natural History Guides 72 (ISBN 0-520-23567-3). 201 pp. (in English). [A field guide has to introduce its subject to the reader. Thus, adult dragonfly anatomy, behaviour (feeding, antipredator, and reproduction behaviour, thermoregulation, dispersal), life cycles and larvae of dragonflies, family and subfamily key to dragonfly larvae, distribution (including a brief overview into Californian geographic regions), watching and identifying of dragonflies, taxonomy and nomenclature, "About the Maps", and family and subfamily key to adult dragonflies form the basement of this field guide on the first 36 pages. Species accounts refer to 108 odonate species known to occur in California (pages 39 -179): In a monographic style, each species is described in detail and compared with similar species. Its behaviour is briefly outlined, the habitat described, and the flight season given. In addition, the distribution is outlined in detail. A checklist of Californian Odonata, species of hypothetical occurrence, a glossary, references, and an index complete the book. The heart of the book are 40 plates of a breathtaking quality. They slightly resemble Dan Powell's plates in his book "Guide to the dragonflies of Great Britain", but they seem to be more precise in a scientific sense. Each species is illustrated, and details necessary to separate it from similar species are added on the plates. This book is a further addition to the (in most cases) excellent books on the North American Odonata currently published. My personal impression is, that it will be a precise and reliable tool to identify the Californian Odonata. I am fascinated from the artwork of Tim Manolis, and I can't stop thinking that the plates of the book should exist in an enlarged version for study rooms. My personal opinion is that Tim Manolis talent urgently should be used to prepare a new edition of Sid Dunkle's excellent book (*Dragonflies through binoculars*), which was disappointing in terms of the stamp like photo-

graphic illustrations. The book on Californian Odonata is priced 17,- US Dollar; this seems to me extremely good value compared with the quality of the book. (M. Schorr) Address: University of California Press, Publicity Dept, 2120 Bekeley Way, Berkeley CA 94720, USA

3427. Mauffray, B. (2003): Georgia summary. *Argia* 14(4): 5- (in English). [Status report on odonatological activities in Georgia, USA. The contribution include addresses of three web sites, and a note on the discovery of *Gomphus adelphus* cf.] Address: Mauffray, B., 4525 N.W. 53rd Lane., Gainesville, FL 32653, USA. 3428. Moore, J. (2003): Norman Winfried Moore. *Odonatologica* 32(1): 9-18. (in English). [A biography of Dr N.W.Moore (born 24 Feb. 1923) emphasize on matters concerning the study of Odonata and nature conservational activities. His bibliography (1939-2002) comprises of app. 135 odonatological titles, but ca 45 papers on pesticides and environment are omitted.] Address: Moore, J., Department of Zoology, University of Cambridge, Downing Street. Cambridge, CB2 3EJ, United Kingdom

3429. Müller, Z.; Jakob, T.; Toth, A.; Devai, G.; Szalassy, N.; Kiss, B.; Horvath, R. (2003): Effect of sports fisherman activities on dragonfly assemblages on a Hungarian river floodplain. *Biodiversity and Conservation* 12(1): 167-179. (in English). ["We studied the dragonfly fauna along a 15 km stretch of the floodplain of the regulated, first-order river Tisza, Hungary. Data on captured and observed adults, larvae and exuvia were recorded. Observations were made from May to October 1998 and 1999 on 34 species, which is 52% of the Hungarian fauna. Classification on the basis of faunistic similarity revealed that habitat-level differences, associated with various degrees of physical anthropogenic impact on bank vegetation, can exceed variation among the water bodies of different types (backwater, pond, marsh, canal, river). The richest sites were dominated by structurally diverse macrophyte vegetation, while flowing waters (river and canal) were poorest in species. Odonata were found to be reliable indicators of small-scale habitat patterns, reflecting vegetation differences even within single water bodies where the sampling spots were arranged just a few hundred metres apart. Along a gradient of utilisation intensity, the species number of Odonata assemblages and the summed relative abundance of the five rarest species of the study area decreased linearly with increasing fragmentation of the marginal vegetation. Sports fisherman activities, implying disruption of the littoral marsh zone by establishment of clearings and excessive trampling of the banks, can also be monitored by dragonfly faunistic investigations. Our results demonstrate that conservation of these varied floodplain water bodies requires the control of sports fishing activity, suggesting that (i) to maintain the representative odonate fauna of the water bodies, some non-fragmented shores must be provided; and (ii) permanent fishing stands should not exceed 8 m mean width and should be separated by at least 12 m of intact riparian sections." 3430. Muzlanov, Yu. A. (2003): The pattern of distribution of defects of wing venation in the Banded Agrion

(*Calopteryx splendens*). *Russian Journal of Developmental Biology* 34(1): 51-56. (in English). ["The distribution of morphological structures was studied in wings of *C. splendens* from different intrapopulation groups. Damselflies of odd years of emergence are characterized by a more stable pattern of ontogenetic processes according to the mean total number of venation defects. The sharply increased level of radiation in summer 1986, which coincided with the flight of damselflies, could have caused hereditary defects expressed in a sequence of generations of even years of emergence. Apparently, most alternative features of wing venation in damselflies can be considered as markers of stability of the ontogenetic processes, which reflect, to a great extent, genotypic features of the organisms in a population. A possible mechanism has been described, which explains the proposed topological model of formation of the venation defects of different types. The increase in mean frequencies of defects can suggest an enhanced development over the aberrant epigenetic trajectories, which may lead to the elimination of these organisms under the influence of various agents, i.e., to the stabilizing selection in a population. The results obtained suggest that defects of venation arise on the stochastic basis and their frequency increases upon destabilization of ontogenetic processes not only by the environmental factors, but also by genetic stress. Venation defects can be successfully used in population biomonitoring." (Author)] Address: Muzlanov, Yu. A., Zarevskii Secondary School, Zarya, Mikhailovskii raion, Ryazan oblast, 391728 Russia

3431. Nobes, G. (2003): Small Red Damselfly *Ceragrion tenellum* in Norfolk. *Atropos* 19: 75-76. (in English). [Verbatim: "[...] *C. tenellum* was first reported breeding in Norfolk on 3 August 1955 (Durrant 1960) when a small colony was found, including several pairs seen in copula, at Seaming Fen. However, Ken Durrant (pers. comm.) says that as far back as 1937 he knew of a colony of this species at this site, when it was present in large numbers for many years. This small Norfolk Wildlife Trust Reserve, near Dereham, is still the only known site in the county for this species and is apparently also the only extant one in East Anglia. In recent years sightings have continued in very small numbers, though in some years there have been no records and the long-term future of the colony has been in doubt. Thus it is heartening to report that a ♂ of this species was seen on 15 July 2002 flying around the small Sphagnum moss pools where it breeds [...]."] Address: Nobes, G., Springside, Carbrooke, Thetford, Norfolk, IP25 6SQ, UK

3432. Nobes, G. (2003): Southern Emerald Damselfly *Lestes barbarus* (Fabr.) - The first British record. *Atropos* 18: 3-6. (in English). [On 30/07 and 7/08/2002, *L. barbarus* was recorded at Winterton Dunes, Norfolk, UK. This first mainland record for UK is documented in detail. A comment of Adrian Parr is added.] Address: Nobes, G., Springside, Carbrooke, Thetford, Norfolk, IP25 6SQ, UK

3433. O'Brien, M.; Bright, E.; Kielbaso, M.A. (2003): The Odonata of the Huron Mountains, Marquette Co., Michigan. *Bulletin of American Odonatology*: 1-22. (in English). [The Odonata fauna of the Huron Mountains - 26 localities were visited - was surveyed during 1996 - 2002. This survey, combined with specimens from earlier collectors resulted in a total of 79 species known

from the area, which is nearly half of Michigan's known Odonata species. In addition, 9 species are new records for Marquette County. Each of the species is briefly commented (habitat, habits), the records are documented locally wise.] Address: O'Brien, M., Insect Division, Museum of Zoology, University of Michigan, Ann Arbor, MI 48109-1079, USA. 3435. Padeffke, T.; Suhling, F. (2002): Temporal priority and intra-guild predation in temporary waters: an experimental study using Namibian desert dragonflies. *Ecological Entomology* 28(3): 340-347. (in English) ["1. Intra-guild predation between early larval instars of two co-existing dragonflies, *Sympetrum fonscolombii* and *Trithemis kirbyi*, was investigated with respect to temporal advantage and growth. Three situations were simulated experimentally: (1) *Sympetrum fonscolombii* began development 11 days before *T. kirbyi*. (2) *Trithemis kirbyi* began development 11 days before *S. fonscolombii*. (3) Both species began on the same day. 2. With a temporal advantage of 11 days to the second species, the resulting larval density of the respective first species was significantly higher than that of the second species. 3. Without a temporal advantage, the survival of *S. fonscolombii* was higher than that of *T. kirbyi*, and *S. fonscolombii* had a larger size due to faster growth than *T. kirbyi*. Hence, it is assumed that survival depended on early oviposition as well as on larval growth. 4. To test the relevance of the laboratory results, observations at artificial ponds in the Namibian semi-desert were conducted. *Trithemis kirbyi* was the first species colonising these ponds while *S. fonscolombii* arrived 15 days later. In field samples, many more *Trithemis* larvae than *Sympetrum* larvae were found, a pattern similar to the laboratory experiments in which *T. kirbyi* enjoyed a temporal advantage." (Authors) Address: Suhling F., Zool. Inst., TU Braunschweig, Fasanenstr. 3, D-38092 Braunschweig, Germany. E-mail: f.suhling@tu-bs.de

3446. Paulson, D.R.; Buden, D.W. (2003): The Odonata of Pohnpei, Eastern Caroline Islands, Micronesia. *International Journal of Odonatology* 6(1): 39-64. (in English). ["A collection of 448 Odonata specimens made on Pohnpei, Caroline Islands, Micronesia, in 2001-2002 allows a reassessment of the fauna of this small, isolated island. There are 15 species, including six species of the zygopteran genus *Teinobasis*, which apparently speciated in situ, an unusually great diversity for such a small island. One of these species was undescribed. A revised key to the *Teinobasis* of Pohnpei is included, the larvae of three species of *Teinobasis* are compared, and the ♀♀ of *T. aerides* and *Pacificothemis esakii* are described for the first time. The three odonate species represented by adequate series, *T. ariel*, *T. fortis*, and *Hemicordulia haluco*, appear to increase in body size with elevation. The island still has all of its natural habitats, although native upland forests continue to decrease as more land is cleared for agriculture. All of the odonate species seem secure at this time, although *T. nigrolutea* appears to be less common now than in the past." (Authors)] Address: Buden, D.W., Division of Natural Sciences and Mathematics, College of Micronesia-FSM, P.O. Box 159, Kolonia, Pohnpei FM 96941, Micronesia. E-mail: donbuden@comfsm.fm

3453. Purse, B.V.; Thompson, D.J. (2003): Reproductive morphology and behaviour in *Coenagrion mercuriale* (Charpentier) (Zygoptera: Coenagrionidae). *Odonatologica* 32(1): 29-37. (in English). ["The reproductive morphology and behaviour of ♂ and ♀ at the northern edge of the species range, in Britain are described. Copula duration was relatively short and occurred in tussocks around the stream and oviposition usually occurred in tandem. Although there was no significant relationship between body size and clutch size, large clutches were only found in the largest individuals and larger ♀♀ produced larger, and thus better-provisioned eggs. Examination of the dimensions of the aedeagus and the ♀ sperm storage organs revealed that ♂♂ could remove rival sperm from both the bursa copulatrix and spermatheca consistent with the presence of extensive proximally oriented microspination with sperm masses on the surface of the aedeagi. ♀ store sperm from previous matings and a few partition clutches between consecutive oviposition episodes. The fulfilment of these ecological and behavioural pre-requisites and the predominance of mate guarding during oviposition suggests that sperm competition by sperm displacement is prevalent in this species and constitutes a substantial selection pressure." (Authors)] Address: Thompson, D.J., Population Biology Research Group, School of Biological Sciences (Nicholson Building), University of Liverpool, P.O. Box 147, Liverpool, L69 3BX, UK. 3455. Reinhardt, K. (2003): Aspects of the reproductive behaviour and physiology in three north American Gomphidae species (Anisoptera). *Notul. odonatol.* 6(1): 4-8. (in English). ["Field and laboratory observations on the reproduction of *Gomphus externus*, *G. graslinellus*, and *Progomphus obscurus* are presented from Illinois, United States. Mating of *G. externus* in the field took 12 min. 2 phases were distinguished, the first consisted of tapping movements of the ♂ hamulus, the second of pumping movements of the ♀ abdomen. The ovary yielded 5100 eggs of which 690 were laid during hand-held oviposition in the laboratory. Only eggs laid by the ♀ but not the ones dissected from the ovary developed a sticky jelly coat around themselves. Eyespots of developing embryos were visible after 13 days. This ♀ had stored approximately 200 thousand sperm (about 160 bundles) in her spermatheca. The sperm were still mobile 3 days after mating. A comparison of the penis horn length and the length of the spermathecal tubes revealed that ♂♂ cannot reach the end of the spermathecal tubes. A *G. graslinellus* ♀ was observed to employ the dipping mode of oviposition. After oviposition she had approximately 1 million sperm remaining. ♀♀ of both species showed no muscle contraction response when the cerci were touched with water, but responses to water differed between the 2 ♀ on segments 9 and 10. ♂ *P. obscurus* perched on the sandy ground along the bank without territorial behaviour though ♂♂ were observed to follow other ♂♂. The penis morphology of *P. obscurus* was similar to members of the genus *Gomphus*.] Address: Reinhardt, K., Dept Animal and Plant Sciences, University of Sheffield, Sheffield S10 2TN, UK. E-mail: bgykr@leeds.ac.uk

3456. Relyea, R.A.; Hoverman, J.T. (2003): The impact of larval predators and competitors on the morphology and fitness of juvenile treefrogs. *Oecologia* 134: 596-604. (in English). ["Studies of phenotypic plasticity typically focus on traits in single ontogenetic stages. However, plastic responses can be induced in multiple ontogenetic stages and traits induced early in ontogeny may have lasting effects. We examined how gray treefrog larvae altered their morphology in four different larval environments and whether different larval environments affected the survival, growth, development, and morphology of juvenile frogs at metamorphosis. We then reared these juveniles in terrestrial environments under high and low intraspecific competition to determine whether the initial differences in traits at metamorphosis affected subsequent survival and growth, whether the initial- phenotypic differences converged over time, and whether competition in the terrestrial environment induced further phenotypic changes. Larval and juvenile environments both affected treefrog traits. Larval predators - *Anax*. sp. - induced relatively deep tail fins and short bodies, but there was no impact on

larval development. In contrast, larval competitors induced relatively short tails and long bodies, reduced larval growth, and slowed larval development. At metamorphosis, larval predators had no effect on juvenile growth or relative morphology while larval competitors produced juveniles that were smaller and possessed relatively shorter limbs and shorter bodies. After 1 month of terrestrial competition among the juvenile frogs, the initial differences in juvenile morphology did not converge. There were no differences in growth due to larval treatment but there were differences in survival. Individuals that experienced low competition as tadpoles experienced near perfect survival as juvenile frogs but individuals that experienced high competition as tadpoles suffered an 18% decrease in survival as juvenile frogs. There were also morphological responses to juvenile competition, but these changes appear to be due, at least in part, to allometric effects. Collectively, these results demonstrate that larval environments can have profound impacts on the traits and fitness of organisms later in ontogeny." (Authors)] Address: Relyea, R.A. & J.T. Hoverman, Department of Biological Sciences, University of Pittsburgh, Pittsburgh, PA, 15260 USA. E-mail: relyea@pitt.edu

(in Swedish with English summary) [Some personal reflections and memories from the 2002 Nordic Odonatological Society meeting in Gadevang, Denmark: The paper includes some photographs of the participants and *Libellula fulva*, and a list of the 24 odonate species collected at 10 localities. Of special interest are records of *Nehalennia speciosa* and *Leucorrhinia pectoralis*. Address: Sahlén, G., Höskolan i Halmstad, SET, Box 823, SE-301 18 Halmstad. E-mail: goran.sahlen@set.hh.se

3459. Samraoui, B.; Weekers, P.H.H.; Dumont, H.J. (2003): Two taxa within the north African *Lestes virens* complex (Zygoptera: Lestidae). *Odonatologica* 32(2): 131-142. (in English). ["A study of *Lestes "virens"* in Algeria, based on SEM, size analysis, and molecular analysis of nuclear ribosomal DNA genes (18S, 5.8S) and spacers (ITS1 and 2), reveals the presence of two taxa that can be separated by the length and sequence of their ITS1 and their adult coloration, but not by molecular features in their 18S and 5.8S genes, the ITS2 spacer, and morphology. This contrasts with the *Enallagma cyathigerum*-gro, where geographically defined morphological differences were unaccompanied by differences in ITS1 and ITS2. Previous ecological data had shown the first lestid to be a summer, and the second an autumnal reproducer. The red autumnal species is here named *Lestes numidicus* sp. n. (holotype ♂, allotype ♀: Algeria, Lac des Oiseaux, X-1993; deposited in IRSN, Brussels); the status of the green summer species is discussed. It probably corresponds to *L. virens*, but this is likely to be a hybrid taxon, resulting from the postglacial introgression of *L. numidicus* with a taxon invading from the East, via the Iberian Peninsula.

L. virens vestalis from France is likely to be introgressed as well. In case this hypothesis is confirmed, the first junior synonym available, *L. marikovskii* (Belyshev) from Kazakhstan, applies to the taxon extending from Kazakhstan-Tajikistan to Central Europe." (Authors)] Address: Dumont, H.J., Univ. Gent, Inst. Animal Ecology, K.L. Ledeganckstraat 35, B-9000 Gent, Belgium. E-mail: Henri.Dumont@rug.ac.be

3460. Samways, M.J. (2003): Conservation of an endemic odonate fauna in the Seychelles Archipelago. *Odonatologica* 32(2): 177-182. (in English). ["The odonate species richness of the granitic islands of Seychelles, a biodiversity hotspot, is significantly correlated to island size. The larger islands also have the highest elevations and hence the most streams from cloud catching as well as from downpours. The Seychelles odonate fauna can be divided into 2 groups: (1) endemic species, and, (2) geographically--widespread eurytopic, vagile species. The endemic species are elevational fugitives that need high-elevation forest cover, even if secondary. They are remarkably tolerant of temporary drying out of streams. In contrast, the widespread species occur at low elevations, are pool species, and are tolerant of removal of forest cover. They emigrate when the pools dry out. Conservation of the endemic taxa depends on maintaining cloud-catching forest, although evidence suggests that their populations are maintained even where the forest is partly alien invasive trees or secondary regrowth.] Address: Samways, M.J., Department of Conservation Ecology and Entomology, University of Stellenbosch, Private Bag XI, Matieland 7602, South Africa. E-mail: samways@sun.ac.za

3461. Samways, M.J. (2003): Threats to the tropical island dragonfly fauna (Odonata) of Mayotte, Comoro archipelago. *Biodiversity and Conservation* 12(9): 1785-1792 (in English) "The dragonfly fauna of the 374 km² island of Mayotte in the western Indian Ocean comprises some widespread African species and some Comoro endemics, and is a biodiversity hotspot. This dragonfly assemblage is under threat from increasing human impact as it creeps up the water courses from the periphery of the island towards the centre. Among these impacts are indigenous tree removal and replacement growth by alien vegetation. An even greater impact and threat is detergent input into streams. The intensity of this impact is so great that the streams and rocks become white. To date, although often the wings and bodies of odonates become stained white with detergent, the dragonfly assemblage appears remarkably tolerant of this impact. However, there is differential impact, with loss of island endemic species in the most impacted areas. In contrast, the geographically widespread and eurytopic species continue to thrive in these impacted areas, at least in the short term. It is urgent to change people's water-usage behaviour, both for their benefit and for the endemic dragonfly assemblage." (Author) Address: Samways M.J., Invertebrate Conservation Research Centre, Dept Zool. & Entomol., University of Natal, P/Bag X01, Scottsville 3209, Pietermaritzburg, South Africa. E-mail: samways@un.ac.za

3462. Sasamoto, A. (2003): Aberrant wing colouration in a *Neurothemis fluctuans* (Fabr.) ♂ (Anisoptera: Libellulidae). *Notul. odonotol.* 6(1): 12. (in English). [The brown wing markings in the ♂ are one of the distinctive features of the wide spread Asian *N. fluctuans*. The brown area in the forewing extends from wing base to

close to pterostigma, whereas in the hindwing, at the costal side it reaches almost the same level as in the forewing, but at the margin it bends towards the wing base. In immature stage the spots are pale yellowish, becoming gradually darker with maturity. In the ♀, the wing colouration is variable: from almost colourless to such resembling the ♂. On May 2, 2001, the author captured an aberrantly coloured ♂ at Pondok Tanjung, Perak, in peninsular Malaysia. Its forewing is similar to a typical ♂, but the hindwing colouration is much different. Only 2 or 3 costal cells are patchy brown, the remaining area of the standard spot being pale yellow. The colouration is symmetrical in both wings. Specimens with "normal" and aberrant wing colouration are figured.] Address: Sasamoto, A., 190-4 Yakuoji Tawaramoto-cho, Shiki-gun, Nara pref., 636-0341, Japan

3463. Schmidt, E. (2003): Die Torf-Mosaikjungfer *Aeshna juncea* (L., 1758) (Odonata, Aeshnidae) an Tontümpeln und an Gartenteichen im West-Münsterland und in Essen, ein ökologisches Rätsel. *Verh. Westd. Entomol. Tagung 2001*: 75-80. (in German). [Discussion of records of *A. juncea* at "atypical" habitats (clay pits, garden ponds). These habitats are compared with the typical habitats of the species in the region (transition mires, bogs). Proximate factors seem to be the structure of the vegetation, the ultimate factor may be the microclimate.] Address: Schmidt, E., Coesfelder Str. 230, D-48249 Dülmen, Germany

3464. Scott, D.A. (2003): Reports from Coastal Stations - 2002: Dursey Island, Co. Cork. *Atropos* 18: 68-69. (in English). [United Kingdom; *Sympetrum striolatum*] Address: not stated

3467. Srygley, R.B. (2003): Wind drift compensation in migrating dragonflies *Pantala* (Odonata: Libellulidae). *Journal of Insect Behavior* 6(2): 217-232. (in English) ["Tailwind drift compensation serves to maximize a migrant's flight distance on a given amount of energy, and crosswind drift compensation serves to hold a course true and minimize the distance flown. With full or part compensation, airspeeds are predicted to increase with greater crosswind drift. To test whether migrating dragonflies compensated for wind drift, I measured the velocity and heading of *Pantala hymenaea* and *P. flavescens* in natural flight over a lake and the ambient wind speed and direction. *P. hymenaea* flew north-easterly (58°), whereas *P. flavescens* flew significantly more east-north easterly (74°) throughout the day. *Pantala* spp. demonstrated part compensation for changes in crosswind drift within individuals (mean compensation = 54%, P = 0.0000), evidence for use of a ground reference to correct for drift when flying over water. Among individuals, *P. flavescens* compensated for crosswind

drift. P. hymenaea overcompensated and then drifted downwind on one morning and compensated for cross-wind drift on the next. As predicted from optimal migration theory, airspeed (5.0 m/s for both species with no tailwind) decreased with tailwind velocity both among individuals (data for both species pooled [n = 19], P < 0.0001) and within each individual as it crossed the lake (P = 0.0016)." 3469. Szállassy, N.; Bárdosi, E.; Szabó, Z.D.; Szép, T.; Dévai, G. (2003): Fluctuating asymmetry, survival and mating success in ♂ *Libellula fulva* Müller (Anisoptera: Libellulidae). *Odonatologica* 32(2): 143-151. (in English). ["The studies were conducted at Kutas canal near Ártánd, Hungary. In order to reveal whether there is any relationship between wing fluctuating asymmetry and mating success in mated (observed at least once in wheel position) and solitary ♂♂ (not involved in pairing during the study period), 106 ♂♂ were marked and their wing length between arculus and pterostigma measured. Mated ♂♂ had more symmetrical forewings, but in the case of hindwings there were no differences between solitary and mated individuals. The survival rate did not differ between the 2 groups and it was constant over time. The probability of recapture was higher in mated ♂♂ and varied with time. The number of hours spent with observation did not explain the variation in the recapture rate." (Authors)] Address: Szállassy, N., Department of Ecology and Hydrobiology, University of Debrecen, Egyetem tér 1, HU-4032 Debrecen, Hungary. E-mail: szallassy@tigris.klte.hu

3470. Szállassy, N.; Bárdosi, E.; Zoltán, S.D.; Tibor, S.; Dévai, G. (2002): Fluctuating asymmetry, survival and mating success in males of dragonfly *Orthetrum coerulescens* (Odonata: Libellulidae). *Hidrológiai Közlöny* 82: 125-127. (in Hungarian, with English summary) [The studies were conducted in a population along a slow flowing creek. Survival rate of unpaired ♂♂ differed significantly from that of paired ones on the first 2 days after marking; in both paired and unpaired ♂♂ it became constant later. Recapture rate differed in the 2 groups and changed in time. Neither the forewings nor the hindwings differed significantly in their fluctuating asymmetry values between the paired and the unpaired ♂♂.] Address: Szállassy, N., Dept Ecol. Hydrobiology, Univ. of Debrecen, Egyetem tér 1, HU-4032 Debrecen, Hungary. E-mail: szallassy@tigris.klte.hu

3471. Tagg, D. (2003): Raising *Brachytron* Larvae. *Dragonfly news* 43: 34. (in English). ["In May 1999 a ♀ *Brachytron* was ovipositing in the small pond at Sparr Rough nr Wisborough Green. She seemed to lay exclusively into dead soggy stems of the rush *Juncus effuses*, laying ar or just below the water surface. In one stem she appeared to have deposited at least 8 eggs. I took this home and kept it in a jar of water and in fact 19 larvae hatched out 3 weeks later, all neatly synchronised on the same day. They were given plenty of *Daphnia* and *Cyclops*, but within a month, although tiny and delicate-looking, they started eating each other in the traditional dragonfly manner! I returned some to the

pond and concentrated on keeping four individuals. Two died for no apparent reason in the winter of 2001/2001 but the other two flourished and grew on schedule for hatching in May 2001. In April one killed and ate the other, although they were of a similar age and until then had avoided one another. They had eaten aquatic worms, Chironomid larvae and damselfly nymphs. Water Hoglouse were also taken but usually tackled when the *Asellus* were moulting. *Brachytron* larvae are much more sluggish than *Aeshna* larvae, clinging to the same piece of weed or debris and hardly moving for days at a time. They cling tightly to a finger if fished out of the water." (Author)] Address: Don Tagg, Farnham, Surrey, UK

3478. Vischer, M.; Binot-Hafke, M. (2003): Artenhilfsprogramme der Bundesländer: Fauna. Natur und Landschaft 78(2): 56-63. (in German with English summary) ["In Germany there are currently 239 conservation action plans and programmes for 153 taxa groups which are (at least partially) financed and supported by the German regional states (Länder). 55 % of the programme's involve not only population records and conservation measures, but also evaluation and monitoring activities. Most programmes take vertebrates in consideration (76 %), especially birds. The present article is followed by tables of plans, programmes and measures implemented, sorted both by species group and regional state. These tables also indicate the degree of success as reported by the regional states." Special conservation action plans referring to Odonata are existing in Baden-Württemberg ("15 priority odonate species"), Bavaria (*Coenagrion lunulatum*, *C. mercuriale*, *C. ornatum*, *Nehalennia speciosa*, *Leucorrhinia pectoralis*), Bremen (*Aeshna grandis*, *A. viridis*, *Anaciaeschna isosceles*), Hamburg ("threatened odonate species"), and Thüringen (*C. mercuriale*, *C. ornatum*).] Address: Binot-Hafke, Margret, Bundesamt für Naturschutz, Fachgebiet 11.1 Zoologischer Artenschutz, Konstantinstr. 110, D-53179 Bonn, Germany

3479. Wain, B. (2003): A nice day out! Bill Wain in Oz. Dragonfly News 43: 20-21. (in English). [Report on observing *Petalura hesperia* south of Perth, Australia. A brief note on oviposition (?) of a ♀ *Petalura* sp. on a dark blue roof of a car is made.] Address: not stated

3480. Wallace, I. (2003): Late winter nymph of *Sympetrum fonscolombii* from N. Wales. Dragonfly news 43: 34. (in English). [Verbatim: "On 13.2.2001 I took a mature nymph of *S. fonscolombii* from a shallow, two year old pool constructed on the reclaimed pit heap at Point of Ayr Colliery (grid reference SJ12-83-). [...] The nymph is 17 mm long with wing pads stretching to the end of the 7th segment, and showing venation. It might have emerged successfully if not collected, but temperature data from the nearby Bidston Weather Observatory (available on the WWW) indicates that there was quite a severe cold spell at the start of March 2001, the most severe for the entire 2000/ 2001 winter, with several successive days of minimum temperatures lower than -2°C; a soil temperature data logger operated as part of studies on the Sandhill Rustic Moth at nearby Gronant, by Adrian Spalding also recorded sub-zero soil temperatures during that cold spell. Adrian Parr informs me that an adult was taken at Heysham on 30.6.2001, which as the crow flies is about 50 miles ac-

ross Liverpool Bay. Tantalisingly this could have been locally bred, but Adrian thinks it could also have been from an early spring 2001 migration. [...]"] Address: Wallace, I., Liverpool Museum, William Brown Street, Liverpool L3 8EN, UK. Ian.Wallace@nmgm.org

3481. Watanabe, M.; Mimura, Y. (2003): Population dynamics of *Mortonagrion hirosei* (Odonata: Coenagrionidae). International Journal of Odonatology 6(1): 65-78. (in English). ["The mark-and-recapture method was used to study the population dynamics of the endangered brackish water species, *Mortonagrion hirosei*, in a small reed community of an estuary in the warm-temperate zone of Japan. The flying season was from late May to early August. The age structure showed that newly emerged adults always stayed in the reed community and the maiden flight did not involve leaving the colony area. Although reed communities were abundant in the estuary, it appears possible that none or only very few of the individuals emigrated. Thus, both sexually immature and mature adults coexisted in the same reed community. The average distance covered by daily movements was 1.7 and 3.3 m for immature and mature ♂♂ respectively, which were longer than those for ♀♀. Since the average durations of the immature and reproductive periods were respectively about 5 and 30 days in both sexes, the individuals may have moved less than 110 m throughout their life span, which corresponds to twice the length of the habitat. The estimated daily number of adults in the community was about 200 in 2000 and 500 in 2001. As the population was isolated, the estimated input of new individuals into the population had to be the number of individuals emerging. Thus, the total number of adults in both years was estimated to be about 5,000 and 6,000 respectively." (Authors)] Address: Watanabe, M., Institute of Biological Sciences, University of Tsukuba, Tsukuba 305-8572, Japan. E-mail: watanabe@kankyo.envr.tsukuba.ac.jp

3482. Weihrauch, F.; Weihrauch, S. (2003): Spring Odonata from Alentejo (Portugal), Andalusia and Extremadura (Spain). Opusc. zool.flumin. 207: 1-18. (in English) ["An annotated list of 25 species recorded on the wing or as exuviae during 2 journeys to SW Iberia in spring 1999 and 2001 is presented. 3 more species were recorded as larvae. Phenological data were compared with data from the literature, obtaining particularly noteworthy early records for *Gomphus simillimus*, *Cordulegaster boltonii*, *Brachythemis leucosticta*, and *Sympetrum striolatum* for the region. For most species recorded, additional notes on biology or an assessment of abundance and distribution in the region in spring are given. The status of *Paragomphus genei*, *Anax ephippiger*, *C. boltonii*, *Oxygastra curtisii*, *Macromia splendens*, *B. leucosticta*, *Sympetrum fonscolombii*, and *S. striolatum* is discussed. *Brachytron pratense* was not encountered at localities with former records given in the literature and the possible extinction of the outstanding population in the Goto Donana is apprehended."] (Authors) Address: Weihrauch, F., Hengelerstr. 9, D-80637 München, Germany. E-mail: Florian.Weihrauch@t-online.de

3483. Wildermuth, H. (2003): Fortpflanzungsverhalten von *Somatochlora arctica* (Zetterstedt) (Anisoptera: Corduliidae). Odonatologica 32(1): 61-77. (in German with English summary). ["The reproductive behaviour in relation to structural habitat resources was studied at

mountain bogs of the Centra] Alps (Tyrol, Austria). The ♂♂ searched for mates at small clearings in coniferous forests where numerous scattered oviposition sites were hidden in dense vegetation, using 3 tactics: (1) they scanned the oviposition sites by slow flights at low height over large vegetated areas (scan flight). (2) they patrolled restricted areas with frequent hover stops while chasing any intruder (patrol flight), (3) they dived repeatedly into gaps of emergent vegetation, searching for ♀♀ close to the water (dive flights). 62% of the ♀♀ remained undiscovered by ♂♂. 11% fled successfully and 27% accepted copulation (n = 139). The copulation was always initiated in the air or on the ground when both partners plunged into the vegetation following a clash. Immediately after the take off and possibly after intra♂ sperm translocation the tandem assumed the wheel position. The pairs often circled over the clearings for several minutes and perched on sunlit branches of spruce or pine trees. 0.8-12 m above ground (mean 2.75 m. n = 20). During copulation that lasted 31-150 min (mean 85 min. n = 14) rhythmic pumping movements of the 6 basal abdominal segments with frequencies from 0.14 to 0.36 Hz were observed. Copulation terminated by disengagement of the genitalia, then the partners separated immediately or after a short tandem flight. Oviposition never followed directly upon copulation and always occurred unguarded. The oviposition sites were selected carefully at shallow puddles among emergent vegetation. Eggs were laid by touching soaked moss or turf mud with the tip of the abdomen during rhythmic dipping flight movements with mean frequency of 0.61 Hz. One oviposition bout lasted 1-3 min and featured an egg flow of 1.7-4.5 eggs per s. Ovipositing ♀♀ were sometimes successfully attacked by frogs (*Rana temporaria*). and ♂♂ were occasionally found in orb-webs of spiders (*Araneus* sp.), however, predation risk was low at rendez-votis sites. Sperm competition is discussed with respect to behaviour during copulation and to the morphology of ♂ and ♀ genitalia." (Author)] Address: Wildermuth, H., Haltbergstr. 43, CH-8630 Rütli, Switzerland. E-mail: hansruedi@wildermuth.ch

3485. Worthen, W.B. (2003): Nested-subset structure of larval odonate assemblages in the Enoree River basin, USA. *International Journal of Odonatology* 6(1): 79-89. (in English). ["Communities have a nested-subset structure if the species found in species-poor assemblages are also found in progressively more species-rich assemblages. This nested-subset structure can be caused by differential colonization rates among species, differential extinction rates among species, or nested niche space. In this study, the assemblages of larval odonates in the Enoree River of South Carolina (USA) and nine of its tributaries were found to have statistically significant nested-subset structure. In addition, the degree of nestedness in these ten streams correlated with several chemical and physical variables. Nestedness was correlated with pH, turbidity, and concentrations of silica, bicarbonate, and calcium; suggesting that differential extinction in response to environmental stress may play a role in structuring these assemblages. However, nestedness also correlated with a crude measure of habitat homogeneity. Drainages with a heterogeneous mix of substrate types (cobbles and sand) maintained different sets of species from site to site, and had the lowest nestedness scores. Drainages with exclusively sandy substrates were dominated by burrowing species at all sites, and showed the strongest nested-subset patterns. As such, nested-subset structure in these assemblages is related to both chemical and physical parameters." (Author)] Address: Worthen, W. B., Dept of Biology, Furman University, Greenville, SC, USA, 29613. E-mail: worthen@furman.edu

3486. Zhou, W. (2003): *Macromia hamata* sp. nov. from Guizhou, China (Odonata: Corduliidae). *International Journal of Odonatology* 6(1): 91-93. (in English). [*M. hamata* (holotype ♂: 01 August 2001, Fanjingshan, Guizhou, China) is described and illustrated from a single ♂, deposited at the Zhejiang Museum of Natural History.] Address: Zhou Wenbao, Zhejiang Museum of Natural History, Jiaogonglu 71, Hangzhou 310012, China

Management measures are proposed.] Address: Elsner, O., Inst. für Vegetationsk. und Landschaftsökologie, Georg-Eger-Str. 1b, D-91334 Hemhofen/Zeckern, Germany
- 3489.** Hilfert, D.; Rüppell, G. (1997): Early morning oviposition of dragonflies with low temperatures for male avoidance (Odonata, Aeshnidae, Libellulidae). *Entomol. gen.* 21(3): 177-188. (in English with German summary). ["The relationship between oviposition by females and the beginning of male flight activity, on the one hand, and air temperature and time of day, on the other, was investigated in Northern Germany, in Southern France and in Japan. Females of some Anisoptera species, as females of *Orthetrum cancellatum*, *Aeshna cyanea*, and *A. mixta*, avoid further matings by appearing before the males at oviposition sites, when air temperature are still low. In contrast, the females of *Anax imperator* are able to defend themselves against males successfully. Females of the Aeshnidae in S-France and in Japan fly to oviposition with higher air temperatures than the females of Aeshnidae in N-Germany. In the Zygoptera examined here (*Ischnura elegans*, *Coenagrion puella*), there is no such male avoidance strategy involving oviposition at lower temperature to avoid males. Here the beginning of oviposition and male flight activity is determined by the mating system." (Authors)] Address: Rüppell, G. Zool. - 3493.** Tremblay, A.; Lucotte, M. (1997): Accumulation of total mercury and methyl mercury in insect larvae of hydroelectric reservoirs. *Can. J. Fish. Aquat. Sci.* 54: 832-841. (in English with French summary). ["Mean total mercury (Hg) and methyl mercury (MeHg) concentrations in insect larvae from hydroelectric reservoirs were 3-5 times (up to 10 times) higher than in their counterparts from natural lakes. Taxonomic differences, which may be related to feeding behavior, and substrate type (lake sediment or flooded soils) together explained a large part of the total variability of total Hg ($r^2 = 0.64$) and MeHg ($r^2 = 0.79$) concentrations in insects. MeHg concentrations in flooded soils increased from 0.3-2 ng Hg.g dry weight⁻¹ after 1-2 years of flooding to 15-2 ng Hg.g dry weight⁻¹ after 16 years of impound-

ment. Total Hg and MeHg concentrations in insect larvae followed a similar pattern, but only weak correlations of both total Hg and MeHg concentrations were found between flooded soils and insect larvae, suggesting that factors other than MeHg content of flooded soils also affect the accumulation of these compounds in insects. Our results indicate that suspended particulate matter eroded from flooded soils by wave and ice action and bacterial activity enhanced by the release of labile carbon and nutrients from the flooded soils may indirectly transfer MeHg from flooded soils to insect larvae." (Authors) Mercury concentration in Odonata is presented in several tables and graphs.] Address: Tremblay, A., Chaire de recherche en environnement, Université du Québec à Montréal, C.P. 8888, succursale Centre-Ville, Montréal, QC H3C 3P8, Canada. 3495. Wong, A.; McQueen, D.J.; Williams, D.D.; Demers, E. (1997): Transfer of mercury from benthic invertebrates to fishes in lakes with contrasting fish community structures. Can. J. Fish. Aquat. Sci. 54: 1320-1330. (in English with French summary). ["We examined the flow of mercury (Hg) from benthic invertebrates to fishes in lakes with contrasting fish community structure. The study was carried out in two whole lakes in south-central Ontario in 1992. Both were remote from direct sources of contamination and were chosen because of their physical and chemical similarities. Although the fish communities in the two lakes were qualitatively similar, the total number of fishes in Ranger Lake was an order of magnitude smaller than that in Mouse Lake. As a result of the lower net predation from benthivorous fishes, documented in earlier studies, Ranger Lake benthic invertebrate populations were significantly higher. However, benthic invertebrate taxa in Mouse Lake were generally larger and had higher Hg concentrations. This was partly attributed to the stunted growth of Mouse Lake fishes, which did not allow them to prey on larger benthos as a result of gape limitations. Despite the lower Hg concentrations in Ranger Lake benthos, total benthic invertebrate Hg pools were higher in this lake as a result of its higher total benthic invertebrate biomass. However, the transfer of total Hg from benthic invertebrates to fishes was higher in Mouse Lake due to the higher consumption rates of benthivorous fishes." (Authors) Data of biomasses, mean individual wet mass, Hg concentration, and mean Hg pool for "Odonata" are presented in tables.] Address: Wong, A.H.K., Division of Life Sciences, University of Toronto at Scarborough, 1265 Military Trail, Scarborough, ON M1C 1A4, Canada. [This identification key includes both imagines (focus) and larvae. The species in some cases are briefly commented. Some general information on Odonata and a bibliography comprising of 74 titles are added too.] Address: Haritonov, A.YU.; Laboratory of Insect Ecology, Biological Institute of the Siberian Branch of the Academy of Sciences, Frunze str. 11, RUS-630091 Novosibirsk, Russia

3499. Siva-Jothy, M.T.; Hadrys, H. (1998): A role of molecular biology in testing ideas about cryptic female choice. In: R. DeSalle & B. Schierwater (Eds.): Molecular approaches to ecology and evolution. Birkhäuser. Basel: 37-53. (in English). ["If cryptic female choice exists, observations on mating behaviour will not reflect the actual patterns of paternity. Genetic profiling techniques are needed to identify patterns of paternity (and sperm storage) that deviate from expectations based on behavioural observations. Our chapter addresses this problem in two parts. The first provides a critical review of the concept of cryptic female choice leading to a set of criteria required to demonstrate its occurrence. Second, we explore the repertoire of molecular methods available to answer certain questions about cryptic female choice in insects. The potential and limitations of polymerase chain reaction-based single locus and multilocus DNA fingerprint techniques are discussed along with the different options of analysing the data. Two case studies illustrate that sperm storage and usage in odonates might enable females to control paternity." 3503. Kano, K.; Miyahata, T. (1999): Evening foraging and thermal behavior in a male of *Trithemis aurora* (Burmeister). *Nature & Insects* 36(11): 32. (in Japanese). ["We sighted evening foraging and thermal behavior in a male of *Trithemis aurora* (Burmeister). We happened to see an individual of *Trithemis aurora* perching on a tip of stem of grass, of which height was 1.6 meter, at a foot path between fallow rice paddies at Oyasu, Kunigami-gun, Okinawa Prefecture in the evening of July 1, 2001. The place is not a suitable habitat of the dragonfly usually, and I aimed my camera at the dragonfly, that raised its abdomen upward. It often took off for preying small insects, and returned to the same tip of the grass, and took often obelisk posture to exposure its body to the setting sun. There were several tall grasses near the perch, and when the perch was shaded, the dragonfly changed its perch to the perch in the sunshine and took the same posture. In the hot daytime dragonflies usually take obelisk posture for avoidance of rising body temperature, however this time, the behavior was for raising body temperature in the cool evening. We stayed there from 6:30 to 7:20 p.m., L, and when the sun set, the dragonfly flew away for roosting." (Taken from the translation of Naoya Ishizawa in *Digest of Japanese Odonatological short Communications* 12).] Address: Miyahata, T., 2: 9-20-9 mitsumata-cho, Maebashi City, Gunma Pref., 371-0018, Japan

3504. Kano, K. (1999): Morning and evening swarms in *Chlorogomphus brunneus brunneus* Oguma near the seashore. *Yosegaki* 102: 40. (in Japanese). [Swarming behaviour - in most cases - of females is described in detail. In general, the swarms are feeding aggregations, in a few cases seizures of females by a male was observed. (more details can be taken from the translation of Naoya Ishizawa in *Digest of Japanese Odonatological short Communications* 12).] Address: Kano, K., 5-19-

17-01, Koishikawa, Bunkyo-ku, Tokyo, 112-0002, Japan

3505. Ram, R.; Prasad, M. (1999): On the collection of Odonata from Arunachal Pradesh, India. *Rec. zool. Surv. India* 97: 113-132. (in English). [92 species and subspecies from Arunachal Pradesh, NE India are checklisted and commented in detail with focus on the species distribution. 15 species are new stated records. Remarks on morphology of *Aciagrion pallidum* Selys 1891 and *Ceriagrion olivaceum* Laidlaw, 1914 are made.] Address: Prasad, M.; Zool. Surv. India, M-Block, New Alipore, Calcutta-700053, India

3506. Sabarth, A. (1999): Bedeutung von Substrat und Versandung für die Verteilung des Makrozoobenthos in naturnahen Heidebächen. *Dissertation, TU Braunschweig*: 98 pp. (in German). [The macrozoobenthos of three sand bottomed streams in the Lüneburger Heide (Niedersachsen, Germany) were surveyed with special emphasis on the habitat choice of the species in different sediment types, submerged snags, and alder roots. (Covering with) sand sediments was one of the most important factors to explain the (low) abundance of species. *Calopteryx splendens*, *C. virgo*, *Cordulegaster boltonii*, and *Ophiogomphus cecilia* have been recorded at the sampling sites. *O. cecilia* is vulnerable against sand sediment cover, and its abundance can be explained by the depth of cumulated sand sediment.] Address: not stated; Zool. Inst., TU Braunschweig, Fasanenstr. 3, D-38092 Braunschweig, Germany

2000

3507. Bach, L. (2000): Auswirkungen von Revitalisierungsmaßnahmen an dem Heidebach Ise auf dessen Libellenfauna. *Angewandte Landschaftsökologie* 37: 267-270. (in German with English summary). [Niedersachsen, Germany; monitoring the effects of revitalisation effects on the odonate fauna between 1991 and 1999, it was found that rheophilous species were favoured significantly; this refers especially to *Gomphus vulgatissimus*, *Ophiogomphus cecilia*, *Cordulegaster boltonii*, *Calopteryx splendens*, and *Platycnemis pennipes*. In total, 36 odonate species could be observed, of which 18 regularly were autochthonous. Year by year, larvae of rheophilous species spread over more stretches of the river, and adults could be observed in greater abundances.] Address: Bach, L., Hamfhofsweg 125b, D-28357 Bremen, Germany. E-mail: lotharbach@aol.com

3508. Bass, D. (2000): A preliminary study of aquatic macroinvertebrates from two springs in the Pontotoc Ridge Nature Preserve, Oklahoma. *Proceedings of the Oklahoma Academy of Science* 80: 105-109. (in English). [Little is known regarding the spring invertebrate fauna in Oklahoma, USA. The purpose of this investigation was to collect baseline data concerning the physicochemical conditions of the water and to determine distributions of macroinvertebrates in spring-brooks resulting from 2 springs (Pot Spring (34.4973°N, 96.6022°W) and Coal Creek Cave Spring (34.5247°N, 96.6014°W)) emerging on the property. *Argia* sp., *Cordulegaster* sp., *Hetaerina* sp., and *Lestes* sp. are listed in a table and classified according Surber Net Sample

Number and downstream distance from the spring.] Address: Bass, D., Biology Dept, University of Central Oklahoma, Edmond, Oklahoma 73034, USA.

3509. Buczynski, P.; Czachorowski, S.; Pakulnicka, J. (2000): Do small man-made water bodies can be a substitute habitat for the lake littoral benthos? In: Cerbin, S. (Ed.): Bottom Fauna of lakes. Materials of the VII Polish Benthological Workshop, Jezioro Wielkopolski National Park: 45-47. (in Polish). [The Odonata, Trichoptera, and Coleoptera of some gravel and sand pits near Olsztyn, Lublin-region, Poland were investigated. Emphasis is given to the fauna of different stages of vegetation succession. A total of 37 odonate species were found, but not details are given. A German translation of the paper is available from P. Buczynski.] Address: Buczynski, P., Dept of Zool., Marie Curie-Skłodowska University, Akademicka 19, PL-20-033 Lublin, Poland. 3510. Buczynski, P. (2000): Jak larwy wazek (Odonata) przezywaja wysychanie drobnych zbiorników? In: Czczuga, B. & J.L. Rybak (Eds): XVIII Zjazd hydrobiologów Polskich w Białymstoku. Szacunek dla wody. Materiały zjazdowe. 4-8. IX 2000. Polskie Towarzystwo hydrobiologiczne zakład biologii ogólnej am w Białymstoku: 33-34. (in Polish). [How do larvae of Odonata survive in drying out pools? Records on *Libellula depressa* and *Ischnura pumilio* - characteristic species of temporary water bodies - are referred: The larvae search successively for the most moisty places; shortly before the pools are totally drying out, they crawl in fissures. If it shouldn't rain, these specimens would die too. Larvae of *Coenagrion puella* and *Libellula quadrimaculata* protected themselves under a layer of *Lemna minor*, while *Aeshna cyanea* was found under leaves on the bottom of a pool. Here, they were able to survive a period of 3-4 weeks of drying out. A German translation of the abstract is available from P. Buczynski.] Address: Buczynski, P., Dept of Zool., Marie Curie-Skłodowska University, Akademicka 19, PL-20-033 Lublin, Poland. E-mail: pbuczyns@biotop.umcs.lublin.pl

3511. Clausnitzer, V. (2000): Interspecific competition in rainforest dragonflies (Tetratheminae, Libellulidae). Poster, 13. Jahrestagung der Deutschen Gesellschaft für Tropenökologie, 1.-3. März 2000 in Würzburg; <http://www.biozentrum.uni-wuerzburg.de/zoo3/gtoe/>: 1 pp. (in English). [Verbatim: It is generally hold that "displays of closely related species are clearly distinct so as to minimize the chance of confusion between species" (Krebs & Davies, 1993, p. 363). The similarity in morphology, colouring and behaviour of sympatric rainforest Tetratheminae does not fit this considerations. The territorial behaviour of two *Notiothemis* and one *Tetrathemis* species was studied in a West Kenyan rainforest. Males establish territories at small pools and keep them for several days. The territories are visited by females either for egg-laying or mating; males would approach any female and try to copulate, species determination being tactile only. Within *Notiothemis* inter- and intraspecific competition for the pools is nearly identical, *Tetrathemis* is inferior to the former. The number of territorial males depends on the pool circumference and vegetation cover; the number of territorial *Tetrathemis* being significantly correlated on presence or absence of *Notiothemis*. For both *Notiothemis* species the territory size is larger than for *Tetrathemis*. Neither behaviour nor colouring shows reduction of am-

biguity between the species. The inter- and intraspecific aggression is very similar; species recognition is by contact only. To minimise disturbance for approaching females the territorial male keeps all potential competitors away. In West African rainforests even more species of the Tetratheminae inhabit the same habitats, all showing very similar behavioural and colouring patterns. It remains unclear how such different species have evolved. Literature: Krebs, J. R. & Davies, N. B. (1993): An introduction to behavioural ecology. 420 pp. Blackwell Scientific Publications, Oxford.] Address: Clausnitzer, Viola, Liebenauer Str. 180, D-06110 Halle / Saale, Germany. - 3521.** Meadows, D.W. (2000): Effect of bison trampling on aquatic invertebrates in streams on Antelope Island, Utah. The Ecological Society of America, 85th Annual meeting August 6-10, 2000 Snowbird, Utah, Document: LAU-3-56-31 WA-3-84-2: (in English). [Verbatim: Trampling of riparian habitats by large herbivores can have significant impacts on aquatic communities. I examined numerous environmental variables and aquatic invertebrate community composition from paired trampled and untrampled sites in eight first or second order streams on Antelope Island, in the Great Salt Lake, Utah. Percent mud and sand substrates were more common in trampled sites in most streams, while percentage cover of aquatic vegetation was lower in trampled sites. Of the twenty taxa common enough to be analyzed statistically, five showed no difference in untrampled vs trampled areas, seven had consistent differences across streams, and eight had stream x trampling level interactions. Annelid worms, ostracods, the beetle *Helophorus*, and the snail *Physella* were more common in trampled areas while the odonate *Argia*, the beetle *Agabus*, the snail *Stagnicola*, the dipteran *Dixa*, hydrophilid beetles, limnephilid caddisflies, and simuliid and chironomid flies were more common in untrampled areas. These results can mostly be explained by direct trampling effects and indirect interactions of bison trampling affecting environmental features and substrate composition. These results suggest the need for managers and ranchers to control access of bison to riparian zones as is necessary for cows and sheep, even though bison wander more and spend much less total time in riparian zones.] Address: Meadows, D.W., Weber State University, Ogden, UT 84408 USA

[UK; phenological data of *Pyrrhosoma nymphula*, *Erythromma najas*, *Coenagrion pulchellum*, *Brachytron pratense*, *Aeshna mixta*, and *Sympetrum striolatum* from different British regions are documented. The current status of *Aeshna caerulea*, *Somatochlora arctica*, and *Leucorrhinia dubia* is briefly exemplified. "Mobbing" behaviour of *Calopteryx splendens* against an ovipositing female of *Anax imperator* is described. Mixed pairing between *Libellula fulva* and *L. quadrimaculata* is reported. Northward range extension of *Sympetrum sanguineum* is outlined.] Address: Perrin, V., 13 Pettitts lane, Dry Drayton, Cambridgeshire CB3 8BT, UK. E-mail: valperrin@dial.pipex.com

3528. Pintor, L.M.; Soluk, D.A. (2000): Understanding the interaction of crayfish and the Hine's Emerald Dragonfly larvae coexisting in crayfish burrows. The Ecological Society of America, 85th Annual meeting August 6-10, 2000 Snowbird, Utah, Document: LAU-3-56-31: (in English). [Verbatim: Biotic interactions, such as predation, can have significant influences on population dynamics, community structure, and the behaviors of organisms. Odonates are a group of organisms in which predation has been a major factor shaping the observed life histories and behaviors. While most studies have focused on the effect of vertebrate fish predators and intraguild predation, crayfish are another predator present in many aquatic systems that can have an effect on larval Odonate populations. Habitat duration can also influence larval Odonate communities by limiting the species that can maintain populations in variable environments. It can also effect the strength of biotic interactions between those organisms that persist. *Somatochlora hineana* inhabits small, ephemeral streamlets that experience seasonal drying; a situation intolerable for many larval Odonates. Field studies indicate that larvae use active crayfish burrows to survive through periods of drought. Crayfish are predators of dragonfly larvae, which raises the question of how these organisms coexist in burrows. To resist predation, *S. hineana* larvae may simply be distasteful or crayfish may fail to recognize them as prey. Lab experiments were conducted to establish whether a direct predator-prey relationship exists between *S. hineana* larvae and the crayfish, *Cambarus diogenes*. Results show that *C. diogenes* readily consume *S. hineana* and other dragonfly larvae, and are only limited by the size of the larvae relative to its own size. To further investigate predation by crayfish inside burrows and whether larvae avoid active burrows, we conducted a field exclusion experiment manipulating the presence of crayfish in burrows. Preliminary results of a repeated-measures analysis shows no significant difference between treatments ($p=0.87$), indicating that the presence of crayfish has no effect on *S. hineana* larval densities within burrows. This suggests either that larvae may not be able to discriminate between burrows with crayfish present/absent, or that the cost may not be high, relative to the benefits attained by inhabiting the burrow. *S. hineana* larvae probably exhibit unique behaviors that allow them to avoid predation by crayfish within burrows.] Address: Pintor, L.M.; Soluk, D.A., University of Illinois, Urbana-Champaign, Champaign, IL 61820, USA

3529. Ram, R.; Chandra, K.; Yadav, K. (2000): Studies on the Odonata fauna of Andaman and Nicobar Islands. *Rec. zool. Surv. India* 98(3): 25-60. (in English). [India; 58 species are listed resp. documented in detail, keyed, and discussed, incl. 8 species that are new to the fauna of the Archipelago, of which *Cratilla metallica* is for the first time recorded from the Indian territory. 3530. Rasch, P.; Trapp, M. Ein Fließgewässer im urbanen Umfeld. Analyse des ökologischen Zustandes des unteren Belmer Baches (Osnabrück, Niedersachsen) anhand des Makrozoobenthos. *Osnabrücker Naturwissenschaftliche Mitteilungen* 28: 167-190. (in German with English summary). ["The organic pollution of the lower Belmer Bach can be attributed to its agriculturally intensively used drainage area. Already before entering the urbanized region, the macrozoobenthos is poor in species due to saprobic pollution and the structural poverty of the waterbed and the banks. When comparing the species numbers of a reference sampling plot located before the urban region and a sampling plot situated within this region, hardly any differences could be ascertained. The longitudinal isolation and the rise in temperature of app. 1 °C in the urban brook section negatively influence its fauna; this, however, is compensated by the varied riparian vegetation and the greater structural diversity of the waterbed due to hydraulic engineering. A rise in temperature of app. 5 °C a continuous inflow of suspended matter from a sewageworks reduce the macrozoobenthos to few dominant taxa." (Authors) *Calopteryx splendens*, *Ischnura elegans*, *Letes sponsa*, *Chalcolestes viridis*, and *Zygoptera* are listed represented samples from May 1996, and May, July, and Sept. 1997.] Address: Rasch, P., Fachgebiet Ökologie, FB Biologie/Chemie, Universität Osnabrück, Barbarastr. 11, D-49069 Osnabrück, Germany

3531. Rutkowski, D.H. (2000): Dziemna i nocna zawartosc przewodów pokarmowych larw wazek równokrzydłych (Odonata, Zygoptera) w litoralu jeziora Kuc. In: Czeczuga, B. & J.L. Rybak (Eds): XVIII Zjazd hydrobiologów Polskich w Białymstoku. Szacunek dla wody. Materiały zjazdowe. 4-8. IX 2000. Polskie Towarzystwo hydrobiologiczne zakład biologii ogólnej am w Białymstoku: 226. (in Polish). [Daily site change in preying *Zygoptera* larvae in the litoral of lake Kuc. The diurnal and nocturnal dwellings of larval *Enallagma cyathigerum*, *Erythromma najas*, and *Ischnura elegans* were studied in a mesotrophic lake. During day time, Chironomidae and Ephemeroptera dominated as prey, while during night Cladocera were preferred. Preyed biomass in night was higher than on day. This is explained by a compromise between avoiding being preyed by fishes and searching for prey.] Address: Rutkowski, D.H., Zakład Hydrobiologii, Instytut Zoologii, Uniwersytet Warszawski, Poland

3532. Stav; G.; Kotler, B.P.; Blaustein, L. (2000): Direct and indirect effects of the predatory dragonfly nymph *Anax imperator* on green toad *Bufo viridis* tadpoles. The Ecological Society of America, 85th Annual Meeting, August 6-10, 2000 Snowbird, Utah, This abstract is being presented at: 9:00 AM in session: Oral Session #38: Amphibian Ecology, Document: GIL-3-56-2: (in English). [Verbatim: We conducted an artificial pool experiment to assess effects of the predatory dragonfly nymph *Anax imperator* on green toad *Bufo viridis*

tadpoles. We ran three treatments (with six replicate pools each): (1) free *Anax* (direct effects on mortality); (2) caged *Anax* (indirect effects on behavior, development and individual growth rates); and (3) control (no *Anax*). We added 15 liters (10 cm depth) of water to each pool. After five days, we added 30 three-day old tadpoles, all hatched from the same egg string. Caged *Anax* were fed with tadpoles three times a week. The experiment ran from 11 April through 4 August. Free *Anax* eliminated 90% of the tadpoles within three days and all of them within six days. Caged *Anax* had no effect on the spatial distribution of tadpoles. However, caged *Anax* caused tadpoles to metamorphose earlier to a larger size (both statistically significant), and to obtain lighter color. This study shows that *Anax* has a very strong direct effect on the population of *Bufo* tadpoles. Future experiments will be designed to determine whether the prey responses to the predator are reactions to predation or the result of extra organic matter in this treatment (consequence of *Anax* feeding and secretion).] Address: Stav, G., Ben-Gurion University of the Negev, Sede-Boqer Campus, 84990, Israel

3535. Adams, M.J.; Pearl, C.A.; Bury, R.B.; Nebeker, A.V. (2001): Introduced fish increases survival of introduced bullfrogs. Ecological Society of America Annual Meeting, 86th Annual Meeting in Madison, WI, August 2001: 41. (in English). [Verbatim: We hypothesized that nonnative bluegill (*Lepomis macrochirus*) are facilitating the survival of nonnative bullfrogs (*Rana catesbeiana*)

through an indirect effect mediated by dragonfly larvae (Aeshnidae) in western North America. Aeshnid larvae were capable of high predation rates on bullfrog larvae in laboratory experiments and reduced survival to zero in field enclosures with either native fish (*Richardsonius balteatus*) or no fish. Adding bluegill increased survival of bullfrog larvae from zero to 20% when aeshnids were present but had no effect when aeshnids were absent. Field surveys at 57 permanent ponds in Oregon and Washington revealed higher bullfrog abundance and lower predaceous macroinvertebrate abundance when nonnative fish were present but this pattern was weak. We conclude that bluegill facilitate survival of bullfrog larvae in PNW ponds but field surveys suggest that other factors may have more important effects on bullfrog distribution and abundance.] Address: Adams, M. 3540. Brendonck, L.; Michels, E.; De Meester, L.; Rid-doch, B. (2001): Temporary pools are not 'enemy-free'. *Hydrobiologia* 486: 147-159. (in English). ["Temporary pools are traditionally considered as refuges where the conspicuous anostracans are protected from predation. While this is true for the size-selective predation by fish, there is compelling evidence that invertebrate predation is an important biotic stress regulating temporary pool communities. In rock pools in southeastern Botswana, we studied the impact of some suspected invertebrate predators on populations of the freshwater anostracan *Branchipodopsis wolfi* by means of observations and manipulative experiments. In a survey of 45 pools, the relationship between *B. wolfi* natural population sizes and the abundance of suspected predators were never negative for turbellarians and mosquito larvae. When dragonfly larvae, notonectids or tadpoles were present, the anostracan populations were generally non-existent or very small. In enclosure experiments with turbellarians, there was a significant effect of predation within one hour of the start; the average daily predation rate was about 1/4 anostracan per turbellarian. Anostracans from a pool with few turbellarians were slightly less vulnerable than those from a turbellarian-rich pool. Furthermore, there was an indication of males being predated on more than females. With dragonfly larvae and notonectids, the predation effect was marked with all six anostracans in an experiment eaten in less than one day by a single predator (predation rate: about one anostracan every 2 h per predator). In a behavioral study, both sexes of *B. wolfi* avoided swimming above sediment that held more turbellarians than the open patches; there was no evidence for chemical communication with respect to this behavior." (Authors)] Address: Brendonck, L., Laboratory of Aquatic Ecology, K.U. Leuven, De Beriotstraat 32, B-3000, Leuven, Belgium. E-Mail: Luc.Brendonck@bio.kuleuven.ac.be

The water courses of La Vèbre au Pertuis and the Lauzens are inhabited by

Cordulegaster boltonii immaculifrons, and *Onychogomphus f. forcipatus*.] Address: Faton, J.-M., Réserve Naturelle des Ramières, les Garis, F-26120 La Baume Cornillane, France. E-mail: Fatonjm@aol.com

3543. Gaines, K.H. (2001): Are 'sinkholes' aptly named? Larval odonate ecology and adult species diversity in southeastern New Mexico. *Ecological Society of America Annual Meeting, 86th Annual Meeting in Madison, WI, August 2001*: 281. (in English). [Verbatim: The Bitter Lake National Wildlife Refuge is an unusual complex of alkaline salt flats interspersed with wetlands and water-filled sinkholes. Recent collections of over ninety species of adult dragonflies and damselflies on the refuge suggest that the highest diversity of odonates in New Mexico may occur in this relatively small area. The composition of the resident breeding population and the factors that contribute to the observed adult species diversity were unknown. In order to resolve these issues, odonate exuviae, larvae, and adults were collected periodically at more than thirty-five sinkholes exhibiting a wide range of physical and biological characteristics. Habitat data (water chemistry, aquatic vegetation, and fish species assemblages) were also collected at each sinkhole and used to determine ecological correlates of larval species diversity and distribution. Exuviae of one odonate species were the only exuviae found at many of the sinkholes surveyed, indicating larval tolerance of a wide range of ecological conditions. In contrast, exuviae of several species observed as adults throughout the refuge were found at only a few sinkholes, suggesting larval stenotopy (primarily with respect to water salinity) and thus limited suitable breeding habitat availability for those species. The composition of species breeding successfully at sinkholes did not correspond to the adult species composition found to date, indicating that these sinkholes may indeed represent sinks for dispersing individuals rather than sources of species diversity.] Address: Gaines, Karen, Dept Biol., Univ. of New Mexico, Castetter Hall, Albuquerque NM 87131, USA. E-mail: kgaines@umm.edu

[The author briefly introduces into Japanese fossils (taken from layers of the later Miocene, the later Pliocene, and the later Pleistocene) and the process of fossilization in amber. He reports on collection material of the Kuji Amber Museum, Kuji City, Iwate Pref., Japan representing material from Domenica and Kaliningrad (Russia). (for more details see Digest of Japanese Odonatological Short Communications 12).] Address: Kano, K., 5-19-17-01, Koishikawa, Bunkyo-ku, Tokyo, 112-0002, Japan

3549. Kano, K. (2001): Dragonflies prey on cicadas, *Moganmia minuta* Matsumura. *Nature & insects* 36(1): 35. (in Japanese). ["I sighted *M. minuta* was preyed on by an expectedly lot of species of dragonflies at Kainan, Ishigaki island, on May 2- 5, 1995. It was cloudy and occasionally rainy. This cicada appears from March to July on Ishigaki island; the body length: 2.2-2.3 cm, the smallest in Japan, and it sings on ziiiiiii on leaves of sugar cane. It feeds on the sap from veins of leaves, and perches on the upper side in action and at rest on the underside. So far there have been a few report made on cicadas as prey of dragonflies; *Platypleura kaempferi* Fabricius by *Ictinogomphus clavatus* (Fabricius) (Corbet, 1999), *Graptopsaltria nigrofusca* Motschulsky by *Anotogaster sieboldii* (pers. com. Kurashina). Most of preys are Dipterans and *Moganmia minuta* of Hemipteran may be a rare case. I found a male *Asiagomphus yayeyamensis* (Oguma) subduing and eating a *M. minuta* at grass field in a branch stream of the Miyara River on Ishigaki island on May 2. The dragonfly bit the head of the prey and subdued the cicada, then chewing it, removing the wings onto the ground and finished consumption for five minutes. On that day two species were seen that preyed on *M. minuta* beside the dragonfly; *Orthetrum s. sabina* (Drury) and *O. pruinosum*

neglectum (Rambur). In general, there are two modes of foraging; one is midair foraging and the other, gleaning (Corbet, 1999). In Anisopteran dragonflies, they adopt mostly midair foraging and in Zygopteran, gleaning, glean small insects such as aphids perching on grasses. The above three species usually take the midair foraging mode, by darting to flying insects from their perches, however, in the afternoon on May 5 *O. s. sabina* attacked *M. minuta* that perched on a leaf of Japanese pampas grass, and the latter flew away with a scream. Thereafter I saw the dragonfly approached and attacked twice on *M. minuta* perched on grasses. In this case, dragonflies searched and attacked the preys perching on the upper side of leaves of grasses, though they usually hide underside of leaves. In gleaning capture success may be lower and not so more effective than midair foraging. It was cloudy and occasionally rainy, and flying insects were not seen, therefore the dragonflies took the mode of gleaning." (Taken from Digest of Japanese Odonatological Short Communications 12, 2002)] Address: Kano, K., 5-19-17-01, Koishikawa, Bunkyo-ku, Tokyo, 112-0002, Japan

3550. Knijf, G. de (2001): Libellen in Vlaams-Brabant: stand van zaken van het verspreidingsonderzoek. *Brakona jaarboek 2000*: 53-57. (in Dutch). [Odonata in Vlaams-Brabant: the current status of the mapping project - On a fundament of 39000 records, the current status of the knowlege on the odonate fauna of Vlaams-Brabant, Belgium is discussed. A total of 67 species is mapped; in the period between 1990-1999, 59 species could be recorded. Many species are discussed and all species are documented in a table. Their presence in three differnt periods and their grid-frequencies are outlined.] Address: Knijf, G. de, Instituut voor Natuurbehoud, Kliniekstraat 25, B-1070 Brussel, Belgium. others the paper of Sakwiewicz & Zak (1966) on the Silesian Odonata.] Address: Kuska, A., Katedra Nauk Biologicznych AWF, Katowice, ul. Raciborska 1, Poland

3554. Letowski, J. (2001): Aktualne kierunki badan entomologicznych w Zakladzie Zoologii UMCS. Polskie Towarzystwo Entomologiczne: 44 Zjazd, Polskiego Towarzystwa Entomologicznego, Materialy zjazdowe, Spala, 14 - 16 wrzesnia 2001, Poznan: 46-47. (in Polish). [Current research activities at the Dept of Zool., Marie Curie-Sklodowska University, Lublin, Poland, including Pawel Buczynski's impressive studies on Odonata are briefly outlined.] Address: Letowski, J., Dept of Zool., Marie Curie-Sklodowska University, Akademicka 19, PL-20-033 Lublin, Poland

3555. Margolis, B.E.; Raesly, R.L.; Shomway, D.L. (2001): The effects of beaver-created wetlands on the benthic macroinvertebrate assemblages in two Appalachian streams. *Wetlands* 21(4): 554-563. (in English). [The effects of beaver impoundments on the benthic macroinvertebrate assemblages were examined in 2 small streams in Somerset Co., Pennsylvania and Garrett Co., Maryland, USA. Cordulegaster was among the dominant taxa above the impoundment, Chromagrion, Calopteryx, Boyeria, Erythemis, and Plathemis occurred below the impoundment, and Gomphus and Epitheca within it. The presence of submerged aquatic vegetation was responsible for the Chromagrion and Boyeria occurrence below the impoundments. Generally, taxonomic and functional changes in benthic macroinvertebrate assemblages of the beaver-altered streams were a results of direct (impoundment) and indirect (changes in temperature, water chemistry, plant growth) alterations of the stream environment.] Address: Margolis, B.E., New Jersey Dept. Envir. Prot., Bureau Freshw. & Biol. Monitoring, P.O. Box 427, Trenton, NJ 08625-0427, USA)

3556. McPeck, M.A.; Turgeon, J.; Thum, R.; Stoks, R. (2001): Generating biodiversity: The phylogeography of a North American insect radiation. *Ecological Society of America Annual Meeting, 86th Annual Meeting in Madison, WI, August 2001*: 156. (in English). [Verbatim: Recent phylogenetic analyses have shown that two lineages of North American Enallagma damselflies (Odonata: Coenagrionidae) radiated very recently to give 18 extant species, and ecological studies have demonstrated that multiple habitat shifts occurred as part of this radiation. We are now using phylogenetic analyses using a 940 bp mtDNA fragment to reconstruct how speciation proceeded during this radiation. The phylogenetic relationships and geographic distributions of 54 haplotypes identify E. hageni as the ancestor of one radiating lineage. These data also show that E. hageni is comprised of disjunct Continental and Atlantic races that are indicative of restrictions to separate refuges during the last glacial period. Nine new species arose by at least three different speciation mechanisms from the Continental hageni race as it expanded its range following glacial retreat, but no new species arose from the Atlantic race. Three coastal plain endemics show very low genetic diversity and were each derived by a few populations differentiating from the Continental hageni in a local area. Three other widely distributed species show substantial polyphyletic origins within the Continental hageni. Parallel speciation events driven by habitat shifts appear to have created two of these species, and sharply contrasts with the apparent lack of ecologi-

cal differentiation in the third. These results taken with previous studies suggest that both ecological and non-ecological speciation mechanisms can simultaneously drive radiation events.] Address: Stoks, R., Laboratorium voor Aquatische Ecologie, K.U.Leuven, De Beriotstraat 32, B-3000 Leuven, Belgium. E-mail: rob-by.stoks@bio.kuleuven.ac.be

3557. Mocek, B.; Mikat, M. (2001): The second contribution to the knowledge of the dragonfly fauna (Odonata) in the Nature Monument "Na Plachte", eastern Bohemia, Czech Republic. *Acta Mus. reginaehradecensis* (A) 28: 135-142. (in Czech, with English summary). [Compared with records made between 1997-2000, the number of thermophilous species (e.g. Aeshna affinis, Anaciaeschna isoceles) has increased, while some psychrophilous taxa (species preferring lower temperatures) have disappeared (Leucorrhinia pectoralis, L. dubia). 5 species were added to the list, totalling now at 37 species.] Address: Mocek, B., Regional Museum of Eastern Bohemia, Dept Natural History, Eliscino Nábřeží 465, CZ-50001 Hradec Králové, Czech Republik. 3558. Monnerat, C. (2001): Prolongement de la periode de vol de certains odonates en octobre 2001. *Bull. romand Ent.* 19(2): 95-106. (in French with english summary). [An extension of the flying period in western Switzerland was noticed in October 2001 in several species, most particularly in Enallagma cyathigerum, Ischnura elegans, and I. pumilio. Bad weather conditions in September did not cause a significant mortality, and favourable weather in October favoured the adult longevity. The 2001 evidence is compared with 4990 observations made during 1989-2000, 99 of which were made in October. In addition, phenological of Calopteryx splendens, Chalcolestes viridis, Lestes sponsa, Sympecma fusca, Aeshna cyanea, A. grandis, A. juncea, A. mixta, Somatochlora arctica, Orthetrum brunneum, Sympetrum fonscolombii, S. pedemontanum, S. sanguineum, S. striolatum, and S. vulgatum are documented.] Address: Monnerat, C., Centre suisse Cartogr. Faune, Terreaux 14, CH-2000 Neuchatel, Switzerland. E-mail: christian.monnerat@cscf.unine.ch

3559. Napiórkowska-Kowalik, J.; Letowski, J. (2001): Stan poznania entomoloafauny Lublina. *Polskie Towarzystwo Entomologiczne: 44 Zjazd, Polskiego Towarzystwa Entomologicznego, Materialy zjazdowe, Spala, 14 - 16 wrzesnia 2001, Poznan: 50-51.* (in Polish). [The authors document the present knowledge on the entomofauna of the town of Lublin, Poland. Within the borders of the town, at present 28 odonate species could be traced.] Address: Letowski, J., Dept of Zool., Marie Curie-Sklodowska University, Akademicka 19, PL-20-033 Lublin, Poland

3560. Piotrowski, W. (2001): Wyniki badan entomologicznych w Poleskim Parku Narodowym do konca 2000 r.. *Polskie Towarzystwo Entomologiczne: 44 Zjazd, Polskiego Towarzystwa Entomologicznego, Materialy zjazdowe, Spala, 14 - 16 wrzesnia 2001, Poznan: 54-55.* (in Polish). [While in 1994, no odonate species were known for the Poleskie Nationalpark, Poland, 51 species had been recorded in the succeeding period up to 2000.] Address: Piotrowski, W., Poleski park Narodowy, Urszulin, Poland

3561. Rolando, A. Boano, G. (2001): Aggressive interactions and demographic parameters in Libellula fulva

(Odonata, Libellulidae). *Advances in Ethology* 36: 253-254. (in English). [Verbatim: Male aggressive interactions and demographic parameter of the dragonfly *Libellula fulva* were studied for four years at a low marshy site in north-western Italy. Individuals were caught and marked with white marking fluid. Perching males attacked every dragonfly passing near the perch. The mean conspecific attack distance was significantly longer than the heterospecific one and this suggests that males were able to discriminate among species, at least partially. Sex ratio was very biased toward males and adult females were in fact rather rare. Life span estimates were similar to field observations, both suggesting most males stayed alive for less than 10 days. Male aggressive behaviour may be viewed as an adaptation to a sexual environment where the time for reproduction is very short and the probability of meeting a partner is very low. Such an aggressive behaviour may enhance the probability of males catching and copulating with females which are flying through the site. It is significant that the releaser of aggressive attacks, as demonstrated by experimental tests, is the moving individual, not the individual per se. Weather conditions influenced male behaviour, attack distance being significantly and positively related to light intensity. We believe the aggressive pattern observed in *Libellula fulva* cannot be properly classed as territoriality. In this case, in fact, the classical "defence of resources" approach does not work because males did not defend any resources located inside their hypothetical territories. We suggest aggressive interactions may be, in reality, mere attempts to catch females.] Address: Rolando, A. & G. Boano, Dipartimento di Biologia Animale e dell'Uomo, Turin University, Italy

3562. Stav, G.; Kotler, B. P.; Blaustein, L. (2001): Effect of risk of predation on two temporary pool species (*Bufo viridis* and *Culiseta longiareolata*). *Ecological Society of America Annual Meeting, 86th Annual meeting in Madison, WI, August 2001*: 211. (in English). [Verbatim: Green toad (*Bufo viridis*) tadpoles and mosquito larvae (*Culiseta longiareolata*) are highly vulnerable to predation by the dragonfly nymph, *Anax imperator*. We assessed various responses of tadpole and mosquito larva to caged *Anax* in artificial pools. We compared responses in seven treatments (five replicate pools each) of various combinations of presence or absence of: one caged *Anax*, 30 *Bufo* tadpoles and 100 *Culiseta* larvae. Caged *Anax* were fed with 1 tadpole and 3 mosquito larvae once a week. *Culiseta* females oviposited more in pools without *Bufo*. *Bufo* were more prevalent farther from *Anax* in the absence of *Culiseta*, but closer to *Anax* when *Culiseta* were also present. *Culiseta* larvae did not respond spatially to caged *Anax* in the absence of *Bufo*, but when *Bufo* were present, they were more prevalent closer to the predator. The presence of *Culiseta*, but not *Anax*, affected time to and size at metamorphosis, and survival of *Bufo* tadpoles. Both the presence of *Anax* and water turbidity affected color of *Bufo* tadpoles. When *Anax* was present or when water was cloudy, *Bufo* tadpoles were lighter in color. In the lab, lighter colored tadpoles were more vulnerable to *Anax* in clear water, while no difference was found in cloudy water. This study shows the complexity of predation risk on prey species, and its potential effect on temporary pool community.] Address: Blaustein, L., Life Science Department and Mitrani Center for Desert Ecology, Blaustein Institute for Desert Research, Ben-Gurion University, Sede-Boqer Campus, 84990, Is-

rael Community Ecology Laboratory, Institute of Evolution, University of Haifa, 31905, Israel

3563. Steglich, R. (2001): Libellen (Odonata). In: *Arten- und Biotopschutzprogramm Sachsen-Anhalt, Landschaftsraum Elbe. Berichte des Landesamtes für Umweltschutz Sachsen-Anhalt, Sonderheft 2/2001*: 342-352. (in German). [The Federal State of Sachsen-Anhalt, Germany elaborated an extensive study (comprising more than 700 pages) for habitat and species conservation in the floodplain of the River Elbe. Rosmarie Steglich contributed the chapter on Odonata. The odonatalogical importance of the region is outlined, and some consideration on research activities necessary to solve some open questions on the status of rare species are made. *Aeshna affinis*, *A. viridis*, *Lestes barbarus*, *Erythromma viridulum*, *Ophiogomphus cecilia*, *Calopteryx splendens*, *Epitheca bimaculata*, *Stylurus flavipes*, *Gomphus vulgatissimus*, and *Leucorrhinia pectoralis* are commented. In addition, the paper contains a list of unpublished expertises with odonatalogical data, and distribution maps of *A. affinis*, *L. barbarus*, *A. viridis*, *E. viridulum*, *O. cecilia*, and *C. splendens*.] Address: Steglich, Rosmarie, Quittenweg 53, 39118 Magdeburg, Germany

3564. Stevens, L.E.; North, E.; Meretsky, V.J. (2001): Wings and mucus in space and time: Patterns of invertebrate biogeography in Grand Canyon. *Ecological Society of America Annual Meeting, 86th Annual meeting in Madison, WI, August 2001*: 349. (in English). [Verbatim: Taxa with vastly differing vagility may encounter similar dispersal challenges in complex terrain over evolutionary time. Diverse topography and Pleistocene-Holocene climate changes have affected invertebrate biogeography in the Grand Canyon region. Museum collections and published data allowed us to examine the biogeographic role of Grand Canyon as a barrier/filter, corridor, refuge, or null effect. We studied the distribution of landsnails, Odonata, Orthoptera, semi-aquatic Heteroptera, butterflies, and bees. Grand Canyon is a barrier/filter that limits the northward expansion of desert species, and a southern boundary for some Rocky Mountain taxa. The neoregional inner Grand Canyon desert is depauperate and has low levels of endemism, a conclusion supported by the distribution of 31 semi-aquatic Heteroptera, 110 butterflies and skippers, 38 Colorado River chironomid midge species. Butterfly diversity in the desert (42 taxa) is lower than that on either rim (58 and 77 species on the South and North rims, respectively), and that in southern Arizona. The positive relationship between butterfly diversity and elevation is likely an artifact of the small, isolated area of low desert habitat, the evolutionarily brief time (10,000 yr) it has supported desert vegetation, and the long-linear habitat shape. Similar patterns exist among 20 landsnail taxa, with only one endemic snail at one inner canyon spring. However, more than 60 percent of invertebrate taxa are affected by the Grand Canyon as a biogeographic feature.] Address: not stated

3565. Stoks, R.; McPeck, M.A.; Turgeon, J.; Thum, R. (2001): Intercontinental phylogeography of an insect radiation and its ecological implications. *Ecological Society of America Annual Meeting, 86th Annual meeting in Madison, WI, August 2001*: 212. (in English). [Verbatim: Phylogenetic reconstructions provide historical hypotheses for the development of biodiversity in an ecological context. We are investigating the diversification

of one clade of *Enallagma* damselflies on three continents. Based on mtDNA data, this clade appears to have originated in eastern North American lakes containing fish -10 million years ago, with 38 extant North American species. Moreover, about half of these species are derived from the radiation of two lineages in association with the last glacial period (15,000 years ago). Most of these new species are found only in fish lakes, but at least two independent adaptive habitat shifts into fishless waters where large dragonflies are the top predators also occurred. Substantial morphological evolution associated with adapting to dragonfly predation was associated with these habitat shifts. Interestingly, the three Eurasian and one North African *Enallagma* species are derived from an ancestor that split from the North American clade ~900,000 years ago. These four species are also derived from a radiation event that occurred at the same time as the North American radiation. The morphology of one Eurasian species that is distributed from Spain to Russia is very similar to the fishless-lake species of North America, but this species is found in both fish and fishless waters. These data suggest a number of testable hypotheses about differences in the role of fish predation in structuring littoral communities on the two continents.] Address: Stoks, R., Laboratorium voor Aquatische Ecologie, K.U.Leuven, De Beriotstraat 32, B-3000 Leuven, Belgium. E-mail: robby.stoks@bio.kuleuven.ac.be

2002

3566. Akkermans, R.W. (2002): Dragonflies in the Roermond urban area. *Naturhistorisch Maandblad* 91: 103-107. (in Dutch, with English summary). ["A two-year survey of the urban area of the city of Roermond, The Netherlands found 22 species of dragonfly. There are three different water systems within the Roermond urban area: the river Meuse, the river Roer and the Maasnielderbeek brook, each with its own typical dragonfly community. The Meuse system has the smallest number of species, but houses rheophile species like *Calopteryx splendens* and *Platycnemis pennipes*. The Roer, a small river, has a wide spectrum of species, dominated by rheophile species like *C. splendens*, *P. pennipes*, and *Gomphus vulgatissimus*, the latter a red-listed species. The Maasnielderbeek is a brook which was converted to a series of more or less static ponds in the process of urban expansion. These static ponds house the largest numbers of species within the Roermond urban area, including especially species of stagnant water like *C. puella*, *Pyrrhosoma nymphula*, *Aeshna mixta*, and *Sympetrum striolatum*. Finally, the urban area includes a number of garden ponds. These were found to house only the most common species present in the surrounding areas, and added no further species to the survey." (Author)] Address: Akkermans, R.W., Wilhelmialaan 47, NL-6042 EL Roermond, The Netherlands

3567. Alonso-Eguia, L.P.E.; Gonzalez-Soriano, E.; Gutierrez-Yurrita, P.J. (2002): Listado y distribucion de los odonatos de la Cuenca del Rio Moctezuma, Centro-Occidente de Mexico (Insecta: Odonata). *Folia Entomologica Mexicana* 41(3): 347-357. (in Spanish with English summary). ["The Moctezuma basin is located in junction of three North American freshwater ecoregions:

1) Springs in the headwaters of Rio Verde, 2) Rivers and streams in Tamaulipas-Veracruz and 3) Watersheds of the Lerma river system and has been considered as a zone of top priority for the National Board for the knowledge and Use of the Biodiversity (CONABIO). The high deterioration rate of the aquatic ecosystems of the Moctezuma river system make necessary to promote and reinforce this kind of studies to gather information concerning the biological conservation of the ecosystem ecological processes that give biological identity of the area. The main purpose of this study was to know the species of odonata and their distribution in the river Moctezuma Basin. Seventy eight species of Odonata belonging to 36 genera and 10 families were recorded; the family Libellulidae and Coenagrionidae, *Argia* genus in particular, are of special interest due to their great number of species. Four species are new records for Guanajuato, four for Hidalgo and one for San Luis Potosi. *Progomphus belyshevi* is striking for its rarity to this region; *Hetaerina americana* and *Macrothemis pseudimitans* were the more distributed species in the basin. Approximately 70% of the species are limited to one or two localities; 78.5% of Zygoptera and 59.2% of Anisoptera are of netotropical affinity." (Authors)] Address: Gutierrez-Yurrita, P.J., Biología, Facultad de Ciencias Naturales, Universidad Autonoma de Queretaro, Centro Universitario s/n, Cerro de las Campanas, Santiago de Queretaro, QRO, 76010, Mexico; E-Mail: yurrita@sunserver.uaq.mx

3568. Bamnowska, A.; Zawal, A. (2002): Odonate fauna of Binowskie Lake. All-Poland scientific conference "Insect conservation in Poland", Abstracts of papers. *Pol. Tow. Ent., Poznani & Univ. Warmirisko-Mazurski, Olsztyn*: 29. (in Polish). [The odonate fauna of the Binowskie lake near Szczecin in NW Poland is composed of largely common species as *Enallagma cyathigerum* (dominance: > 10%), and *Coenagrion puella*, *C. pulchellum*, *Erythromma najas*, *Ischnura elegans*, and *Platycnemis pennipes* (dominance: each > 5%). No additional species are mentioned.] Address: Polskie Towarzystwo Entomologiczne, Ul Dabrowskiego 159, PO-60-594 Poznan

3569. Barnett, H.K.; Richardson, J.S. (2002): Predation risk and competition effects on the life-history characteristics of larval Oregon spotted frog and larval red-legged frog. *Oecologia* 132(3): 436-444. (in English). ["We conducted an artificial pond experiment to test hypotheses about the effects of competition and non-lethal predator cues on metamorphic characteristics of sympatric Oregon spotted frogs (*Rana pretiosa*) and red-legged frogs (*R. aurora*) in southwestern British Columbia. Tadpoles were exposed to the presence or absence of one another, two density levels and to the presence or absence of predacious odonate larvae (*Aeshna palmata*) isolated in enclosures. In the artificial pond study, *R. aurora* were significantly larger at metamorphosis (12%) and exhibited only slightly longer larval periods when exposed to *Aeshna*. In the presence of *R. pretiosa*, they significantly decreased time to metamorphosis, and were significantly larger at metamorphosis (12%) than those reared alone. *Rana pretiosa* in treatments with *R. aurora* were somewhat larger at metamorphosis when a non-lethal predator was present, and in treatments where *R. pretiosa* were alone with a predator tadpole mass at metamorphosis was smaller than those in the absence of *Aeshna*, but these results were not statistically significant. Both species reduced activity

and moved away from the predator in the presence of an enclosed dragonfly larva in the laboratory. Most tadpole mesocosm experiments have found that the trade-off between size and timing of metamorphosis is extremely important to amphibians, but we suggest that the trade-off discussed in traditional amphibian models may not apply to species like *R. pretiosa* that are exposed to the same grape-limited predators upon reaching metamorphosis." (Authors)] Address: Barnett, Heidy, Department of Forest Sciences, University of British Columbia, 3041-2424 Main Mall, Vancouver, BC, V6T 1Z4 Canada; E-Mail: Heidy.Barnett@ci.seattle.wa.us

3570. Bechly, G.; Sach, V.J. (2002): An interesting new fossil dragonfly (Anisoptera: Libellulidae: "Brachydiplacini") from the Miocene of Germany, with a discussion on the phylogeny of Tetrathemistinae and a fossil list for the locality Heggbach. *Stuttgarter Beiträge zur Naturkunde Serie B (Geologie und Paläontologie)* 325: 1-11. (in English with German summary) ["A new dragonfly species, *Parabrachydiplax miocenica* n. gen. n. sp. (Anisoptera: Libellulidae), is described from the early Middle Miocene of Heggbach in southern Germany. The holotype was collected by the priest J. PROBST in 1865 and represents the earliest record of fossil insect remains from the Upper Freshwater Molasse of Baden-Württemberg. The phylogenetic position of this new genus and species is discussed. It is a very primitive Libellulidae of the subfamily Tetrathemistinae, and can be attributed within the latter taxon to a basal grade within the clearly paraphyletic tribus "Brachydiplacini". The accompanying fauna and flora of *Parabrachydiplax miocenica* n. gen. n. sp. is presented, based on a newly revised fossil list for the locality Heggbach." (Authors)] Address: Bechly, G., Staatliches Museum für Naturkunde, Abt. Paläontologie, Rosenstein 1, D-70191 Stuttgart, Germany. E-mail bechly@gmx.de

3571. Bechly, G.; Ueda, K. (2002): The first fossil record and first New World record for the dragonfly clade Chlorogomphida (Insecta: Odonata: Anisoptera: Araripechlorogomphidae n. fam.) from the Crato Limestone (Lower Cretaceous, Brazil). *Stuttgarter Beiträge zur Naturkunde Serie B (Geologie und Paläontologie)* (328): 1-11. (in English). ["A new dragonfly is described from the Lower Cretaceous limestones of the Crato Formation (Brazil): *Araripechlorogomphus muratai* n. gen. n. sp. (Araripechlorogomphidae n. fam.) which clearly belongs to the chlorogomphid clade within Anisoptera. It is the first fossil record of Chlorogomphida and also the first New World record of this dragonfly group that is now exclusively distributed in East Asia. The phylogenetic and biogeographic implications of this new discovery, are discussed. As consequence of the phylogenetic analysis the new higher taxa Cristotibiata, Paucipostnodalia, Eubrachystigmata, Neobrachystigmata, Paneurypalpidomorpha, Eurypalpidomorpha, and Eurypalpidiformia are introduced. A monotypic family Juracordulidae n. fam. is established for the genus Juracordulia, and the genus *Prohemeroscopus* is transferred from Nannogomphidae to a new monotypic family Prohemeroscopidae n. fam. within Paucipostnodalia as sister-group of Eubrachystigmata." (Authors)] Address: Bechly, G., Staatliches Museum für Naturkunde, Abt. Paläontologie, Rosenstein 1, D-70191 Stuttgart, Germany. E-mail bechly@gmx.de

3572. Bernard, R.; Buczynski, P.; Tonczyk, G. (2002): Status, threats to, and conservation of the odonate fauna

of Poland. All-Poland scientific conference "Insect conservation in Poland", Abstracts of papers. *Pol. Tow. Ent., Poznani & Univ. Warmirisko-Mazurski, Olsztyn*: 8-9. (in Polish). [The summary refers on current activities of Polish odonatologists preparing an distribution atlas of the odonate fauna, on most recent odonatological phenomenes as range extensions of southern species to Poland, and on considerations to focus conservation activities on habitats and specialized species. A German translation of the paper is available from IDF or P. Buczynski.] Address: Polskie Towarzystwo Entomologiczne, Ul Dabrowskiego 159, PO-60-594 Poznani

3573. Biber, E. (2002): Habitat analysis of a rare dragonfly (*Williamsonia lintneri*) in Rhode Island. *Northeastern Naturalist* 9(3): 341-352. (in English). ["*W. lintneri* is a rare dragonfly species restricted to southern New England and some northern states. In 1999, I tested the hypothesis that upland development around wetlands reduces habitat suitability for *W. lintneri* through increased nutrient runoff. I examined 27 wetlands and analyzed water quality and depth data, the composition of aquatic invertebrate assemblages, and land use patterns. Sites where *W. lintneri* was present did not differ in water quality from sites where it was absent (i.e., null sites). However, *W. lintneri* sites had significantly deeper levels of water throughout the summer, were dry for shorter periods of time, and had significantly lower levels of development in the surrounding uplands than did null sites. These results suggest that both hydrologic cycle and upland development are important in limiting the local distribution of this species." (Author)] Address: Biber, E., Yale School of Forestry and Environmental Studies, 370 Prospect Street, New Haven, CT, 06511, USA. E-Mail: eric.biber@aya.yale.edu

3574. Brauckmann, C.; Herd, K.J. (2002): Insekten-Funde aus dem Westfalium D (Ober-Karbon) des Piesberges bei Osnabrück (Deutschland). Teil 1: Palaeoptera. *Osnabrücker Naturwissenschaftliche Mitteilungen* 28: 27-69. (in German with English summary). ["In this first part of a monograph on the hitherto known fossil insects (exclusively Blattodea) from Westphalian D beds of the Piesberg quarry near Osnabrück (Lower Saxony, Germany) the palaeopteran taxa are described. They are distributed among the Palaeodictyoptera (*Homoioptera kortumi* n. sp., *Breyeria brevis* n. sp., *B. bistrata* Brauckmann, 1995, *B. solida* Brauckmann & Herd, 2000, *Hasala inferiorsaxonica* Brauckmann, 1995), Megasecoptera (*Aspidothorax tristrata* n. sp., *A. aestatis* Brauckmann, 1991, *Pyebrodia martinsnetoi* n. gen. n. sp.), Diaphanopteroidea (*Piesbergala leipnerae* n. gen. n. sp.), and Odonatoptera (*Erasipterella piesbergensis* Brauckmann, 1983)." (Authors)] Address: Brauckmann, C., Institut für Geologie und Paläontologie, TU Clausthal, Leibnizstr. 10, D-38678 Clausthal-Zellerfeld, Germany. E-mail: Carsten.Brauckmann@tu-clausthal.de

3575. Buczynski, P.; Czachorowski, S.; Serafin, E.; Szczepanski, W. (2002): Is a nature reserve the optimal place for conservation of aquatic insects?: an example of dragonflies and caddisflies (Odonata, Trichoptera) in the "Kosno Lake" Nature Reserve. All-Poland scientific conference "Insect conservation in Poland", Abstracts of papers. *Pol. Tow. Ent., Poznani & Univ. Warmirisko-Mazurski, Olsztyn*: 30-31. (in Polish). [The nature Reserve 'Kosno Lake' (app. 53.34N 20.19E) was surveyed for its odonate fauna. Within the borders of the reserve,

14 species, and outside the borders 30 species could be recorded. It is concluded that the area of the nature reserve should be expanded. A German translation of the paper is available from P. Buczynski.] Address: Polskie Towarzystwo Entomologiczne, Ul Dabrowskiego 159, PO-60-594 Poznan

3576. Buczynski, P.; Lewandowski, K. (2002): Is a period of 200 years sufficient for dragonfly exploration of a region: exemplified on dragonflies of the North Polish lake district. All-Poland scientific conference "Insect conservation in Poland", Abstracts of papers. Pol. Tow. Ent., Poznan & Univ. Warmirisko-Mazurski, Olsztyn: 31-32. (in Polish). [The paper outlines some milestones in odonatological survey of the Polish lake district. In spite of the fact, that it is explored quite intensively, some periods are nearly without any odonate data. Thus, it will not be possible to analyse the importance of some ancient human exploitation activities on the fauna in a more regional scale, or it will not be possible to analyse the range extensions of some southern species in the last decades. The paper can be understood as an appeal for a long term monitoring of the fauna.] Address: Polskie Towarzystwo Entomologiczne, Ul Dabrowskiego 159, PO-60-594 Poznan

3577. Buskens, R.; Mars, H. de (2002): Attention for moorland pools in Limburg. *Naturhistorisch Maandblad* 91: 195-201. (in Dutch, with English summary). [The ecological value and the variation in moorland pools in terms of their ecohydrological position in the context of the landscape in Limburg, The Netherlands are outlined. Some typical species including the Odonata are briefly annotated.] Address: Buskens, R.; Mars, H. de, Royal Haskoning, Postbus 1754, NL-6201 BT Maastricht, The Netherlands

3578. Buss, D.F.; Baptista, D.F.; Silveira, M.P.; Nesimian, J.L.; Dorville, L.F.M. (2002): Influence of water chemistry and environmental degradation on macroinvertebrate assemblages in a river basin in south-east Brazil. *Hydrobiologia* 481: 125-136. (in English). ["Benthic macroinvertebrate assemblages, water chemistry variables and environmental degradation were investigated in an Atlantic Forest region in Brazil. Seven sites of the Guapimirim river basin were studied during three sampling periods based on the rain regime: end of wet season (May 1998), dry season (August 1998), and wet season (January 1999). Four substrates were collected at each site: sand, stony substrates, litter in pool areas and litter in riffle areas. Relationships between macroinvertebrate assemblages, water chemistry variables and environmental degradation were examined using canonical correspondence analysis (CCA). According to CCA, concentrations of dissolved oxygen and chloride, and the environmental degradation, measured by the Riparian Channel Environment index, exhibited the strongest relationship to macroinvertebrate assemblages. Overall, the loss of community diversity measured by the Shannon Index along the degradation gradient was observed. Some taxa were shown to be sensitive to water pollution, especially among Plecoptera, Trichoptera, Coleoptera and some Ephemeroptera, while others such as Simuliidae, Odonata and molluscs were tolerant to moderate levels of pollutants. The Chironomidae were the only group tolerant to a high level of pollutants and degradation." The habitat is described in detail.] Address: Carron, G., C.P. 250, CH-2002 Neuchâtel, Switzerland

3580. Catling P.M. (2002): Decline of *Gomphus fraternus fraternus* (Odonata: Gomphidae) in Lake Erie. *Great Lakes Entomologist* 34(1) (2001): 1-7. (in English). ["Collections and literature reports indicate that *Gomphus fraternus fraternus* was abundant on the shoreline of Lake Erie prior to 1960, and "tens of thousands" were reported at Long Point Bay. After 1960 there were no reports from the shoreline, although there have been a number of comprehensive studies that have included the shoreline area and a number of Odonata specialists have also visited the Lake Erie shoreline regularly. A survey of portions of the Lake Erie shoreline, including the Long Point Bay area in 1999 and 2000, during the established peak and late peak flight period in southwestern Ontario, did not result in any observations. It is concluded that *G. fraternus* has declined substantially in Lake Erie and is possibly extirpated from the lake. The decline appears to have occurred between 1950 and 1960, and thus approximates the mid-1950s decline of burrowing mayflies in Lake Erie, which has been associated with warm weather oxygen depletion and pollution. Although it may never be possible to precisely determine the cause of the decline of *G. fraternus*, it is likely that a number of factors are involved including climatic warming, pollution, changes to the shoreline, other effects of shoreline development, and introduced species." (Author)] Address: Catling P.M., 2326 Scrivens Drive, R.R. No. 3, Metcalfe, ON, KOA 2P0, Canada

3581. Cordero, A.; Andres, J.A. (2002): Male coercion and convenience polyandry in a calopterygid damselfly. *Journal of Insect Science*, 2:14: 7 pp. ["Copulation in odonates requires female cooperation because females must raise their abdomen to allow intromission. Nevertheless in *Calopteryx haemorrhoidalis haemorrhoidalis* males commonly grasp ovipositing females and apparently force copulations. This has been interpreted as a consequence of extreme population density and male-male competition. We studied this behavior at two sites on a river that had different densities over three years. As predicted, at high densities most matings were forced (i.e. not preceded by courtship), but at low density most were preceded by courtship. Courtship matings were shorter at high density, but density did not affect the duration of forced matings. Females cooperated in forced matings even if they had very few mature eggs. Furthermore, females mated more times if they experienced higher male harassment during oviposition, and at low density second and subsequent matings were more likely to be forced. We interpret these results to mean that females engage in "convenience polyandry", because they gain more by accepting copulation than by resisting males. The results also suggest that females might trade copulations for male protection, because under extreme population density harassment by males is so intense that they

can impede oviposition." (Authors) This paper includes three videos that can be accessed at <http://insect-science.org/2.14>

3583. Dathe, W.; Piechocki, R. (2002): Juan Cristóbal Gundlach - una vida para la ciencia, una vida en 'modestia biblica'. In: Dathe, W. & R.M. González López (Ed.): *Johann Christoph Gundlach (1810-1896). Una naturalista en Cuba / Naturforscher auf Cuba*. ISBN. 3-925347-65-8.: 125-136. (in German and Spanish). [Wilfried Dathe and Rosa María González López edited a book on the Cuban naturalist J.C. Gundlach, born in Marburg, Germany. 11 chapters treat several aspects on the person Gundlach, and on his scientific vita. Special emphasis is given to birds, amphibs, molluscs, and the flora. The book includes a commented translation of his autobiography and a list of his correspondance as far as it was to trace. Regrettably, few information on Gundlach's entomological activities are given. Gundlach co-operated with H. A. Hagen by shipping specimens; Hagen's publications on the Cuban Odonata are based substancially on the collections of Gundlach, and his accompanying descriptions of the dragonflies in life condition (!) (compare: Hagen, H.A. (1867): *Die Neuropteren der Insel Cuba*. *Stettiner entomol. Zeitung* 28: 215- 232; Hagen, H.A. (1868): *The odonata-fauna of the island of Cuba*. *Proceedings of the Boston society for natural history* 11: 289- 294; Hagen, H.A. (1868): *Odonaten Cubas*. *Stettiner entomol. Zeitung* 29: 274-287). In addition, Gundlach published a comprehensive work on the Odonata of Cuba by himself (Gundlach, J.C. (1888): *Contribución á la entomología Cubana*. *Neurópteros*. Habana, Alvarez & Co. 2: 189-281). This publication was failed to notice for long years. P.P. Calvert traced it, and commented critically on Gundlach's publication (see: Calvert, P.P. (1919): *Gundlach's work on the odonata of Cuba, a critical study*. *Transactions of the American entomological society* 45: 335- 396; Calvert, P.P. (1921): *On Gundlach's work and on Enallagma pollutum and E. vesperum*. *Ent. news* 32: 32). In a chapter (pages 125-136) the correspondance of Gundlach with Carl Robert von Osten Sacken, Herman August Hagen, and Philip Reese Uhler is outlined. This interesting book - priced 24,50 Euro - can be obtained by W. Dathe.] Address: Dathe, W., Hegelstr. 73, D-06114 Halle/Saale, Germany. E-mail: wilfried.dathe@gmx.de

3584. Dolny, A.; Misztka, A.; Parusel, J. (2002): Dragonfly conservation perspectives in the Czech and Polish parts of the Upper Silesia. All-Poland scientific con-

ference "Insect conservation in Poland", Abstracts of papers. *Pol. Tow. Ent., Poznani & Univ. Warmirisko-Mazurski, Olsztyn*: 33-34. (in Polish). [The odonate fauna of the Czech-Polish border region is analyzed in terms of common conservation measures for the odonate fauna. Two main data pools exist: one from the beginning of the 20th century, and one resulting from studies between 2000 and 2002. It is concluded that most nature reserves (n=189) in the region are insufficient to protect Odonata. Only 23 nature reserves aim to conserve aquatic habitats. The restoration of water bodies with the rare and threatened *Stratiotes aloides* would give the opportunity to re-establish *Aeshna viridis* in the region.] Address: Available from *Pol. Ent. Soc. 3586. Evans, H.E. (2002): A review of prey choice in Bembicine sand wasps (Hymenoptera: Sphecidae). *Neotropical Entomology* 31(1): 1-11. (in English). ["The prey of 132 species of Bembicini (Hymenoptera) that have been studied is reviewed. About three quarters of the species prey on Diptera, and it is believed that fly predation is ancestral in the group. Eleven species make occasional or regular use of other insects as prey in addition to Diptera (Lepidoptera, Hymenoptera, Neuroptera, Odonata, and/or Homoptera), while 21 species of five genera prey on insects of these same five groups with no use of Diptera. It is hypothesized that this represents an evolutionary progression, whereby populations have experienced shortages of dipterous prey in the past and have broadened their sensory focusing to include other groups of flying insects. Behavior initially learned has, over time, been reinforced genetically to produce the currently observed radiation in prey choice within the group." (Author)] Address: Evans, H.E., Dept. Bioagricultural Sciences and Pest Management, Colorado State University, Fort Collins, CO, 80523-1177 USA

3587. Fagan, W.F.; Siemann, E.; Mitter, C.; Denno, R.F.; Huberty, A.F.; Woods, H.A.; Elser, J.J. (2002): Nitrogen in insects: Implications for trophic complexity and species diversification. *American Naturalist* 160(6): 784-802. (in English). ["Disparities in nutrient content (nitrogen and phosphorus) between herbivores and their plant resources have lately proven to have major consequences for herbivore success, consumer-driven nutrient cycling, and the fate of primary production in ecosystems. Here we extend these findings by examining patterns of nutrient content between animals at higher trophic levels, specifically between insect herbivores and predators. Using a recently compiled database on insect nutrient content, we found that predators exhibit on average 15% greater nitrogen content than herbivores. This difference persists after accounting for variation from phylogeny and allometry. Among herbivorous insects, we also found evidence that recently derived lineages (e.g., herbivorous Diptera and Lepidoptera) have, on a relative basis, 15% - 25% less body

nitrogen than more ancient herbivore lineages (e.g., herbivorous Orthoptera and Hemiptera). We elaborate several testable hypotheses for the origin of differences in nitrogen content between trophic levels and among phylogenetic lineages. For example, interspecific variation in insect nitrogen content may be directly traceable to differences in dietary nitrogen (including dilution by gut contents), selected for directly in response to the differential scarcity of dietary nitrogen, or an indirect consequence of adaptation to different feeding habits. From some functional perspectives, the magnitude rather than the source of the interspecific differences in nitrogen content may be most critical. We conclude by discussing the implications of the observed patterns for both the trophic complexity of food webs and the evolutionary radiation of herbivorous insects." (Authors). Predatory Odonata (n=2) were tested against herbivory Ephemeroptera (n=3) ((tab. 1). Within ordinal groups, mean predator N content always exceeded the corresponding herbivore mean. The difference between Odonata and Ephemeroptera was 2.20%. The mean within-order difference was 1.34%. More details may be available at <http://www.nceas.ucsb.edu/ecostoichiometry>.] Address: Fagan, W.F., Department of Biology, University of Maryland, College Park, Maryland 20742, USA. 3589. Feiber, A.L.; Rangarajan, J.; Vaughn, J.C. (2002): The evolution of single-copy Drosophila nuclear 4f-rnp genes: Spliceosomal intron losses create polymorphic alleles. *Journal of Molecular Evolution* 55(4): 401-413. (in English). ["This study provides the first report in which spliceosomal intron losses within a single-copy gene create functional polymorphic alleles in a population. 4f-rnp has previously been shown to be a nuclear gene that is localized on the X chromosome in *D. melanogaster* and to have eight short spliceosomal introns. An insect species survey was done via polymerase chain reaction (PCR) amplification and sequencing of a 1028-bp gene fragment spanning introns 4-8, which are located in the 3' half of the gene. The results show that 4f-rnp and (thus far) introns 7 and 8 are at least as old as order Odonata, an early-diverging insect line. Unexpectedly, several species within the dipteran family Drosophilidae were found to contain two differently sized 4f-rnp gene sequence variants, owing to precise inframe intron losses. Results of single-male *D. melanogaster* PCR analyses show that the two gene size variants are allelic and that the intron loss mechanism appears to be biased toward the 3' end of the gene. A stable potential stem-loop has been identified in *D. melanogaster*, predicted to fold the 4f-rnp mRNA 3' terminus into a natural primer for subsequent reverse transcription into cDNA. When results are displayed in a phylogenetic context, multiple independent intron loss events are identified. These observations support a model in which frequently occurring cDNAs have led to numerous independent intron losses via homologous recombination/gene conversion during 4f-rnp gene evolution. The results provide insights into the evolution of intron loss and may lead to improved understanding of

the dynamics of this process in natural populations." (Authors)] Address: Vaughn, J.C., Dept of Zoology, Miami University, Oxford, OH, 45056, USA. E-Mail: vaughnjc@muohio.edu

3590. Fleck, G. (2002): Contribution à la connaissance des odonates de Guyane française. Notes sur les genres *Epigomphus* Hagen, 1854 et *Phyllocycla* Calvert, 1948 (Anisoptera, Gomphidae). *Bull. Soc. Entomol. France* 107: 493-501. (in French, with English summary). ["The larva of *Epigomphus hylaeus* Ris, 1916, and the true larva of *Phyllocycla neotropica* Belle, 1970, are described and illustrated for the first time. The differences with the other known larvae of these genera are listed. For both genera, a key in French and in English is given to separate the unambiguously known ultimate instars larvae. The previously unknown female of *Phyllocycla neotropica* is briefly described and illustrated. A reared larva of *Phyllocycla modesta* Belle, 1970, yielded a female showing a thoracic color pattern different from that of the allotype described by Belle (1970)."] (Author)] Address: Fleck, G., Lab. 3591. Fleck, G.; Nel, A. (2002): The first isophlebioid dragonfly (Odonata: Isophlebioptera: Campterothlebiidae) from the Mesozoic of China. *Palaeontology* 45(6): 1123-1136. (in English). ["*Bellabrunetia catherinae* gen. et sp. nov., the first Chinese Mesozoic isophlebioid dragonfly, is described. This fossil is the first known Isophlebioptera with well-preserved body structures, demonstrating that the fore- and hindwings are of very different size and shape in Campterothlebiidae, and that the female Campterothlebiidae had an endophytic way of oviposition, unlike the Isophlebiidae." (Authors)] Address: Fleck, G., Laboratoire d'Entomologie and CNRS UMR 8569, Muséum National d'Histoire Naturelle, 45 rue Buffon, F-75005, Paris, France. E-Mail: fleck@mnhn.fr, anel@mnhn.fr

3592. Fleck, G. (2002): Une larve d'Odonate remarquable de la Guyane française, probablement *Lauro-macromia dubitalis* (FRASER, 1939) (Odonata, Anisoptera, 'Corduliidae'). *Bulletin de la Société Entomologique de France* 107(3): 223-230. (in French, with German and English summary). [From French Guyana, a last instar larva of the neotropical "cordulid" *Lauro-macromia* Geijskes, 1970 - probably *L. dubitalis* - is described in detail. The "larvae show well-developed lateral spines on abdominal segments 3 to 9 which is unusual for cordulegastrid-like or libellulid-like larvae. In the libellulid-like larvae, the lateral spines are generally confined on segments 8 and 9. Traditionally the genus *Lauro-macromia* was considered to be a member of the Gomphomacromiinae sensu Davis & Tobin (1985). The features of the larva clearly demonstrate that the genus *Lauro-macromia* cannot be considered as a Gomphomacromiidae sensu Carle (1995) because of the presence of raptorial setae on the labial palp which are a clear synapomorphic character to the "Macromiid-Cordulid-Libellulid-Complex" sensu Carle, 1995 (= *Valvulida* sensu Lohmann, 1996) (= *Trichodopalpida* sensu Bechly, 1996)."] (Author)] Address: Fleck, G., Lab. Ent. Mus. Natn. Hist. Nat., 45 rue Buffon, F-75005 Paris, France. E-mail: fleck@mnhn.fr

3593. Geraeds, R.P.G.; Schaik, V.A. van (2002): Observations on the distribution and ecology of the Club-

tailed dragonfly (*Gomphus vulgatissimus*) along the river Roer. *Natuurhistorisch Maandblad* 91: 113-118. (in Dutch with English summary). [*G. vulgatissimus* has always been a rare species in the province of Limburg, The Netherlands. "During an intensive inventory in 2000 and 2001, however, 1597 exuviae of this species were found along the river Roer. Observations on the adult dragonflies were also recorded. The species can be found along the entire river. The greatest densities of exuviae were found between Herkenbosch and Roermond. Here, the larvae find ideal conditions in slow-flowing muddy parts of the river. Most larvae emerge vertically and close to the waterline (0-0.5 m). They seem to prefer emerging among the vegetation. The average length of the exuviae was 29.5-30mm." (Authors)] Address: Geraeds, R., Julianalaan 46, NL-6042 JH Roermond, The Netherlands

3594. Gibbons, L.K.; Reed, J.M.; Chew, F.S. (2002): Habitat requirements and local persistence of three damselfly species (Odonata: Coenagrionidae). *Journal of Insect Conservation* 6(1): 47-55. (in English). ["Habitat requirements and population persistence were investigated in three damselfly species, all coastal plain pond specialists: *Enallagma recurvatum*, *E. laterale*, and *E. pictum*. Because of geographic restriction, two are of special concern to conservation, *E. recurvatum* and *E. laterale*. We surveyed more than 70 ponds on Cape Cod, Massachusetts, and collected adult presence-absence data during the summers of 1999 and 2000. We achieved a detection rate approaching 100% for each species by visiting each pond up to three times. We looked for relationships between the presence of each damselfly species and presence of specific aquatic vegetation, the presence of the other *Enallagma* species, and the number of ponds within various distances of the 72 surveyed ponds. Using stepwise logistic regression, we found the following significant associations: *E. recurvatum* with the rush *Juncus militaris*; *E. laterale* with water lilies (*Nuphar variegatum* and *Brasenia schreberi*) the damselfly *E. pictum*, and the number of ponds within 2 km; and *E. pictum* with the water lily *Nymphaea odorata*, the damselfly *E. laterale*, and the number of ponds within 1.5 km and 2.5 km. Presence-absence data were used to calculate turnover and local extinction rates for each species between the two years. *E. recurvatum*'s turnover and local extinction rates (33.3% and 41% respectively) were much higher than either *E. laterale* (9.8%, 11.5%) or *E. pictum* (7.7%, 10%). These results suggest that *E. recurvatum* occurs in a metapopulation, and that patch colonization rates might be important to local population persistence." (Authors)] Address: Reed, J.M., Dept Biol., Tufts Univ., Medford, MA 02155, USA. E.mail: mreed@tufts.edu

3595. Goldschmid, U.; Grotzer, C. (2002): Anlage und Management eines Teiches als ökologische Ausgleichsmaßnahme: Das Tritonwasser auf der Wiener Donauinsel. *Denisia* 3: 25-45. (in German with English summary). ["In 1989 the Department of Water Res decided to set up an about 2 ha large pond. It was to fulfil exclusively ecological functions and to serve as a further stepping-stone in a chain of humid biotopes. Special consideration was given to the demands amphibious animals, water- and reed-birds and dragonflies make on a water body. The design of the pond and its environment were derived from the ecological requirements as: well structured shoreline with bays, islands

and peninsulas; flat riparian zones; deep water zones which will not freeze; high structural diversity by initial plantings of submerged and emergent vegetation. The construction work was carried out during winter of 1989/90. The basin of the pond was sealed with a 30 cm-thick layer of clay. The substratum ranges along the gradient from sands to coarse gravel. The gradients of the slopes reach a maximum of 1:2, but are at an average of 1:5 to 1:10. Parts of the pond are separated by gravel ridges into several individual sections, which get an individual character from a hydrologic and faunistic point of view. The pond was filled via a feeding pipeline from the New Danube. Initial plantings were carried out, mainly with a variety of marsh and aquatic plants. These endemic plants were taken from several detention reservoirs of Vienna's rivers. The succession processes and colonization by animals and the increase of plants are subjected to a scientific long-term monitoring project." ISBN 90-5107-031-4.] Address: not stated

3598. Houston, W.A.; Duivenvoorden, L.J. (2002): Replacement of littoral native vegetation with the ponded pasture grass *Hymenachne amplexicaulis*: Effects on plant, macroinvertebrate and fish biodiversity of backwaters in the Fitzroy River, Central Queensland, Australia. *Marine & Freshwater Research* 53(8): 1235-1244. (in English). ["Changes in plant and macroinvertebrate communities were found following replacement of extensive zones of floating-attached/submergent native vegetation within Fitzroy River backwaters by the major environmental weed *Hymenachne amplexicaulis* (Poaceae). Impacts of *H. amplexicaulis* on native littoral flora and fauna (macroinvertebrates and fish) were assessed by comparing three sites previously supporting native vegetation and now invaded by *H. amplexicaulis* with nearby stands of native backwater vegetation. Plant biomass of *Hymenachne* plant beds was 30-fold greater than native plant beds, whereas plant species diversity (richness) was significantly less. Macroinvertebrate communities of *Hymenachne* beds were significantly lower in abundance of insect orders Ephemeroptera, Hemiptera and Odonata, while Coleoptera were more abundant in *Hymenachne* beds. Non-metric multidimensional scaling ordination of macroinvertebrate family abundance and composition data showed that

Hymenachne plant beds had a different assemblage to that in native plant beds. In common with other studies of weed invasions, an increased abundance of some vertebrate fauna was observed (in this case an introduced fish species *Xiphophorus maculatus* comprised 75% of fish captured in Hymenachne beds compared with 0% in native plant beds). Change in vegetation structure was implicated as an important factor influencing macroinvertebrate and fish faunal composition, and with potential to impact on waterbird habitat values of wetlands." (Authors)] Address: Houston, W.A., Centre for Environmental Management, Central Queensland University, Rockhampton, QLD, 4702, Australia. E-Mail: w.houston@cqu.edu.au

3599. Huguët, A.; Nel, A.; Martínez-Delclos, X.; Bechly, G.; Martins-Neto, R. (2002): Preliminary phylogenetic analysis of the Protanisoptera (Insecta: Odonatoptera). *Geobios* 35(5): 537-560. (in English). ["The Permian suborder Protanisoptera (Insecta: Odonatoptera) is revised and a new phylogenetic hypothesis proposed after analyses based on wing venation and different outgroups. After our study the families Camptotaxineuridae and Kaltanoneuridae are excluded from the Protanisoptera. After a new phylogenetic analysis, the family Permaeschnidae is redefined and the families Pholidoptilidae, Polytaxineuridae, Callimokaltaniidae and Hemizygopteridae are restored, as already proposed for the latter three families by Bechly (1996). The new genus *Proditaxineura* is described. The genus *Gondvanoptilon* ROSLER et al., 1981 is excluded from the Meganisoptera: Erasipteridae and re-included in the Permaeschnidae, as already proposed by Bechly (1998). *Permaeschna proxima* MARTYNOV, 1931 is considered as a junior synonym of *Permaeschna dolloi* MARTYNOV, 1931. *Pholidoptilon camense* ZALESSKY, 1931 is excluded from *Permaeschna* MARTYNOV, 1931 and the genus *Pholidoptilon* ZALESSKY, 1931 is restored. *Ditaxineurella stigmalis* MARTYNOV, 1940 is excluded from the Hemizygopteridae and considered as a Protanisoptera Incertae sedis." 3602. Knötzsch, G. (2002): Das Auftreten mediterraner Libellenarten im Eriskircher Ried. *Naturschutz zwischen Donau und Bodensee* 1: 37-42. (in German). [Baden-Württemberg, Germany; a monitoring of Odonata starting in the end of the 1980th proves that so called mediterranean species as *Aeshna affinis*, *Crocothemis erythraea*, and *Sympetrum fonscolombii* meanwhile belong to the characteristic and permanent fauna of the area. It can be assumed that global warming is one of the main reasons of the range extensions of these species. The author outlines in some detail the ecological factors responsible for the occurrence of *A. affinis* in the area: this species depends on the high flood of lake Constance, and builds up large populations in a year with high flood, while it may lack in dry summers. Records of *Sympetrum meridionalis* in August 2002 are very remarkable. In addition, records of *Lestes barbarus*, *C. erythraea*, and *S. fonscolombii* are reported in detail, and a check-list comprising of 45 odonate species is added. The Eriskirchener Ried is definitely a "Prime Dragonfly Area" in (Western) Europe.] Address: Knötzsch, G., Friedrichstr. 44, D-88045 Friedrichshafen, Germany.

3603. Koperski, P. (2002): Factors determining diversity in diet composition: multivariate analysis of a guild of epiphytic predators. *Arch. Hydrobiol.* 155(2): 291-314. (in English). ["The diet composition of five species of epiphytic predators (the larval damselfly *Enallagma cyathigerum*, larval midge *Ablabesmyia monilis*, larval caddisfly *Cyrnus flavidus* and leeches *Erbobdella octoculata* and *E. nigricollis*), inhabiting *Stratiotes aloides* in the shallow littoral of three Polish lakes, was analysed using multivariate methods. The gut contents of individuals living in experimental mesocosms were also analysed to test the behavioural effects of the stimuli released by larger predators - fish and aquatic insects. The main aims of the study were: to determine the most important interactions between particular members of the guild of epiphytic predators, to explain interactions between the above and their feeding resources and to characterize the effects of experimentally simulated predatory pressure. A further aim was also to test if the diversity in dietary composition caused by intrinsic, species-specific feeding preferences is higher or lower than that caused by anti-predator changes in their feeding behaviour. To design the data matrix, the dietary composition of each of 595 individuals was characterised by 28 variables, designing at the numbers or percentage of prey taxa and prey ecological groups as well as the cumulative metrics and indices. [...] Individual dietary composition has customarily been seen as depending more markedly on the presence of stimuli from larger predator than on taxonomic specifics. The dietary compositions of the three insect species studied were more similar in natural conditions than in experimental habitats. The dietary composition of *E. nigricollis* was more distinct from the diets of the other species, and significantly different even from that of the congeneric species *E. octoculata*. Diets of leeches diverged more significantly in various feeding habitats than those of insect larvae. Moreover, the diversity to the dietary compositions of particular species feeding in natural lake conditions was lower than that to the composition noted for conspecifics feeding in different habitats." (Author)] Address: Koperski, P., Department of Hydrobiology, Institute of Zoology, Warsaw University, Banacha 2, 02-097 Warszawa, Poland. E-mail: koper@hydro.biol.uw.edu.pl

(in German with English summary). [A comparison is made between the 1986 and 1996 odonate assemblages of the abandoned gravel pit, canton Basel-Landschaft, Switzerland. The alterations are probably due to management measures, aiming at the re-institution of some early succession stage habitats.] Address: Bauer-Stingelin, Fraumattstr. 51, CH-4410 Liestal, Switzerland
- 3606.** Laurila, A.; Pakkasmaa, S.; Crochet, P.-A.; Merila, J. (2002): Predator-induced plasticity in early life history and morphology in two anuran amphibians. *Oecologia* 132(4): 524-530. (in English). ["Predation pressure during early life stages is often high, but few studies have examined antipredator responses at these stages. We studied the effects of an egg predator (leech, *Haemopsis sanguisuga*) and two tadpole predators (dragonfly larvae, *Aeshna* spp.; and three-spine stickleback, *Gasterosteus aculeatus*) on the timing of hatching and morphology of hatchlings and young tadpoles in two anuran amphibians (*Rana arvalis* (RA) and *R. temporaria* (RT)) in a factorial laboratory experiment. We also compared the responses of two geographically separated RA populations on the Baltic island of Gotland and in Uppland on the Swedish mainland. We found inconsistent evidence for the predictions that the presence of an egg predator induces earlier hatching, and the presence of a larval predator delays hatching. RT hatched later in the presence of stickleback than in the control treatment, but RA hatched earlier, less developed and at smaller size in the leech, dragonfly, and stickleback treatments. There was no indication of predator-induced morphology in hatchlings of either of the species. However, young RA tadpoles had shorter tails and deeper bodies in the stickleback treatment and RT had shorter tails in the leech, dragonfly and stickleback treatments. Irrespective of treatment, RA from Gotland hatched with relatively longer bodies than Uppland individuals and had relatively deeper and short tails as young tadpoles. Our results highlight the diversity of induced responses to predators in anuran amphibians: predator presence affects the timing of hatching and morphology of young tadpoles, but these responses vary depending on the species and predator considered." - 3612.** Mitra, T.R. (2002): Geographic distribution of Odonata (Insecta) of eastern India. *Memoirs of the Zoological Survey of India* 19(1): 208 pp. (in English). [294 odonate species and subspecies are known to occur in eastern India. The geographic scope of eastern India

includes the fauna of the states Arunachal, Pradesh, Assam, Bihar, Manipur, Mizoram, Nagaland, Orissa, Sikkim, Tripura, and West Bengal. The monograph compiles the available odonotological information, contains keys for the identification of the species, their variations from the reference collections present in the Zoological Survey of India, compiles descriptions available in the Fauna of British India volumes, and outlines the geographical distribution in detail. "It also embodies description of new species of *Calicnemia* and *Gomphidia* and five indeterminate species, females of *Agriocnemis nana*, *Indothemis limbata limbata*." This is a little bit obscure, because *C. sudhaae* and *G. leonoraee* were described in Mitra, T.R. (1994): Observations on the habits and habitats of adult dragonflies of eastern India with special reference to the fauna of West Bengal. Rec. zool. Survey India (Occ. pap.) 166: 1-40. The indeterminate taxa are *Crocothemis indica* Sahni, 1964 = *C. servillia* (Drury, 1773), *Crocothemis misrai* Bajjal and Agarwal, 1956 = *Trithemis aurora* (Burmeister, 1839), *Orthetrum ganeshii* Mehrotra, 1961 and *O. chandrabali* Mehrotra, 1961 = *Orthetrum triangulare* (Selys, 1878), and *Ictinogomphus distinctus* Ram (1985) = probably a synonym of *Ictinogomphus rapax* (Rambur, 1842), *Bradinyoga saintjohanni* Bajjal & Agarwal, 1955 = *Bradinyoga saintjohanni geminata* (Rambur, 1842). The geographic distribution of the taxa is discussed in detail. A bibliography and an index contribute significantly to this valuable and commendable publication.] Address: Mitra, T.R., "M" Block, New Alipore, Kolkata 700 053, India

3613. Monnerat, C.; Gonseth, Y. (2002): Jahresbericht 2001. Odonata 2000. Nachrichten des Schweizer Zentrum für die Kartographie der Fauna 23: 6-7;-23-24. (in German and French). [In the framework of preparing the Red List of endangered Swiss Odonata, trends of population development of selected species were analyzed using a statistic program. The results were compared with the opinion and field experiences of dragonfly experts. A special survey of the rare *Brachytron pratense* was realized to check the trends. It is concluded that the opinion of the experts fits best to the reality. In addition, some so called data sheets on *Ceragrion tenellum*, *Sympetma paedisca*, *Gomphus similimus*, *Leucorrhinia albifrons*, *L. caudalis*, *L. pectoralis*, *Calopteryx virgo*, *C. splendens*, *Sympetrum flaveolum*, *Lestes dryas*, *L. virens*, *Eitheca bimaculata*, *Coenagrion mercuriale*, and *Ophiogomphus cecilia* were prepared for publication in 2002. Furthermore, an update of the dragonfly atlas of Switzerland was discussed with the experts, and its scope was defined.] Address: Monnerat, C., Centre suisse Cartogr. Faune, Terreaux 14, CH-2000 Neuchatel, Switzerland. E-mail: christian.monnerat@cscf.unine.ch

3614. Mustow, S.E. (2002): Biological monitoring of rivers in Thailand: Use and adaptation of the BMWP score. *Hydrobiologia* 479: 191-229. (in English). ["The performance of the BMWP biotic score, which is based on macroinvertebrates (including Odonata), in accurately classifying 23 sites on the River Ping system in northern Thailand, was assessed through comparison with physical and chemical data. Sites were located on the main River Ping, a highly polluted tributary (Kha Canal), a relatively unpolluted tributary (River Taeng) and an upland stream tributary system (River Klang). Data were collected between December 1990 and September 1993. The purpose of the research was to determine

whether the BMWP score, originally developed in the U.K., could be employed successfully in Thailand and potentially also in other subtropical and tropical developing countries. Biological monitoring techniques such as the BMWP score are low-tech, rapid means of assessing water quality, and involve significantly lower financial costs than chemical monitoring techniques. The BMWP score was capable of distinguishing between sites that were heavily impacted by organic pollution and relatively unpolluted sites, and showed some potential to identify lower levels of pollution. The overall performance was considered to be similar to that recorded in the U.K. It was noted during the study that several of the taxa used in the BMWP score were absent in Thailand and that other taxa were present that would potentially be useful indicators. The BMWP score was therefore modified by removing 15 taxa not present in Thailand and adding 11 replacement taxa. Also, in the modified score, 6 sets of families were combined due to taxonomic difficulties and 7 odonatan families were allocated lower scores. The modified procedure, named the BMWPTHAI score, did not significantly alter the way in which sites were classified, but was easier to use. There is strong potential for application of the BMWPTHAI score in Thailand and other developing countries, although some further testing is first recommended." 3615. Muzlanov, Yu.A. (2002): Chronological dynamics of the distribution of wing venation anomalies in intrapopulation groups of *Calopteryx splendens* Harr. damselflies. *Ekologiya* (Moscow) 3: 209-214. (in Russian with English summary). ["The long-term dynamics of the number of full (normal) veins, venation anomalies, and linear parameters of the wings of *C. splendens* males from neighboring population groups were analyzed. Correlation analysis showed that some of the anomalies may emerge in addition to the full veins, whereas others are formed instead of them. The demoiselles from even-year generations had a significantly greater number of developmental abnormalities. This may have been caused by the sharp increase in the radiation level in the summer of 1986 due to the Chernobyl accident, which could have resulted in significant hereditary disorders manifested in the succession of generations of this genetic group. The emergence of venation abnormalities in demoiselle wings is a stochastic process, strengthened by both environmental and genetic stress. These anomalies may be considered as markers of the stability of ontogenetic processes, which greatly reflect the specific genotypic traits of individuals within a population. The analysis of average values for venation abnormalities in demoiselle wings is a more precise instrument for assessing ontogenetic stability than the levels of fluctuating asymmetry and general phenotypic variance." (Author)] Address: Muzlanov, Yu.A., Zarevskaya Secondary School of General Education, Zarya, Ryazan Russia

3616. Negishi, J.N.; Inoue, M.; Nunokawa, M. (2002): Effects of channelisation on stream habitat in relation to a spate and flow refugia for macroinvertebrates in northern Japan. *Freshwater Biology* 47(8): 1515-1529. (in English). ["1. The effects of channelisation on macroinvertebrates were examined in relation to a spate and flow refugia. Habitat components that can function as flow refugia were identified in a small, low-gradient

stream in northern Hokkaido, Japan. 2. Macroinvertebrates and their habitat characteristics (depth, current velocity and substratum) were sampled and measured in natural and channelised sections on three occasions: before, during and immediately after a spate. For macroinvertebrate sampling and habitat measurements, five (riffle, glide, pool, backwater and inundated habitats) and three (channelised-mid, channelised-edge and inundated habitats) habitat types were classified in the natural and channelised section, respectively. 3. The rate of velocity increase with discharge was compared among habitat types to determine which habitat types were less affected by increased discharge. The rate was the highest in riffles followed by glides and channelised-mids. Backwaters maintained low current velocity even at high flow. In addition, current velocity in both natural and channelised inundated habitats was low relative to other habitat types during the spate. 4. Through the spate, total density of macroinvertebrates in channelised-mids and taxon richness in both channelised-mids and edges decreased. In the natural section, however, such a significant decrease was not found except for taxon richness in pools. This indicated that the spate had a greater impact on assemblages in the channelised section. Riffle assemblages exhibited a rapid recovery immediately after the spate, suggesting the existence of flow refugia in the natural section. Among the habitat types we examined, backwaters and inundated habitats appeared to have acted as flow refugia, because these habitats accumulated macroinvertebrates during the spate. 5. The lower persistence of the macroinvertebrate assemblage in the channelised section was attributable to the lower availability of flow refugia such as backwaters and inundated habitats. Our results emphasised the importance of considering flow fluctuations and refugia in assessing the effects of channelisation. In addition, the lateral heterogeneity of stream channels should be considered in stream restoration and management." (Authors) "Davidius" ist listed in table 4.] Address: Negishi, J.N., Dept Forest Sci., Fac. Agriculture, Hokkaido Univ., Sapporo, Japan. E-mail: artp1496@nus.edu.sg

3617. Nel, A.; Huguet, A. (2002): Revision of the enigmatic Upper Carboniferous insect *Campyloptera eatoni* Brongniart, 1893 (Insecta: Odonatoptera). *Organisms Diversity & Evolution* 2(4): 313-318. ["*Campyloptera eatoni* Brongniart, 1893, the type species of the type genus of the Upper Carboniferous family Campylopteridae Handlirsch, is redescribed. It is not a Megasecoptera as previously supposed, but an Odonatoptera with a specialized wing venation. Although it has a more basal position than the Meganeuridae because of the absence of any nodal or subnodal structure, it has acquired a simple vein MA and a widening area between MP and CuA, convergently with the highly derived Discoidalia clade that includes the modern Odonata. A new diagnosis is given for Campylopteridae and its type genus, *Campyloptera* Brongniart. *Campylopteroidea* Rohdendorf, 1962 falls as a new junior synonym under Odonatoptera Martynov, 1932." 3618. Nokkola, A.; Laukkanen, A.; Nokkola, C. (2002): Mitotic and meiotic chromosomes in *Somatochlora metallica* (Cordulidae, Odonata). The absence of localized centromeres and inverted meiosis. *Hereditas* 136(1): 7-

12. (in English). ["Spermatogonial metaphase chromosomes were examined in two dragonfly species, *Somatochlora metallica* (Cordulidae) and *Aeshna grandis* (Aeshnidae), and the behaviour of male meiotic chromosomes was studied in *S. metallica*. Both in *S. metallica* and *A. grandis* the male mitotic metaphase chromosomes from cells treated with colchicine consisted of two; equidistantly aligned chromatids, showing no primary constriction. In meiosis the chromosomes of *S. metallica* males showed telokinetic activity during the first meiotic division, and kinetic activity was restricted in the middle parts of chromosomes during the second division. The kinetic behaviour of the chromosomes both in mitosis and meiosis showed that they were holocentric. One chiasma arises interstitially in each bivalent in *S. metallica* male meiosis. The chiasmata retain their interstitial position at metaphase I and do not terminalize. At metaphase I bivalents co-orient with homologous telomere regions towards the opposite poles. Thus genuine dyads segregate at the first anaphase. Meiosis in these male dragonflies is thus pre-reductional or conventional, not post-reductional or inverted, as has been previously proposed." 3621. Oo, T.T.; Storch, V.; Becker, N. (2002): Studies on the bionomics of *Anopheles dirus* (Culicidae: Diptera) in Mudon, Mon State, Myanmar. *Journal of Vector Ecology* 27(1): 44-54. (in English). ["This study examined some environmental factors influencing the larval habitats of *Anopheles dirus* (breeding in wells) in Mudon, Myanmar, from May 1998 to March 2000. The lar-

val/pupal density was found to be directly proportional to rainfall and indirectly proportional to the well water level. Shade, vegetation and debris on the surface of well water were important factors influencing the abundance of the aquatic stages of *An. dirus*. Salinity had an inverse correlation with the larval and pupal density. Other mosquito species associated with *An. dirus* were identified. Important predators of the mosquito larvae were larvivorous fish, damselfly and dragonfly nymphs. All wells examined were lined with lateritic rocks. Chemical analysis of water samples from wells was conducted." (Authors)] Address: Becker, N., German Mosquito Control Association/KABS, Ludwigstr. 99, 67165, Waldsee, Germany Germany

3622. Pilgrim, E.M.; Roush, S.A.; Krane, D.E. (2002): Combining DNA sequences and morphology in systematics: testing the validity of the dragonfly species *Cordulegaster bilineata*. *Heredity* 89: 184-190. (in English). [Morphological techniques are combined with DNA sequences to determine the taxonomic status of *C. bilineata*. The latter and *C. diastatops* are very similar in morphological features, therefore the status of *C. bilineata* as a valid species is in question. Here, male morphological measurements and internal transcribed spacer 1 (ITS-1) sequences of rDNA are compared between the two taxa. "The male hamule measurements (where copulation occurs) show little difference between the taxa in question, but the anal appendage measurements (where the 6 first contacts the female) show marked divergence between the two taxa. Cluster analysis with these anal appendage measurements correctly assigns almost all individuals measured into their respective taxon. PCR amplification products of ITS-1 display a -50 bp size difference between *C. bilineata* (n = 4) and *C. diastatops* (n = 5) regardless of collection site. Sequence data or these amplifications show 51 bp missing in one locus in the ITS-1 of *C. bilineata* relative to *C. diastatops*. A lone population of *C. diastatops* from Wisconsin has three individuals with ITS-1 products that match the size of both *C. bilineata* and *C. diastatops*. One individual from this population appears to yield two ITS-1 amplification products that match both *C. bilineata* and *C. diastatops*. Although this population may be evidence for hybridization between the 2 taxa, such hybridization is not necessarily sufficient to disqualify the validity of a separate species designation for *C. bilineata*. Morphology and ITS-1 sequences depict a high degree of divergence that is consistent with species-level differences." (Authors)] Address: Pilgrim, E. M., Dept Biol., Utah St. Univ., Logan, UT 84322, USA

3623. Richardson, J.M.L. (2002): Burst swim speed in tadpoles inhabiting ponds with different top predators. *Evolutionary Ecology Research* 4(5): 627-642. (in English). ["Selection is likely to favour anti-predator strategies that are effective against predators encountered frequently. Larval anuran communities fall along a gradient of pond permanency and pond permanency also affects the type of top predator (including Odonata) present. These environmental factors combine to create distinct categories of pond types. In this study, I quantified the predator avoidance trait burst swim speed and related traits for 14 anuran species found in three pond types and within three taxonomic families. Absolute swim speed differed significantly among species and among taxonomic families. Inclusion of size in the model revealed a three-way interaction between size, habitat and taxonomic family. Tail beat frequency and body

shape differed significantly among species, but with no pattern by family or habitat. Functional relationships among traits also did not differ among family by habitat groups. The evolution of swim speed was significantly correlated with the evolution of increased size. In general, these results suggest that anurans have invaded new pond types using multiple mechanisms to cope with the predators that are present." (in German, with English summary). [Nordrhein-Westfalen, Germany; in the framework of saprobial examinations of 75 sample sites along running waters, *Cordulegaster boltonii* was recorded at 7 sample sites, while *Thecagaster bidentata* was traced only one time. These records are mapped together with literature data and records from unpublished expertises and a Ms thesis. The localities are described in detail, and the regional distribution of the species is discussed.] Address: Riedel, H.-W., Stadt Bergisch Gladbach, Fachbereich Umwelt und Technik, Wilhelm-Wagner Platz, D-51429 Bergisch Gladbach, Germany

3629. Switzer, P.V. (2002): Territory quality, habitat selection, and competition in the Amberwing Dragonfly, *Perythemis tenera* (Say) (Odonata: Libellulidae): population patterns as a consequence of individual behavior. *J. Kans. ent. Soc.* 75(3): 145-157. (in English). ["Basic habitat selection theory predicts that individuals will prefer relatively high quality habitats over low quality habitats. This preference may affect settlement patterns, with higher quality habitats being occupied first and more frequently. If locations vary in quality and good locations are limited, individuals may compete for the best locations rather than settle in lower quality sites. Thus, any factors which influence the number of individuals in an area may potentially affect patterns of habitat occupation. In this study, I tested these ideas using the settlement and fighting patterns of a territorial dragonfly, *P. tenera*. Females consistently arrived later and departed earlier than males. Male and female arrival, and male departure, was correlated with temperature, with earlier arrivals and later departures on warm days. More males were present at the pond as the summer progressed and on warmer days, but the number of females was not related to date or temperature. The amount of fighting for territories increased as the number of males increased. Individuals tended to occupy high quality sites (i.e., sites with a higher number of matings per minute occupied) first within a day, and were more likely to occupy low quality sites when the number of males on the pond was relatively high. The locations that were occupied first during a day were of relatively higher quality and more likely to be occupied by site-faithful males (i.e., males returning to their previous day's location) than those occupied later in the day. Finally, higher quality sites were occupied more often, had more fighting on them, and had a higher proportion of escalated fights than lower quality sites. These results indicate that patterns of competition and habitat occupation are a result of relationships among local breeding population size, individual behavior (e.g., preference for sites and reaction to environmental conditions), and habitat availability and quality." 3632. Walia, G.K.; Sandhu, R. (2002): Comparative chromosome data on twenty three species of family Coenagrionidae (Zygoptera: Odonata). *Bionature* 22(2): 79-97. (in Chinese with English summary). ["Karyological investigations have been carried out on 23 species of seven genera belonging to family Coenagrionidae. These have been collected from states of North-west and North-East India during pre-monsoon and post-monsoon seasons. Among these; 21 are male species and 4 are female species. In males, 16 species reveal $2n=27$ as diploid chromosome number and $2n=25$ in remaining five species. In females, all the species possess $2n=28$ as diploid chromosome number. All the species have XO-XX type sex determining mechanism. Autosomal fragmentation has been observed in *Agriocnemis obscura* (female) [= *Agriocnemis rubescens* Selys, 1877], *Ceriagrion coromandelianum* (male), *Coenagrion dyeri* (female) [= *Cercion calamorum* (Ris 1916)], *Pseudoagrion decorum* (male) and *Pseudoagrion rubriceps* (male & female). Chromosome number varies from 27-60 in gonial metaphase plates. Sex element could not be differentiated in the fragmented stages. Behaviour and morphology of chromosomes during meiosis have been studied and compared within family and within genera." 3634. Woodward, G.; Hildrew, A.G. (2002): The impact of a sit-and-wait predator: Separating consumption and prey emigration. *Oikos* 99(3): 409-418. (in English). ["Reviews of the impact of invertebrate predators in enclosure/exclosure experiments suggest that much of the apparent depletion of prey is due to prey emigration induced by the predators. However, these generalisati-

ons derive mainly from studies of invertebrate predators that are predominantly active searchers (usually stoneflies) and of prey with strong avoidance responses (mainly mayflies). We examined the impact of a large sit-and-wait predator, the nymph of the dragonfly *Cordulegaster boltonii*, which has recently invaded Broadstone Stream as a new top predator. Field enclosure / enclosure experiments were conducted to assess the impact of the invader on the benthos. Depletion of prey varied seasonally and among taxa, and was highest when prey density and encounter rates were high. Mobile prey, although least likely to show a statistically significant response because of high exchange rates, were those most strongly depleted. Experimental channels were used to separate the relative contribution of consumption and emigration to total impact for the two most depleted prey species. Depletion of prey was due solely to consumption and predators did not induce emigration. We therefore urge caution in making generalisations about the impacts of invertebrate predators, since sit-and-wait and searching predators potentially have very different impacts." 3635. Worthen, W.B. (2002): The structure of larval odonate assemblages in the Enoree River basin of South Carolina. *Southeastern Naturalist* 1(3): 205-216. (in English). ["Odonate larvae were collected at 127 sites in the Enoree River and nine of its tributaries in the summers of 1999 and 2000. Mean odonate abundance, species richness, and Simpson's diversity were compared across tributaries and the main channel of the Enoree River with one-way ANOVA. These indices were significantly lower in Brushy Creek, Rocky Creek, and the Upper Enoree than in the other streams (Tukey multiple comparison test, $p < 0.05$). These three streams also differed from the others in species composition (MANOVA $p < 0.0001$), as measured by changes in the relative abundances of the five most abundant species: *Progomphus obscurus*, *Boyeria vinosa*, *Macromia illinoensis*, *Cordulegaster maculata*, and *Ophiogomphus mainensis*. For example, *O. mainensis* was nearly absent from Brushy, Rocky, and the Upper Enoree, but was a significant component of the assemblages in other streams. *Cordulegaster maculata* was rare in Rocky Creek but dominated the Upper Enoree where other species were less abundant. Brushy, Rocky, and the Upper Enoree are areas of either rapid residential development or known industrial contamination. The different structure of odonate assemblages in these streams may reflect the impact of these local anthropogenic effects." (Author)] Address: Worthen, W.B., Biology Department, Furman University, Greenville, SC, 29613, USA. E-Mail: worthen@furman.edu

3636. Zhang Y.-C.; Liu, B.; Zheng, Z.-m.; Li, L. (2002): DNA extraction and RAPD-PCR of insect specimens preserved with different methods. *Acta Entomologica Sinica* 45(5): 693-695. (in Chinese with English summary). ["Genomic DNA were extracted and amplified using the polymerase chain reaction and arbitrary primers from specimens of seven insect species: *Chrysomela vigintipunctata* (Scopoli) (Coleoptera: Chrysomelidae), *Harmonia axyridis* Pollard and *Coccinella septempunctata* Linnaeus (Col.: Coccinellidae), *Agrotis ypsilon* (Rottemberg) (Lepidoptera: Noctuidae), *Crocothemis servilia* Drury (Odonata: Libellulidae), and *Oxya abentata*

Willemse and *O. chinensis* (Thunberg) (Orthoptera: Caltantopidae). Of the specimens assayed, some had been naturally dried, some oven-dried and the remainder had been preserved in alcohol. The results suggest that, with respect to DNA extraction, oven-dried specimens and those preserved in alcohol are better than naturally dried specimens. Extraction of DNA using the CTAB method was easier, and more economical than other methods." 3637. Zimmermann, W. (2002): Checkliste der Libellen (Odonata) Thüringens. Stand 31.10.2002. *Checklisten Thüringer Insekten und Spinnentiere* 10: 5-11. (in German). [This is an update of Zimmermann's 1993-list, rising the number of Thuringian species by 9 to a total of 62 Odonata. More recent activities to study and map the odonate fauna of Thuringia, Germany are outlined. The species are listed and classified according to their regional abundance and the status (autochthonous, invasive, range extension). A few species are briefly commented.] Address: Zimmermann, W., Thomas-Müntzer-Str. 5, D-99423 Weimar, Germany

3638. Zimmermann, W. (2002): Zur Libellenfauna der Hochmoore und Sauer-Zwischenmoore des Thüringer Waldes. *Naturschutzreport* 19: 101-115. (in German). [The paper summarizes long lasting researches of the odonate fauna of 10 bogs and transition mires in Thüringen, Germany, starting in the 1960th. A total of 19 species was found, 14 are to consider as autochthonous. *Aeshna juncea*, *Somatochlora alpestris*, *S. arctica*, and *Leucorrhinia dubia* are considered on the regional level as characteristic odonate species for bogs and transition mires. These species are annotated in detail. Very intensive surveys of the Saukopfmoor result in an nearly constant species spectrum over 30 years. *L. dubia* is the eu-dominant species in the total of the surveyed habitats.] Address: Zimmermann, W., Thomas-Müntzer-Str. 5, D-99423 Weimar, Germany

3639. Zurek, R. (2002): Upper Vistula River: Response of aquatic communities to pollution and impoundment. VIII. Zooseston. *Polish Journal of Ecology* 50(2): 201-221. (in English). ["Zooseston of the Vistula River section almost 340 km long was investigated in the years 1997/98. In 99 samples collected 90 species of rotifers, 16 cladocerans, 9 copepods and other animals belonging to: Harpacticoidea, Oligochaeta, Nematoda, Chironomidae, Odonata, Simuliidae, Tardigrada and Coelenterata were found. Multiple regression analysis showed that the number of rotifers is significantly correlated with basic chemical indicators of water trophic state - phosphate, nitrate and nitrite as well as with the number of copepods which are usually predators. The numbers of copepods depends on the availability of possible prey, i.e. rotifers and cladocerans. Multiple regression confirmed known dependence of cladocerans from trophic conditions. Clustering of similarity matrices showed complex structure of sestonic assemblages on rhithral-potamal gradient additionally modified by hydrotechnical constructions. These constructions broke old river continuum. Ordination of sites gave complex pattern not only representing a simple gradient rhithral - potamal but also all transient stages caused by hydrotechnical construction (large dam reservoir) or by inflows of polluted waters from the tributaries. Ecologi-

cal meaning of principal component ordination for river zooseston assemblages is not simple and might be susceptible of various interpretations." 3641. Adams, M.J.; Pearl, C.A.; Bury, R.B. (2003): Indirect facilitation of an anuran invasion by non-native fishes. *Ecology Letters* 6(4): 343-351. (in English). ["Positive interactions among non-native species could greatly exacerbate the problem of invasions, but are poorly studied and our knowledge of their occurrence is mostly limited to plant-pollinator and dispersal interactions. We found that invasion of bullfrogs is facilitated by the presence of co-evolved non-native fish, which increase tadpole survival by reducing predatory macroinvertebrate densities. Native dragonfly nymphs in Oregon, USA caused zero survival of bullfrog tadpoles in a replicated field experiment unless a non-native sunfish was present to reduce dragonfly density. This pattern was also evident in pond surveys where the best predictors of bullfrog abundance were the presence of non-native fish and bathymetry. This is the first experimental evidence of facilitation between two non-native vertebrates and supports the invasional meltdown hypothesis. Such positive interactions among non-native species have the potential to disrupt ecosystems by amplifying invasions, and our study shows they can occur via indirect mechanisms." 3643. Altwegg, R. (2003): Hungry predators render predator-avoidance behavior in tadpoles ineffective. *Oikos* 100(2): 311-316. (in English). ["Behavioral responses of prey to their predators can critically alter community dynamics. Whether or not a prey responds, clearly depends on the effectiveness of that response.

The effectiveness on the other hand is predicted to depend on predator behavior. Actively searching predators can render the behavioral responses in their prey ineffective. Nevertheless, most studies investigating the optimal reaction of prey treated predators as immobile elements of the environment. I experimentally manipulated activity of poolfrog (*Rana lessonae*) tadpoles by keeping them at low and high food levels, and exposed them to three species of invertebrate predators (*Aeshna cyanea*, *Anax imperator*, and *Dytiscus marginalis*), whose activity also was manipulated through different food levels. Satiated, less active predators were more likely to kill hungry, more active tadpoles, but hungry predators killed hungry and satiated tadpoles about equally often. This result suggests that reducing their activity is a more effective strategy for tadpoles if the predators themselves are less active. On the other hand, against hungry, highly motivated predators, the behavioral avoidance strategies were essentially ineffective. Antipredator behavior is generally thought to stabilize the dynamics of predator-prey systems. The results presented here, however, suggest that the community dynamical consequences of antipredator behavior also critically depend on decisions made by predators." (Author)] Address: Altwegg, R., Dept of Biology, Univ. of Victoria, Victoria, BC, V8W 3N5, Canada. E-Mail: altwegg@uvic.ca

3644. Angelibert, S.; Giani, N. (2003): Dispersal characteristics of three odonate species in a patchy habitat. *Ecography* 26: 13-20. (in English). ["Dispersal has a potentially profound effect on the dynamics of populations especially when a population occupies a patchy habitat. Ponds surrounded by terrestrial landscape are an example of patchy distribution of physical conditions and constitute "islands" for odonates. Few studies have focussed on dispersal in odonates. We have used the direct method of dispersal observing (capture-mark-recapture technique) in order to estimate the degree of linkage in three patchy populations of odonate localised on three ponds. We also examined the differences in dispersal ability within and among three species (*Coenagrion puella*, *C. scitulum*, and *Libellula depressa*). The ponds were situated in southwest France on a limestone plateau. In this arid area, these ponds constitute the only surface water available and are relatively sparsely distributed. The size of the ponds ranged from 48 to 79 m² and they were 200 and 775 m apart. We demonstrated that three factors influence the dispersal ability of these odonates. The first is represented by the abiotic factors and especially weather conditions. This determines the number of days that dispersal is possible. The second is interspecific differences. We showed that sensitivity to weather conditions, species size and species behaviour influence dispersal ability. The third factor is the intraspecific characteristics. We demonstrated that there are differences in dispersal ability according to sex and age. To conclude, we discuss the importance of pond management to maintain the existing odonate populations and to facilitate introduction of new populations in this region where little exchange occurs between ponds." 3648. Bernard, M.F.; Fordyce, J.A. (2003): Are induced defenses costly? Consequences of predator-induced defenses in Western toads, *Bufo boreas*. *Ecology* 84(1): 68-78. (in English). ["Induced defenses are widespread in nature, and in amphibian larvae they are often expressed as altered behavior and changes in tail shape, color, and size. Theory predicts that induced defenses should be costly in the absence of a predator threat. No costs have been found for these defenses after metamorphosis. In this study, we tested for induced defenses in western toads, *Bufo boreas*, and measured larval and postmetamorphic consequences of these responses. Larvae were raised in either the presence or absence of nonlethal predator cues (including *Aeshna* sp.). Defense response of these larval treatments were measured during the larval stage and shortly after metamorphosis using both predator bioassays and quantification of the putative chemical defense common in toads, bufadienolides. We found no differences in larval morphology, growth rate, or development rate between the predator and control treatments. In the larval bioassays, some types of invertebrate predators consumed significantly fewer of the *B. boreas* larvae that were reared with predator cues compared to the control treatments. Bufadienolides were not present in *B. boreas* larvae. In the postmetamorphic bioassays, tiger salamanders (*Ambystoma tigrinum*) had longer handling times when consuming *B. boreas* that had developed in larval environments without predator cues compared to predator-treatment *B. boreas*. However, postmetamorphic *B. boreas* from predator cue larval environments had significantly higher concentrations of bufadienolides than did those from larval environments without predators, suggesting that these defenses are ineffective against tiger salamanders. Our results demonstrate

that there is plasticity in the chemical defenses of toads and suggest that induced larval defenses may incur costs that are only apparent after metamorphosis." 3655. Brackenbury, J. (2003): Escape manoeuvres in damselfly larvae: Kinematics and dynamics. *Jour. exp. Biol.* 206(2): 389-397. (in English). ["The kinematics and hydrodynamics of rapid escape manoeuvres executed by final-stage larvae of *Enallagma cyathigerum* were investigated using videography combined with a simple wake-visualisation technique. Two kinds of escape manoeuvres were identified: first, a 'rapid flex', comparable with the rapid C-start of fish, and, second, a 'rapid twist' that involves a helical contraction of the body inducing motion in the yaw, pitch and roll planes. In both cases, the initial flexion phase is concerned with re-orientating the body, the extensional phase with acceleration of the body in the new direction. The behaviour of the caudal fin during twist indicates considerable independence of movement and aspect control within the three constituent lobes. Dye deposited beneath the resting larvae showed a thrust jet shed into the wake at the end of the extension phase. The estimated momentum of the ring vortex containing the jet was similar to that imparted to the body at the start of the translational phase. Similarities between the swimming dynamics of damselfly larvae and fish are discussed, as well as the wider implications of these findings to other aquatic vertebrates whose normal, steady swimming appears to be based on unsteady manoeuvres." 3657. Braune, E. (2003): Live and get dry: A spatially explicit population model for Namibian Odonata. *Verhandlungen der Gesellschaft für Ökologie* 33: 297. (in English). [Verbatim: Within the scope of a BIOTA Southern Africa subproject a model for the dispersal of dragonflies in the arid regions of western Namibia was developed. The aim of this model is to predict changes in the diversity of Odonata under changing habitat conditions. These changes may be induced e.g. by intensive use of water resources or by climate change and may lead to a reduction of habitat quality and quantity. The modeling system consists of three parts: First, on the local level, habitat suitability models based on a one-year-monitoring program were calculated using logistic regression. Parameters used were biotic and abiotic parameters recorded during the monitoring, e.g. vegetation diversity, as well as parameters derived from remote sensing data based on LANDSAT 7 ETM+ satellite images like the density of open waters in the surrounding of the investigation sites or the NDVI. The second part of the model consists of a population dynamic mo-

del based on discrete difference-equations described by extended Leslie-matrices. The parameters of the model are formulated as dependent on food availability in the aquatic habitat. Interspecific competition in the larval stage of the dragonflies is also incorporated. This model depicts the typical life-cycle of tropical-centered dragonflies with a pattern of multivoltinism. Finally, the third part of the model combines the habitat suitability models and the population dynamics via a grid-based approach. In each grid cell the population dynamics is calculated in dependence of the respective habitat quality. Dispersal processes are modeled by a stochastic distribution of mature and immature adults in dependence of the relative population density and the suitability of the habitat. During the dispersal process there is a differentiation between long-distance and short-distance dispersal, so that even habitats in greater distances can be occupied provided that they exhibit a better habitat quality. By applying different scenarios of changing habitat quality, e.g. grazing cattle reducing the vegetation diversity, or habitat quantity, e.g. building of dams in the upper course of a river reducing, the available amount of water downstream, to the grid-based replication of the landscape, this model system offers the possibility to analyze the spatio-temporal development of Namibian Odonata and the consequences of changes in the environment. This grid-based formulation of a landscape can be used to apply different scenarios of changing habitat quality or quantity. So e.g. the destruction of habitats or of the vegetation diversity by grazing cattle can be simulated. Another possible scenario is the building of dams leading to a reduction of the available amount of water downstream. This model system offers the possibility to analyze the spatio-temporal development of Namibian Odonata and the consequences of changes in the environment.] Address: Braune, Eva, Institute of Geocology, Technical University of Braunschweig, Germany. 3660. Briers, R.A.; Biggs, J. (2003): Indicator taxa for the conservation of pond invertebrate diversity. *Aquatic Conservation* 13(4): 323-330. (in English). ["1. Ponds are a valuable re for the conservation of freshwater biodiversity, but are often extremely numerous in a given

area, making assessment of the conservation value of individual sites potentially time consuming. 2. The use of indicator taxa, the species richness of which is representative of total site species richness, may provide one way to improve the efficiency of survey work. However, such indicators are poorly developed for freshwater systems. 3. A data set was used describing the occurrence of macroinvertebrate taxa in ponds in Oxfordshire, UK, to assess the extent to which variation in the species richness of selected taxa most consistently represented variation in all other taxa. 4. Coenagriidae (Odonata) and Limnephilidae (Trichoptera) reflected the variation in species richness of other taxa most consistently, with Coenagriidae showing the best overall performance as an indicator taxon. 5. For both suggested indicator taxa, selection of sites based solely on the presence of at least one species of indicator would represent over 95% of all species recorded across all sites. 6. Further investigation in different geographical regions is necessary to establish whether these relationships are consistent over a wider area." (Authors)] Address: Briers, R.A. 3664. Buden, D.W.; Miller, J.Y. (2003): The butterflies of Pohnpei, eastern Caroline Islands, Micronesia. Pacific Science 57(1): 1-8. (in English). ["14 species of butterflies are recorded from Pohnpei, Micronesia, seven for the first time. None is endemic to the island; all are widely distributed in the western Pacific, including parts of Indo-Australia, with many extending into or beyond southeastern Asia. A long history of plant introductions and agricultural experimentation may have facilitated dispersal of butterflies to the island and provided a broad selection of host plants for those arriving otherwise unassisted. At least one, and possibly two or more, unidentified species apparently confined to deep forest habitats were seen but not collected during this study. Compared with the local odonate fauna, the butterflies of Pohnpei differ in reaching their greatest abundance and species diversity in the lowlands, in lacking endemic species, and probably in having a higher turnover rate." (Authors)] Address: Buden, D.W., Division of Natural Science and Mathematics, College of Micronesia-FSM, Kolonia, P.O. Box 159, Pohnpei, FM 96941, Micronesia. E-Mail: donbuden@comfsm.fm

3665. Burbach, K. (2003): Verbreitung und Habitate von *Leucorrhinia albifrons* in Bayern (Odonata: Libellulidae). Libellula Supplement 4: 105-132. (in German, with English summary). ["*L. albifrons* has been observed in at least 29-32 locations in 15 areas in Bavaria, Germany. Since 1995 the species has been recorded at only five locations. Three of these observations are from confirmed breeding sites; the other two are of a single male. At one of the breeding sites the species has probably been extirpated due to changes in habitat structure. The two remaining breeding sites have been known since 1993 and 1998, respectively. Characteristic habitat factors are low nutrient levels, the presence of vegetation immediately below the water surface and the (near) absence of fish. pH-value is apparently of little significance, since *L. albifrons* is known to occur in acidic as well as in calcareous bodies of water. The aquatic vegetation differs accordingly: whereas under calcareous conditions stoneworts (Characeae) and pondweeds (*Potamogeton* spp.) may be predominant, under acidic conditions floating sphagnum mats are common. Probable causes for the decline of the species are the eutrophication of breeding sites and the introduction of fish. The latter occurs even in smaller bodies of water, which are not suitable for stocking with fish. Especially the introduction of fish spp. which churn up the pond bottom or destroy vegetation (carp, grass carp) is likely to have contributed to the significant decline. Suggestions for the protection of the species are presented. The implementation of a monitoring programme for the last remaining populations is proposed." 3671. Combes, S.A.; Daniel, T.L. (2003): Flexural stiffness in insect wings. II. Spatial distribution and dynamic wing bending. *Jour. exp. Biology* 206(17): 2989-2997. (in English). ["The dynamic, three-dimensional shape of flapping insect wings may influence many aspects of flight performance. Insect wing deformations during flight are largely passive, and are controlled primarily by the architecture and material properties of the wing. Although many details of wing structure are well understood, the distribution of flexural stiffness in insect wings and its effects on wing bending are unknown. In this study, we developed a method of estimating spatial variation in flexural stiffness in both the spanwise and chordwise direction of insect wings. We measured dis-

placement along the wing in response to a point force, and modeled flexural stiffness variation as a simple mathematical function capable of approximating this measured displacement. We used this method to estimate flexural stiffness variation in the hawkmoth *Manduca sexta*, and *Aeshna multicolor*. In both species, flexural stiffness declines sharply from the wing base to the tip, and from the leading edge to the trailing edge; this variation can be approximated by an exponential decline. The wings of *M. sexta* also display dorsal/ventral asymmetry in flexural stiffness and significant differences between males and females. Finite element models based on *M. sexta* forewings demonstrate that the measured spatial variation in flexural stiffness preserves rigidity in proximal regions of the wing, while transferring bending to the edges, where aerodynamic force production is most sensitive to subtle changes in shape." 3673. Cordoba-Aguilar, A.; Salamanca-Ocana, J.C.; Lopezaraiza, M. (2003): Female reproductive decisions and parasite burden in a calopterygid damselfly (Insecta: Odonata). *Animal behaviour* 66: 81-87. (in English). ["There is currently a gap in sexual selection theory about how much the environment drives female mating decisions. We present field data that suggest that female sexual behaviour in the damselfly *Calopteryx haerorrhoidalis* is influenced by parasite burden. Male wing pigmentation in *Calopteryx* is a sexually selected trait that signals a male's ability to cope with eugregarine parasites (an intestinal parasite that feeds on the adult's ingested food). Because adult *C. haerorrhoidalis* females also show wing pigmentation, we examined whether this trait is similarly influenced by parasite burden and whether it may signal the female's reproductive value. Male *C. haerorrhoidalis* defend riverine substrates that females use for oviposition. After copulation and during oviposition, females are guarded by the copulating male against intruder males. Alternatively, females may avoid mating and 'steal' an oviposition site within a male's territory. In the present study, we found that the amount of female wing pigmentation was negatively correlated with the number of eugregarines present. Females with more parasites produced fewer eggs, survived fewer days, spent less time during courtship, 'inspected' fewer males before mating, had a lower mating success, were guarded for less time during oviposition and engaged in fewer 'stealing' events during oviposition. The reduced egg production and survival of

heavily infected females may result from eugregarine depletion of the females' consumed food reserves. Thus, to offset reduced longevity, heavily infected females may accept a mating more rapidly and mate with fewer males. 'Stealing' behaviour may be related to the female's differential use of sperm from some males, particularly high-quality males. Interestingly, males that mated with low-pigmented females showed greater variance in wing pigmentation than did males that mated with high-pigmented females. Possibly, female wing pigmentation may signal a female's reproductive value, which provides females with longer mate-guarding episodes and reduced interference from intruder males. This study points out one possible constraint, intestine parasites, that females may face during mating decisions. Because females in bad condition mate with males in both good and bad condition, this constraint may be pervasive enough to weaken the intensity of selection for a male sexually selected trait, wing pigmentation, and help to maintain its variation in phenotypic expression." (Authors)] Address: Cordoba-Aguilar, A., Centro de Investigaciones Biologicas, Universidad Autonoma del Estado de Hidalgo, Apdo. P. 69-1, Plaza Juarez, Pachuca, Hidalgo 42001, Mexico E-mail: acordoba@uaeh.reduaeh.mx

3674. Córdoba-Aguilar, A. (2003): A description of male and female genitalia and a reconstruction of copulatory and fertilisation events in *Calopteryx haemorrhoidalis* (Vander Linden) (Odonata: Calopterygidae). *Odonatologica* 32(3): 205-214. (in English). ["The genitalia have a "design" remarkably similar to those of other representatives of the family. The main female structures are the bursa copulatrix, a T-shaped spermatheca, a pair of vaginal plates bearing a variable number of mechanoreceptive sensilla, and a ganglion located at the VIII abdominal segment. The 6 intromittent organ is a curved, sclerotised aedeagus that ends in a distal penis head. This latter structure bears 2 lateral appendages which are covered by recurved spines. A construction of the fertilisation and copulatory events is proposed based on descriptive and experimental evidence in other zygopterans as well as in this species. The female genital anatomy suggests fertilisation occurs in the manner proposed for other odonates. Experimental evidence shown in this work suggests that, during fertilisation, the egg stimulates the mechanoreceptive sensilla and elicits contractile activity of the muscles that surround the sperm storage organs (SSOs). The contractile activity is likely to be mediated by the VIII abdominal segment ganglion. As a consequence of the muscular contractions, the SSOs eject sperm which arrive to the site where the egg is and fertilise it. During copulation, the aedeagus "imitates" the presence of an egg in the vaginal plates and stimulates the mechanoreceptive sensilla inducing spermathecal sperm ejection. It is likely that spermathecal sperm is ejected to the bursa copulatrix where it is removed by the penis head and lateral appendages. After this sperm displacement process, the copulating male's sperm, stored in the seminal vesicle, is transferred, through a canal-like passage, by the aedeagus to the SSOs. Since females exhibit a considerable intra- and inter-individual variation in sensillum distribution and number on the plates, it is discussed whether this may have an adaptive significance in terms of retaining more control over stored sperm for females during male stimulation." (Author)] Address: Cordoba-Aguilar, A., Centro de Investigaciones Biologicas, Universidad Autonoma del Estado de Hidalgo, Ap-

do. P. 69-1, Plaza Juarez, Pachuca, Hidalgo 42001, Mexico E-mail: acordoba@uaeh.reduaeh.mx

3675. Córroba-Aguilar, A. (2003): A note on territorial and mating behaviour in the dragonfly *Pseudoleon superbus* (Hag.) (Anisoptera: Libellulidae). *Notul. odonatol.* 6(1): 10. (in English). ["[...] Here I provide a short report on this species' sexual behaviour which was observed in Plan del Rio, Veracruz on June 9, 2002, from 13:00 to 15:00 h. Individuals of both sexes were seen in the river that surrounds this locality. Five males were seen patrolling each of five different ponds of varying diameter (3-20 m) and shallowness (0.30-3.0 m) which were fed by the river. [...] males were overtly aggressive against conspecific whenever these appeared on the pond, they were chased over distances as long as 30 m. Males also showed fidelity for concrete sites on the ponds. Given these activities, this species seems to exhibit territorial behaviour. During observations, two females were seen arriving to two ponds at different times (13:30 and 13:56 h resp.). They were taken with no apparent pre-copulatory courtship by the territorial male. Copulation was in the air and took 5 and 7 seconds for each pair. Soon after this, females went directly to sites with submerged vegetation and started an in-flight oviposition. [...] mating males showed non-contact guarding during oviposition. During this, copulating males chased approaching males (number of males chased for each male: 3 and 5, resp.). In one occasion, a male chased a conspecific male and while this pair was some metres away from the pond, another male took the ovipositing female in copulation which lasted 5 seconds. The female continued oviposition even when the previous copulating male came back after 58 seconds, but no copulation ensued." 3676. Couteyen, S.; Papazian, M. (2003): Contribution a la connaissance des Odonates de l'île de la Reunion 6. Description de la larve de *Coenagriocnemis reunienensis* (Fraser, 1957) (Odonata, Coenagrionidae). *Entomologiste* 59(1-2): 9-12. (in French with English summary). [The larva of the endemic *C. reunienensis* is described. Some information on the biology of the species is included.] Address: Couteyen, S., 188 Chemin Nid Joli, F-97430, Le Tampon, La Reunion, France

3677. Mauersberger, R., (2003): *Crocothemis erythraea* recorded in northeastern Germany (Odonata: Libellulidae). *Libellula* 22(1/2): 55-60. (in German, with English summary). [Three males of *C. erythraea* were observed on July 29, 2002, and one male on June 17, 2003 at glacial formed lakes near Rheinsberg (53,1°N) resp. near Neustrelitz (53,4°N), Brandenburg, Germany. The specimen activity pattern were focused on shallow bays with dense structures consisting of *Ceratophyllum*, *Myriophyllum*, *Utricularia*, and *Nymphaea*, together with other dragonfly species e.g. *Leucorrhinia caudalis*. It is to be considered as the northernmost records in Germany.] Address: Mauersberger, R., Bahnhofstr. 24, D-17268 Templin, Germany. E-Mail: foerdervereinUckermaerk.Seen@t-online.de

3678. Crumrine, P.W.; Crowley, P.H. (2003): Partitioning composition of risk reduction in a dragonfly-fish intraguild predation system. *Ecology* 84(6): 1588-1597.

(in English). ["Risk to prey imposed by intraguild predation (IGP) can be influenced by a number of factors, yet to date, few studies have measured the contributions of these factors to overall risk. A three-species IGP system with larvae of the dragonfly *Anax junias* as IG (top) predators, larvae of the dragonfly *Plathemis lydia* as IG prey (intermediate predators), and fathead minnow hatchlings (*Pimephales promelas*) as shared prey was used to estimate the contribution of the following three factors to shared-prey mortality rate in combined predator treatments: (1) the trophic effect of the IG predator on IG prey density; (2) the effect of reduced shared prey consumption by the IG prey in the presence of the IG predator; and (3) the effect of alternative prey for the IG predator. These factors were integrated into a model of multiple predator effects. To quantify minnow mortality, *P. promelas* were exposed to *A. junius* only, *P. lydia* only, *A. junius* and *P. lydia*, or neither in a two-by-two factorial design. Additional treatments, in which one or both predators were unable to feed, were used to isolate behavioral (activity level) changes in dragonfly larvae. When predators preyed in combination on *P. promelas* their impact was less than that of the summed effects of the two predators, each in the absence of the other a result termed risk reduction. *A. junius* consumed a significant number of *P. lydia* when they were present (i.e., IGP), and behavioral interactions between *A. junius* and *P. lydia* were asymmetric. The presence of *A. junius* caused *P. lydia* to become less active, while the presence of *P. lydia* elicited a diet shift in *A. junius* to include some *P. lydia*. Interactions between predator species, specifically IGP, influenced prey survival. Trophic and behavioral effects of IGP were similar in magnitude. These results highlight the importance of trophic and behavioral interactions in predator-prey systems and also suggest that effects of multiple predators may not be predictable based on the sum of individual effects. Determining the effects of multiple predators requires the identification of mechanisms that contribute to nonadditive prey responses." 3681. Daigle, J.; Mauffray, B.; Beaton, G. (2003): 2003 SE meeting at Lafayette, Georgia. *Argia* 15(2): 9-10. (in English). [The regional meeting held in late May 2003 intended to contribute to the knowledge of the odonate fauna of three counties (Chattooga, Dade, Walker County) in the extrem northwest of Georgia, USA. Two new state records (*Arigomphus villosipes*, *Lestes eurinus*) and several second state records succeeded. Some emphasis ist given to *Gomphus lineatifrons*.] Address: Daigle, J., 2166 Kimberley Lane, Tallahassee, FL 32311, USA. E-mail: jdaigle@nettally.com

3682. de Araujo-Coutinho, C.J.P.; Viviani Cunha, A.; Serra-Freire, N.M.; de Mello, R.P. (2003): Evaluation of the impact of *Bacillus thuringiensis* serovar israelensis and temephos, used for the control of *Simulium* (*Chirostilbia*) *pertinax* Kollar, 1832 (Diptera, Simuliidae) on the associated entomofauna, Paraty, state of Rio de Janeiro, Brazil. *Memorias do Instituto Oswaldo Cruz* 98(5): 697-702. (in English). ["The study was set up to evaluate the impact of two commercial larvicide formulations, *Bacillus thuringiensis* serovar israelensis base (Bti) at 15 ppm/l min and temephos at 0.03 ppm of active ingredient, used to control *Simulium pertinax* populations, on associated non-target entomofauna occupying the same breeding sites. The experiments were carried out on the Pedra Branca and Muricana rivers, on the slopes of Serra do Mar massif, municipality of Paraty, state of Rio de Janeiro, Brazil. B. t. i. was applied to the river Pedra Branca and temephos to the river Muricana. On both rivers, treatment and control sections were labeled as such, each one with two observation posts: slow moving water and fast water regions respectively. Artificial substrata was used to evaluate the abundance of associated entomofauna. Attached immature stages of arthropods were removed from both of its surfaces fortnightly. Were collected, from the two rivers, 28 477 specimens of the entomofauna associated with *S. pertinax*. The families Hydropsychidae, Chironomidae, Bactidae, Simuliidae, Blephariceridae and Megapodagrionidae were represented. These was an impact of temephos on the entomofauna associated with *S. pertinax* only in Simuliidae and Chironomidae, and to B. t. i. only in Simuliidae. However, the reduction in their numbers was not statistically significant." 3686. Devin, S.; Piscart, C.; Beisel, J.N.; Moreteau, J.C. (2003): Ecological traits of the amphipod invader *Dikerogammarus villosus* on a mesohabitat scale. *Archiv für Hydrobiologie* 158(1): 43-56. (in English). ["Since 1995, *Dikerogammarus villosus* SOWINSKI, a Ponto-Caspian amphipod species, has been invading most of Western Europe's hydrosystems. *D. villosus* geographic extension and quickly increasing population density has enabled it to become a major component of macrobenthic assemblages in recipient ecosystems. The ecological characteristics of *D. villosus* on a mesohabitat scale were investigated at a station in the Moselle River. This amphipod is able to colonize a wide range of substratum types, thus posing a threat to all freshwater ecosystems. Rivers whose dominant substratum is cobbles and which have tree roots along the banks could harbour particularly high densities of *D. villosus*. A relationship exists between substratum particle size and the length of the individuals, and spatial segregation according to length was shown. This allows the species to limit intra-specific competition between generations while facilitating reproduction. A strong association exists between *D. villosus* and other Ponto-Caspian species, such as *Dreissena polymorpha* and *Corophium curvispinum*, in keeping with Invasional Meltdown Theory. Four taxa (*Coenagrionidae*, *Calopteryx splendens*, *Corophium curvispinum* and *Gammarus pulex*) exhibited spatial niches that overlap significantly that of *D. villosus*. According to the predatory behaviour of the newcomer, their populations may be severely impacted." 3687. Dijkstra, K.-D. (2003): Dragonflies and damselflies (Odonata) in Bwindi Impenetrable and Semliki National Parks, Uganda. Final report for the project: "Biogeography and ecology of dragonflies (Odonata) of South and West Ugandan forests", 1 September 2003. In collaboration with: Viola Clausnitzer, Philipps-University of Marburg, Marburg, Germany and John Joseph Kisakye & Derek Pomeroy, Makerere University Institute for Environment and Natural Resources, Kampala, Uganda: 8 pp. (in English). [65 species from Bwindi Impenetrable, and 91 species from Semliki National Parks are listed in tables and briefly commented according to their (biogeographical) range, ecology, sampling locality. The species composition of both

parks is compared, and some remarkable species including some new to science are briefly discussed.] Address: Dijkstra, K.-D., Gortestraat 11, 2311 MS Leiden, The Netherlands, kddijkstra@hetnet.nl

3688. Dijkstra, K.D.; Lempert, J. (2003): Odonate assemblages of running waters in the Upper Guinean forest. *Archiv für Hydrobiologie* 157(3): 397-412. (in English). ["In order to describe the assemblages of adult Odonata of running waters in the Upper Guinean forest, 36 sites in Liberia and Ghana were analysed using Non-metric Multidimensional Scaling. Five groups were identified, which correspond with different assemblages in the sequence of habitats from small streams to large rivers. Taxonomically related species demonstrate distinct ecological segregation within this gradient, occupying different sections of running waters, or different microhabitats therein. The balance of sun and shade, resulting from a varying degree of habitat openness, is thought to be an important factor in habitat selection, but it is difficult to distinguish from other factors associated with stream size. Anthropogenic opening of stream habitat (e.g. by deforestation or damming) can downscale the present fauna, i.e. result in the invasion of species of downstream habitats (more open) and the disappearance of upstream (dense forest) species." (Authors)] Address: Lempert, J., Vereinsstr. 41, D-20357 Hamburg, Germany. E-mail: jochen.lempert@gmx.de

3689. Dijkstra, K.-D. (2003): Problems in Chlorocypha classification: four cases from West Africa and a discussion of the taxonomic pitfalls (Odonata: Chlorocyphidae). *International Journal of Odonatology* 6(2): 109-126. (in English). ["The taxonomy of Chlorocypha species is problematic due to variability and the paucity of morphological characters. Subspecies *radix* of *C. glauca* is raised to specific rank. *C. sharpae* is found to be a synonym of *C. luminosa*. The synonymy of *C. jejuna* with *C. luminosa* is rejected. The former species is similar to the Southern African *C. consueta* and differences are stated. *C. dispar ovulosa*, *Libellago dispar fraseri* and *C. mutans* are synonyms of *C. pyriformosa*, although the lost type series of *fraseri* appears to have contained immature specimens of *C. dispar*. Trends in African chlorocyphid variation, subsequent taxonomic pitfalls and suggested guidelines to deal with them are discussed. The main problems are age and environment related melanization intensity, dark patterns caused by reversible temperature-induced colour change, especially in teneral, and the switch between reddish and bluish colours in species with bicoloured abdomens." (in English). ["The food habits and prey base of the endangered Southwestern Willow Flycatcher (*Empidonax traillii* extimus) are not well known. We analyzed prey remains in 59 fecal samples from an intensively-studied population of this flycatcher at the Kern River Preserve in southern California. These samples were collected during the nesting season in 1996 and 1997 from adults caught in mist nets, and from nestlings temporarily removed from the nest for banding. A total of 379 prey individuals were identified in the samples. Dominant prey taxa, both in total numbers and in percent occurrence, were true bugs (Hemiptera), flies (Diptera), and beetles (Coleoptera). Leafhoppers (Homoptera: Cicadellidae), spiders (Araneae), bees and wasps (Hymenoptera), and dragonflies and damselflies (Odonata) were also common items. Diet composition was significantly different between years, due to a large difference in the numbers of spiders between 1996 and 1997. There was also a significant difference between the diet of young and adults, with the diet of young birds having significantly higher numbers of odonates and beetles. There was a trend toward diet differences between males and females, but this was not significant at the $P = 0.05$ level." (Authors)] Address: Drost, C.A., U.S. Geological Survey, Southwest Biological Science Center, Colorado Plateau Field Station, 2255 North Gemini Drive, Flagstaff, AZ, 86001, USA

- 3694.** Dumont, H.J. (2003): Odonata from the Republic of Mongolia and from the Autonomous Region of Inner Mongolia. *International Journal of Odonatology* 6 (2): 127-146. (in English). ["Thirty-five dragonfly species are reported from Mongolia and Inner Mongolia. Three are first records (*Coenagrion johanssoni*, *Erythromma najas humerale* Selys 1887, *Sympetrum speciosum haematoneura* Fraser). A non-parametric test is used to determine the total number of species to be expected. It suggests that the current number of 62 may be asymptotically complete, except for some specific zones like the Bulgan valley in the south-west, and the upper catchment of the Amur River, which have a distinctive fauna. From a biogeographic point of view, the Mongolian fauna is predominantly of impoverished Eurosibirian extraction. The south of Mongolia (the Gobi) and adjacent Inner Mongolia are, however, enriched with a significant fraction of East-Mediterranean and Irano-Turanian species, taking advantage of the Dzungarian corridor(s). This is particularly true of the fauna found in the small cis-Altai 'exclave' of the extreme south-west of
- the country. True Oriental species are rare, but East Palaearctic species (e.g. of the genus *Cercion*) are well-represented, especially south and east of the Gobi desert, which itself remains in need of further exploration." (Author) *Coenagrion lunulatum*, *Cercion v-nigrum*, *Orthetrum brunneum lineostigma*, *Sympetrum speciosum haematoneura*, and *S. hypomelas* are figured, and discussed in detail.] Address: Dumont, H.J., Univ. - 3696.** Dyrzcz, A.; Flinks, H. (2003): Nestling food of the congeneric and sympatric Rusty-margined and Social flycatchers. *Journal of Field Ornithology* 74(2): 157-165. (in English). ["We studied the food of nestling Rusty-margined (*Myzotetes cayanensis*) and Social flycatchers (*M. similis*) in 1998 and 1999 at Barro Colorado Island, Panama. Food samples were taken from nestlings by fecal analysis and the neck-collar method. In both species most food items were beetles, winged ants, dragonflies, spiders, and seeds of *Miconia* spp. Water animals (mainly backswimmers, freshwater snails, and dragonfly larvae) constituted 7.8%-13.5% of animal prey. The nestlings of the Social Flycatcher received significantly more flying insects, while the proportion of fruits and seeds was significantly higher in the diet of Rusty-margined Flycatcher nestlings. Length of animal prey varied from 4-25 mm in the Rusty-margined Flycatcher and 2-50 mm in the Social Flycatcher, and the length of fruits and seeds were 4-11 mm and 2-19 mm, respectively. The average length of animal food was larger in the Rusty-margined Flycatcher despite its slightly smaller size. The number of broods with nestlings or fledglings present in the study area was positively correlated with the abundance of fruits in the Social Flycatcher." (Authors)] Address: Dyrzcz, A., Department of Avian Ecology, Wrocław University, Sienkiewicza 21, 50-335, Wrocław, Poland. E-Mail: dyrzcz@biol.uni.wroc.pl
- 3697.** Ellenrieder, N. von; Garrison, R.W. (2003): A synopsis of the genus *Triacanthagyna* (Odonata: Aeshnidae). *International Journal of Odonatology* 6(2): 147-184. (in English) ["This synopsis of adult *Triacanthagyna* includes the revalidation of two species thought to be synonyms (*T. nympha* and *T. obscuripennis*), the description of a new species (*T. williamsoni*; type locality: Peru, Tingo Maria), keys to both sexes, illustrations of diagnostic characters, and distribution maps of all species. A phylogenetic assessment of the nine species is included, using outgroup comparison and parsimony algorithm. The cladistic analysis shows *Triacanthagyna* to be partitioned into two monophyletic groups: (1) two species lacking humeral, interpleural and metapleural dark stripes on pterothorax and with male cerci narrowing gradually at tip (*T. septima* and *T. obscuripennis*), and (2) six species with male cerci bearing subbasal teeth (*T. satyrus*, *T. caribbea*, *T. ditzleri*, *T. williamsoni*, *T. nympha* and *T. trifida*)." - 3698.** Ellenrieder, N. von (2003): A synopsis of the Neotropical species of 'Aeshna' fabricius: The genus *Rhionaeschna* Förster (Odonata: Aeshnidae). *Tijdschrift voor Entomologie* 146(1): 67-207. (in English). [This study includes a revisionary, phylogenetic and biogeographical analysis of Neotropical components of *Aeshna* Fabricius characterized by a midventral tubercle on abdominal sternum I. Phylogenetic relationships of the Neotropical species of *Aeshna* were inferred based on 39 adult characters. Ingroup taxa included 68 out of the 85 species currently assigned to *Aeshna*, and two species each of *Andaeshna* De Marmels and *Anaciaeschna* Selys. *Oreaeschna dictatrix* Lieftinck was chosen as outgroup. The strict consensus tree obtained after successive weighting revealed that *Aeshna* is not monophyletic; some of its species are more closely related to *Anaciaeschna* or *Andaeshna*. The name *Aeshna* should consequently be restricted to the Holarctic group including the type species *Aeshna grandis* Fabricius. In the present synopsis the generic name *Rhionaeschna* Förster is assigned to the New World group characterized by the presence of a conical tubercle on abdominal sternum I, comprising 39 species formerly assigned to *Aeshna*. The synopsis includes keys to adults of both sexes, diagnoses, biological notes, distribution maps and more than 400 diagnostic illustrations. *Rhionaeschna demarmelsi* sp. n. is described, *R. maita* Förster is considered a junior synonym of *R. brevifrons* (Hagen), *R. planaltica* (Ris) is considered a valid species, not a synonym of *R. variegata* (Fabricius), *R. planaltica* (Calvert) is raised to specific rank, 'Aeshna' *williamsoniana* Calvert, formerly included in the subgenus *Hesperaeschna* Cockerell, is excluded from *Rhionaeschna*, and lectotypes are designated for *R. maita*, *R. intricata* (Martin), *R. multicolor* (Hagen), *R. bonariensis* (Rambur), *R. diffinis* (Rambur), and *R. perralta*. Females of three species and larvae of 16 species are still unknown. *Rhionaeschna* occurs from southern Argentina to southern Canada, but is primarily Neotropical with its highest diversity along the Andean mountain range between Venezuela and Bolivia. It is absent from the Amazon basin, only three species occur north to the Neotropical region. The sister group of *Rhionaeschna* includes some African species of 'Aeshna' (*A. rileyi* Calvert, *A. subpupillata* McLachlan and *A. moori* Pinhey). *Rhionaeschna* plus the African clade constitute the sister group of *Andaeshna*, *Anaciaeschna*, *Anax* Leach, *Hemianax* Selys and several species of 'Aeshna' of uncertain affinities (i.e. *A. affinis* Vander Linden, *A. brevistyla* Rambur, *A. ellioti* Kirby, *A. mixta* Latreille, *A. isoceles* Muller and *A. williamsoniana*); the phylogenetic relationships within this complex are not yet known and their resolution is beyond the scope of this study. *Rhionaeschna* is absent from the Brazilian shield. Its related species and genera ('*A. rileyi*', '*A. subpupillata*', '*A. moori*' in Africa; '*A. brevistyla*' in Australia and New Zealand, *Andaeshna* in the Andes and '*A. williamsoniana*' in Central America, '*A. isoceles*' and highest species numbers of *Anaciaeschna*, *Hemianax* and *Anax* species in the Indo-Australian region) display a low diversity in Africa, which suggests a trans-Pacific rather than trans-Atlantic (Gondwanian) track, as has been hypothesized for other groups of similarly distributed odonates." - 3702.** Freeland, J.R.; May, M.; Lodge, R.; Conrad, K.F. (2003): Genetic diversity and widespread haplotypes in a migratory dragonfly, the common green darner *Anax junius*. *Ecological Entomology* 28(4): 413-421. (in English). [1. Species that undertake regular two-way migration may be expected, through population connectivity, to exhibit some level of genetic similarity over broad spatial scales. Although seldom following two-way migration, highly mobile insect species tend to exhibit either low haplotype diversity and no phylogeographic structuring, or relatively high haplotype diversity and pronounced phylogeographic structuring. 2. This study reveals the first wide-scale genetic characterization of a migratory dragonfly, *A. junius*. Unusually for insects, north-south two-way migration is common in this species, although not obligatory. In at least part of its

range, some individuals follow an extended developmental period and overwinter in a state of diapause. 3. Mitochondrial sequence data were obtained from 92 *A. junius* individuals collected from 35 sites across Canada, U.S.A., and Mexico. These revealed 38 haplotypes, some of which were extremely widespread, although the majority (27 haplotypes) was found in only one individual. In contrast to previous studies on mobile insects, the overall pattern was of relatively high haplotype diversity in the absence of phylogeographic structuring. 4. Migrants and non-migrants, which sometimes shared haplotypes, were distributed across multiple genetic lineages. This suggests that, contrary to some earlier assertions, developmental pathways in this species may be plastic. Such plasticity would allow highly mobile species to adapt to a range of environmental conditions, and may be key to the widespread distribution of multiple haplotypes." 3707. Guerbaa, K. (Ed.) (2003): Atlas des libellules du Limousin. *Epops*, Hors Série 1: 110 pp. (in French). [In the beginning of the 20th century, René Martin surveyed the odonate fauna of the Limousin region in France. With focus on these data, the results of a mapping project referring to the period of 1980 to 2001 are presented and discussed. More than 15000 species/location data sets are used to provide distribution maps. These are briefly commented. The style of the small book is very sophisticated: Black and white drawings - in most cases realised by Catie Faurie - and some black and white photographs build a very harmonic unit with the brief but competent textes. The book can be obtained by the Société Limousine d'Odonatologie et la SEPOL, 11, Rue Jauvion, F-87000 Limoges, France. Please add 10,- Euro to your order.] Address: Guerbaa, K., 1, rue de la Madonnette, F-87250 Bessines-sur-Gartempe, France

3708. Haas, F.; Waloszek, D.; Hartenberger, R. (2003): *Devonohexapodus bocksbergensis*, a new marine hexapod from the Lower Devonian Hunsrück Slates, and the origin of Atelocerata and Hexapoda. *Organisms Diversity & Evolution* 3(1): 39-54. (in English). ["We describe a new arthropod (approximately 75 mm long) from the Lower Devonian (Lower Emsian) Hunsrück Slates near Bundenbach, western Germany. The specimen is from an isolated piece of rock found on the quarry dump, precluding precise resolution of stratigraphic age. The Hunsrück Slates are marine sediments with a rich fauna of exclusively marine taxa, suggesting that our fossil was also marine. The animal has a small head with large compound eyes and long, filiform, myocerate antennae. Its trunk is divided distinctly into a thorax with three segments and three pairs of slender legs, and a post-thoracic domain composed of 35-40 limb-bearing segments of which the anteriormost are paired, stout, and ventrally-oriented leglets; the 3 ultimate limb-bearing segments bear longer, posteriorly-oriented and apparently specialised appendages. The overall appearance of the new form is reminiscent of Archaeognatha or Odonata. It is interpreted as a representative of the Hexapoda because of the possession of a three-segmented thorax and three pairs of legs that are clearly distinct from the posterior set. The large number of leg-bearing post-thoracic segments discriminates it from the Insecta, which possess 11 "abdominal" segments maximally, originally also leg-bearing. The formal systematic classification of the organism is: (Hexapoda (*Devonohexapodus bocksbergensis*+Insecta ("entognaths"+Ectognatha))). The morphology of the fossil and its environment suggest that the hexapody of hexapods did not evolve as an adaptation to terrestrial locomotion, but was already developed in the marine habitat. No terrestrial arthropods have changed their original tagmosis for biomechanical reasons, for example, no "myriapods" have reduced their leg numbers or modified their trunk to evolve a thorax and ab-

domen similar to insects. Walking exclusively on uniramous prosomal legs in the Chelicerata also occurred well before terrestrialization of this other euarthropodan group. It is not unlikely that the last common ancestor of the Hexapoda was large and that the small size of extant "entognaths" evolved due to reduction in their stem lineage. Being marine, the new fossil also has considerable impact on hypotheses about the early evolution of Atelocerata ("myriapods"+Hexapoda). For example, if their last common ancestor was aquatic, terrestrialization took place at least twice and tracheal breathing probably evolved independently in both taxa after terrestrialization." 3709. Haden, G.A.; Shannon, J.P.; Wilson, K.P.; Blinn, D.W. (2003): Benthic community structure of the Green and Colorado rivers through Canyonlands National Park, Utah, USA. *Southwestern Naturalist* 48(1): 23-35. (in English). ["We sampled the aquatic benthos at 6 remote sites on the Colorado and Green rivers through Canyonlands National Park, Utah, USA. This study provides the first published description of benthic standing mass, invertebrate community composition, and primary carbon for this portion of the Colorado River system. High suspended sediment concentrations prohibited growth of primary producers. The primary carbon for benthic invertebrates was terrestrial organic matter. The invertebrate community was composed of 49 taxa, mostly mayflies, caddisflies, and diptera, which were dominated by filterer/collector species. A smaller portion of the community was made up of predatory stoneflies and odonates. Standing mass of invertebrates on cobble substrates within a given site was stable over the multiyear sample period (1993 through 1996) and was comparable with other southwestern streams (overall mean = 0.41 g/m² ash-free dry mass +/- 0.01 SE). Invertebrate standing mass at each site was controlled by the availability of primary carbon. Primary carbon availability was controlled by supply to the site and retention within the site. Both aspects might be influenced by anthropogenic alteration of the river basin and discharge patterns upstream of the study site." ["At agricultural irrigation tanks, exuviae of *Selysiothermis nigra* were fixed to the substrate by their legs only, whereas *Crocothemis erythraea* and *Orthetrum cancellatum* additionally have contact with their abdomen two. The latter differ in the symmetry of the leg positions." (Author)] Address: von Hagen, H., Akazienweg 28, D- 58452 Witten, Germany. E-Mail: H.vonHagen@web.de

3711. Haines, T.A.; May, T.W.; Finlayson, R.T.; Mierzykowski, S.E. (2003): Factors affecting food chain transfer of mercury in the vicinity of the Nyanza site, Sudbury River, Massachusetts. *Environmental Monitoring & Assessment* 86(3): 211-232. (in English). ["The influence of the Nyanza Chemical Waste Dump Superfund Site on the Sudbury River, Massachusetts, was assessed by analysis of sediment, fish prey organisms,

and predator fish from four locations in the river system. Whitehall Reservoir is an impoundment upstream of the site, and Reservoir 2 is an impoundment downstream of the site. Cedar Street is a flowing reach upstream of the site, and Sherman Bridge is a flowing reach downstream of the site. Collections of material for analysis were made three times, in May, July, and October. Sediment was analyzed for acid-volatile sulfide (AVS), simultaneously-extracted (SEM) metals (As, Cd, Cr, Hg, Pb, Sb, Zn), and total recoverable Hg. The dominant predatory fish species collected at all sites, largemouth bass (*Micropterus salmoides*), was analyzed for the same suite of metals as sediment. Analysis of stomach contents of bass identified small fish (yellow perch *Perca flavescens*, bluegill *Lepomis macrochirus*, and pumpkinseed *Lepomis gibbosus*), crayfish, and dragonfly larvae as the dominant prey organisms. Samples of the prey were collected from the same locations and at the same times as predator fish, and were analyzed for total and methyl mercury. Results of AVS and SEM analyses indicated that sediments were not toxic to aquatic invertebrates at any site. The SEM concentrations of As, Cd, and Cr were significantly higher at Reservoir 2 than at the reference sites, and SEM As and Cd were significantly higher at Sherman Bridge than at Cedar St. Sediment total Hg was elevated only at Reservoir 2. Hg was higher at site-influenced locations in all fish species except brown bullhead (*Ameiurus nebulosus*). Cd was higher in bluegill, black crappie (*Pomoxis nigromaculatus*), and brown bullhead, and Cr was higher in largemouth bass fillet samples but not in whole-body samples. There were no seasonal differences in sediment or prey organism metals, but some metals in some fish species did vary over time in an inconsistent manner. Predator fish Hg concentration was significantly linearly related to weighted prey organism methyl Hg concentration. Largemouth bass Hg was significantly lower at Reservoir 2 in our study than in previous investigations in 1989 and 1990. High concentrations of inorganic Hg remain in river sediment as a result of operation of the Nyanza site, and fish Hg concentrations in river reaches downstream of the site are elevated compared to upstream reference sites. However, the differences are relatively small and Hg concentrations in largemouth bass from the site-influenced locations are no higher than those from some other, nearby uncontaminated sites. We hypothesize that this results from burial of contaminated sediment with cleaner material, which reduces bioavailability of contaminants and possibly reduces methylation of mercury." 3713. Hawking, J.H.; New, T.R. (2003): Interpreting dragonfly diversity to aid in conservation assessment: Lessons from the Odonata assemblage at Middle Creek, north-eastern Victoria, Australia. *Journal of Insect Conservation* 6(3) (2002): 171-178. (in English). ["In order to evaluate single-occasion sampling in compiling inventories for Odonata, larvae were sampled on 20 occasions from 1987-1990 at a site on Middle Creek, north-eastern Victoria, and adults sought also on each visit to more fully evaluate the diversity of the assemblage, and limitations of depending on a single life stage for this purpose. A total of 18 species (7 Zygoptera, 11 Anisoptera) included 15 species collected as larvae and 16 as adults. Few species were common as larvae, and about half the 2806 specimens identified were *Austrogomphus cornutus* Watson. *Orthetrum caledonicum* (Brauer) and *Ischnura heterosticta* (Burmeister) were also abundant, and these three species were also the most common as adults. The number of species obtained ranged from 2-9 on different occasions, and represent different 'habitat groups' within the local fauna. The Middle Creek odonate fauna appears to be much richer than that of a nearby site on the Kiewa River (12 species), and reasons for this are discussed. Seasonal variation in species representation and relative abundances are noted. Any single sample occasion provided insufficient knowledge of the total assemblage to interpret odonate diversity reliably." (Authors)] Address: New, T.R., Department of Zoology, La Trobe University, Bundoora, Vic., 3083, Australia

3714. Herbeck, J.T.; Novembre, J. (2003): Codon usage patterns in cytochrome oxidase I across multiple insect orders. *Journal of Molecular Evolution* 56(6): 691-701. (in English). ["Synonymous codon usage bias is determined by a combination of mutational biases, selection at the level of translation, and genetic drift. In a study of mtDNA in insects (including Odonata), we analyzed patterns of codon usage across a phylogeny of 88 insect species spanning 12 orders. We employed a likelihood-based method for estimating levels of codon bias and determining major codon preference that removes the possible effects of genome nucleotide composition bias. Three questions are addressed: (1) How variable are codon bias levels across the phylogeny? (2) How variable are major codon preferences? and (3) Are there phylogenetic constraints on codon bias or preference? There is high variation in the level of codon bias values among the 88 taxa, but few readily apparent phylogenetic patterns. Bias level shifts within the lepidopteran genus *Papilio* are most likely a result of population size effects. Shifts in major codon preference occur across the tree in all of the amino acids in which there was bias of some level. The vast majority of changes involves double-preference models, however, and shifts between single preferred codons within orders occur only 11 times. These shifts among codons in double-preference models are phylogenetically conservative." 3716. Johansson, F.; Brodin, T. (2003): Effects of fish predators and abiotic factors on dragonfly community structure. *Journal of Freshwater Ecology* 18(3): 415-423. (in English). ["We compared the community structure of odonates (Odonata) in 13 waters in northern Sweden, which differed with respect to fish presence and abiotic factors. Richness and abundance of odonates were estimated by collecting exuviae during the whole emergence season of 1999. Redundancy analysis revealed that fish presence influenced the community composition of the odonate larvae. While species richness per sample was not affected by the presence of fish, total abundance of odonates was higher in waters without fish. In waters with fish, *Aeschna juncea* and *Leucorrhinia dubia* showed lower abundances, whereas *Erythromma najas* and *Cordulia aenea* showed higher abundances. The abundances of *Coenagrion hastulatum*, *Libellula quadrimaculata*, and *Leucorrhinia rubicunda* did not differ between waters with and without fish. Of the six abiotic factors analyzed only water acidity was associated with odonate community structure." 3717. Johansson, F. (2003): Latitudinal shifts in body size of *Enallagma cyathigerum* (Odonata). *Journal of Biogeography* 30: 19-34. (in English). [Body size pattern for populations of *E. cyathigerum* across a south-north transect covering localities in Spain, Belgium, Sweden, and Norway was sampled. In total 253 newly emerged adults were collected from fourteen localities. "Body size was measured using thorax length, length of right front wing and length of right hind tibia. These body size estimates were thereafter related to latitude and mean temperature in January and July. Body size showed a U-shaped pattern with latitude, being large at low and high latitudes and small at intermediate latitudes. The same U-shaped pattern was found for mean January and July temperature, with large animals at low and high temperatures. The U-shaped relationship between body size and latitude is suggested to be a combination of two effects: (1) the length of the season favourable

for growth and development, and (2) variation in life cycle length with latitude." (Author)] Address: Johansson, F., Dept of Ecology and Environmental Science, Animal Ecology Group, Umea University, 90187 Limed, Sweden. E-mail: frank.johansson@eg.umu.se

3718. Jordan, S.; Simon, C.; Polhemus, D. (2003): Molecular systematics and adaptive radiation of Hawaii's endemic damselfly genus *Megalagrion* (Odonata: Coenagrionidae). *Systematic Biology* 52(1): 89-109. (in English). ["Damselflies of the endemic Hawaiian genus *Megalagrion* have radiated into a wide variety of habitats and are an excellent model group for the study of adaptive radiation. Past phylogenetic analysis based on morphological characters has been problematic. Here, we examine relationships among 56 individuals from 20 of the 23 described species using maximum likelihood (ML) and Bayesian phylogenetic analysis of mitochondrial (1,287 bp) and nuclear (1,039 bp) DNA sequence data. Models of evolution were chosen using the Akaike information criterion. Problems with distant outgroups were accommodated by constraining the best ML ingroup topology but allowing the outgroups to attach to any ingroup branch in a bootstrap analysis. No strong contradictions were obtained between either data partition and the combined data set. Areas of disagreement are mainly confined to clades that are strongly supported by the mitochondrial DNA and weakly supported by the elongation factor 1alpha data because of lack of changes. However, the combined analysis resulted in a unique tree. Correlation between Bayesian posterior probabilities and bootstrap percentages decreased in concert with decreasing information in the data partitions. In cases where nodes were supported by single characters bootstrap proportions were dramatically reduced compared with posterior probabilities. Two speciation patterns were evident from the phylogenetic analysis. First, most speciation is interisland and occurred as members of established ecological guilds colonized new volcanoes after they emerged from the sea. Second, there are several instances of rapid radiation into a variety of specialized habitats, in one case entirely within the island of Kauai. Application of a local clock procedure to the mitochondrial DNA topology suggests that two of these radiations correspond to the development of habitat on the islands of Kauai and Oahu. About 4.0 million years ago, species simultaneously moved into fast streams and plant leaf axils on Kauai, and about 1.5 million years later another group moved simultaneously to seeps and terrestrial habitats on Oahu. Results from the local clock analysis also strongly suggest that *Megalagrion* arrived in Hawaii about 10 million years ago, well before the emergence of Kauai. Date estimates were more sensitive to the particular node that was fixed in time than to the model of local branch evolution used. We propose a general model for the development of endemic damselfly species on Hawaiian Islands and document five potential cases of hybridization (*M. xanthomelas* X *M. pacificum*, *M. eudytum* X *M. vagabundum*, *M. orobates* X *M. oresitrophum*, *M. nesiotus* X *M. oahuense*, and *M. mauka* X *M. paludicola*)." 3720. Kalkman, V.J.; Wasscher, M.; Pelt. G.J. Van (2003): An annotated checklist of the Odonata of Turkey. *Odonatologica* 32(3): 215-236. (in English). ["In addition to the checklist, species of which the taxonomic status has changed, or with significant changes in the known distribution, are annotated. At present a total of 96 species (6 of which are divisible into 2 or more subspecies) are now known to occur in Turkey with certainty, and at least 15 species and an additional 5 subspecies are to be expected. *Ischnura fountainei* is new to the Turkish fauna. The sole Turkish record of *Ophiogomphus cecilia* pertains to *O. reductus* which is here mentioned for the first time from Turkish territory." (Authors)] Address: Kalkman, V.J., National Museum of Natural History, P.O. Box 9517, 2300 RA Leiden, The Netherlands. E-mail: kalkman@naturalis.nnm.nl

3721. Kauppinen, J.; Mappes, J. (2003): Why are wasps so intimidating: field experiments on hunting dragonflies (Odonata: *Aeshna grandis*). *Animal Behaviour* 66: 505-511. (in English). ["The mechanisms of aposematism (unprofitability of prey combined with a conspicuous signal) have mainly been studied with reference to vertebrate predators, especially birds. We investigated whether dragonflies, *Aeshna grandis*, avoid attacking wasps, *Vespula norvegica*, which are an unprofitable group of prey for most predators. As a control we used flies that were painted either black or with yellow and black stripes. The dragonflies showed greater aversion to wasps than to flies. Black-and-yellow-striped flies were avoided more than black ones, suggesting that aposematic coloration on a harmless fly provides a selective advantage against invertebrate predators. There was no significant difference in reactions to black-painted and black-and-yellow wasps, indicating that, in addition to coloration, some other feature in wasps might deter predators. In further experiments we offered dragonflies artificial prey items in which the candidate warning signals (coloration, odour and shape) were tested separately while other confounding factors were kept constant. The dragonflies avoided more black-and-yellow prey items than solid black or solid yellow ones. However, we found no influence of wasp odour on dragonfly hunting. Dragonflies were slightly, but not significantly, more reluctant to attack wasp-shaped prey items than fly-shaped ones. Our results suggest that the typical black-and-yellow stripes of wasps, possibly combined with their unique shape, make dragonflies avoid wasps. Since black-and-yellow stripes alone significantly decreased attack rate, we conclude that even profitable prey species (i.e. Batesian mimics) are able to exploit the dragonflies' avoidance of wasps." (Authors)] Address: Mappes, J., Dept of Biological and Environmental Science, University of Jyväskylä, P. O. Box 35, FIN-40014 University of Jyväskylä, Finland. E-mail: mappes@byl.jyu.fi

3722. Kemp, D.J.; Alcock, J. (2003): Lifetime resource utilization, flight physiology, and the evolution of contest

competition in territorial insects. *Am. Nat.* 162: 290-301. (in English). ["Adaptationist analyses of animal contests have contributed much to our understanding of behavioral evolution. One class of contest, however, the war of attrition, has proven difficult to interpret. In wars of attrition involving aerial displays, there is evidence that asymmetries in performance parameters such as flight energetics may be important determinants of contest resolution. This paradigm is not universal, however, and we presently lack a framework for understanding why certain biophysical parameters are important only in some cases. One possibility is that the relevance of these parameters is determined by evolutionarily conserved life-history-scale patterns of resource allocation and acquisition. We evaluated this hypothesis by investigating the correlates of competitive success in two territorial insects that exemplify markedly different lifetime patterns of resource utilization. We found that in the bot fly *Cuterebra austeni*, an extreme capital breeding species that depends entirely on energy acquired during its immature stages, territorial residency was most strongly correlated with a size-independent measure of energetic availability. In contrast, residency in the tarantula hawk wasp *Hemipepsis ustulata* was best predicted by variation in body size per se. Adult *H. ustulata* are able to supplement their larval-derived nutrient capital in the manner of an income breeder, and fuel reserves were independent of age and actually correlated negatively with residency in this species. These results underscore how the study of sexually selected phenomena may be enriched by an explicit consideration of life-history principles." (Authors) Odonata are discussed at several contexts.] Address: Alcock, J., Department of Biology, Arizona State University, Tempe, Arizona 85287-1501, USA. E-mail: j.alcock@asu.edu

3723. Ketelaar, R. (2003): Libellen vliegen vroeger en noordelijker: Een gevolg van klimaatverandering? *Levende Natuur* 104(3): 83-85. (in Dutch with English summary). ["Dragonflies are flying earlier and expanding northwards: An effect of climate change?: A balance of Dutch dragonflies in terms of changes in distribution shows that the number of increasing and decreasing species are approximately equal. However, it appears that species with a mainly southern distribution dominate the increasing group. The decreasing group consists mainly of more stenotopic species. Northern species generally decrease in The Netherlands. Not only changes in distribution are apparent, it is also shown that dragonflies have shifted their flight season. In an analysis for ten common species it is evidenced that for nine species the peak flight season is nowadays much earlier than in 1980, in some cases two weeks earlier. Climate change (especially warmer summers) is thought to be one of the driving factors behind these processes and this is shortly discussed." 3724. Klausnitzer, B. (2003): Gesamtübersicht zur Insektenfauna Deutschlands. *Entomologische Nachrichten und Berichte* 47(2): 57-66. (in German with English summary). [The "Entomofauna Germanica", presenting the first complete and up-to-date overview of the German insect fauna with a total of 1327 pages, documents 33466 species from 30 orders. A decline in species numbers from north to south is fairly striking, for example in Auchenorrhyncha, Heteroptera, Neuroptera,

Coleoptera and Hymenoptera. In almost all studied groups Bavaria is the federal state with the highest species numbers; Baden-Württemberg frequently holds second rank. According Müller & Schorr (2001), the Odonata contribute to the German fauna 80 species; in the meantime, *Boyeria irene* found in Bavaria, has to be added to the German check-list.] Address: Klausnitzer, B., Lannerstr. 5, D-01219 Dresden, Germany

3725. Kleukers, R.; Reemer, M. (2003): Veranderingen in de Nederlandse ongewerveldenfauna. *Levende Natuur* 104(3): 86-89. (in Dutch with English summary). ["Changes in the Dutch invertebrate fauna: Until now range changes in Dutch invertebrates were only documented for a few, large and conspicuous species, e.g. *Argiope bruennichi*, *Volucella zonaria* and *Phaneroptera falcata*. For the first time now a substantial part of the Dutch fauna was analysed, in a pilot study relying heavily on the expert judgement of the specialists of European Invertebrate Survey-The Netherlands. In total 1331 species of Apidae, Asilidae, Carabidae, Formicidae, Mollusca, Odonata, Orthoptera and Syrphidae were studied. In this paper we focus on the 339 species of which the northern border of the range runs through The Netherlands. No less than 101 species of this group have expanded their range to the north in the 20th century, especially in the groups Odonata, Syrphidae and Mollusca. In total 63 species were found to have retreated to the south, especially the Apidae. The expanding species of most groups are mainly eurytopic species, characteristic for disturbed, cultivated habitats. The declining species are mainly stenotopic species restricted to nature reserves. The Carabidae are an exception, as the expanding ground beetles seem to be mostly stenotopic." 3726. Knijf, G. de; Anselin, A.; Goffart, P. (2003): Trends in dragonfly occurrence in Belgium (Odonata). *Proc. 13th Int. Coll. EIS, September 2001(2003)*: 33-38. (in English). ["The group 'Gomphus' collected 65 000 records of 69 species of Odonata, more or less equally scattered over Belgium. The best-investigated areas are the northern part and some river valleys in the south. Most hot spots can be found in the northeastern part, with a maximum of 48 species for 25 km². Remarkable is the fact that 50% of the species occurs in less than 7% of the 5 km grid cells (UTM). We determined trends in occurrence by comparing three periods: before 1950, 1950-1989 and 1990-2000. Four species show a clear decline over the three periods, eight species give evidence of a historical decline but survive on a limited number of sites and eight species also display a historical decline but have been increasing during the last decade. Six species show a (very) clear increase over the three periods and two species display their increase only during the last ten years." 3727. Kühn, J.; Gutser, D. (2003): Beobachtung einer *Boyeria irene* bei Mittenwald, Oberbayern (Odonata: Aeshnidae). *Libellula* 22(1/2): 41-48. (in German, with English summary). [On 17 June 2002, a mature male of *B. irene* was watched extensively from little distance but could not be caught. It was hunting persistently on a clearance at an altitude of 1135 m (47°27,5'N 11°14'E),

southern Bavaria, Germany. This is the first observation of *B. irene* reported from Germany, and the 81th recorded odonate species in Germany. Possible immigration routes as well as the early date of the record are briefly discussed.] Address: Kuhn, J., Max-Planck-Institut für Verhaltensphysiologie, Abt. Winckler, D-82319 Seewiesen. E-mail: kuhn@mpi-seewiesen.mpg.de

3728. Lajeunesse, M.J.; Forbes, M.R. (2003): A comparison of structural size and condition in two female morphs of the damselfly *Nehalennia irene* (Hagen) (Zygoptera: Coenagrionidae). *Odonatologica* 32(3): 281-287. (in English). ["Female colour polymorphism in coenagrionid damselflies is genetically determined for the 4 species so far studied. No size differences between female morphs have been reported. In another species, size differences between morphs do exist but the genetic basis of the polymorphism has not been explored. In *N. irene*, 2 female morphs exist: one is similar to the male in both colour and pattern (the androchrome), whereas the other differs from the male (the more common gynochrome). No differences are shown in lengths of wing, femur or tarsus between androchromes and gynochromes, nor any differences in multivariate estimates of size or in wet mass corrected for these size estimates were found. The study controls for time of season, which is known to influence the size of emerging temperate damselflies. The results concur with results from other spp. where the genetic basis of colour polymorphism is known." 3731. Mackenzie, R.A.; Kaster, J.L. (2003): A preservative-free emergent trap for the isotopic and elemental analysis of emergent insects from a wetland system. *Great Lakes Entomologist* 35(1) (2002): 47-51. (in English). ["This study reports a cost-effective, live emergent trap designed for the preservative-free use in both biogeochemical and ecological analyses of emerging insects. The trap proved to be advantageous in several ways. First, the simple design made the trap time-efficient since it was easy to set-up, change, and maintain. Second, live sampling not only provided uncontaminated organisms for elemental and stable isotopic analyses, it minimized disfigurement. This resulted in rapid and easy handling, as well as identification, of adult insects. Finally, trap avoidance by ephemeropterans and odonates, a common problem encountered in the literature, was minimal and organisms from both insect orders were successfully collected." (Author)] Address: Mackenzie, R., The Center for Great Lakes Studies at the Water Institute, University of Wisconsin-Milwaukee, 600 E. Greenfield Ave., Milwaukee, WI, 53204, USA

3732. Maczey, N. (2003): *Calopteryx splendens* und Straßenverkehr - Beobachtungen an einer Autobahnbrücke (Odonata: Calopterygidae). *Libellula* 22(1/2): 15-18. (in German with English summary). ["In 1998, during a short period of fierce wind, more than 30 specimens of *C. splendens* were recorded as traffic victims alongside a motorway crossing the river Dosse in Brandenburg, Germany. This surprisingly high number demonstrates that - under certain circumstances - local insect populations may be negatively influenced by heavy traffic." 3733. Maeto, K.; Kougo, K.; Kotani, E.; Miyata, H.; Sugimura, M. (2003): Geographical analysis of Odonata habitats in the Shimanto River basin, Shikoku, Japan. *Japanese Journal of Entomology* 6(1): 27-41. (in Japanese with English summary). ["We conducted a correspondence analysis (CA) of 88 species of Odonata (dragonflies) observed at 455 grid sites (ca. 0.5 kmX0.5 km) in the Shimanto River basin and adjacent areas in Shikoku, Japan. Multiple regression analyses of the two main axes of the CA ordination on the geographical features (altitude, relief) and vegetation of grid sites indicated that the degree of relief and the areal proportion of paddy fields were the main determinants of the species distribution of Odonata. The species were classified into 5 groups by k-means clustering based on the coordinate axes. Groups I and II mostly consisted of lentic species inhabiting ponds, marshes and paddy fields of flat lands. Groups III and IV were composed of lentic species mainly inhabiting marshes and paddy fields and lotic species in slow streams. Group V consisted of lotic species inhabiting mountain streams and spring s. Habitat requirements for the species appearing in the Red List of Kochi Prefecture are also discussed." 3736. Marinov, M. (2003): Chorology, biological and habitatic comments of the insects from the genus Odonata in Bulgaria. PhD thesis, University of Sofia, Institute of Zoology: 196 pp., 4 app.. (in Bulgarian). ["It summarizes the results either published, state and private collections as well as original information by the author received during the whole 119-years period (1892-2001) of the development of the odonatology in Bulgaria. The thesis consists of 11 chapters. 1. INTRODUCTION. Short general description of the Order Odonata and reasons for using dragonflies as subject of the investigation. 2. PHYSICO-GEOGRAPHIC REVIEW OF BULGARIA. Consequently situation, state borders, territory area, relief, geology and geomorphology, climate and water resources of Bulgaria are developed as abiotic factors influencing Odonata distribution pattern in Bulgaria. 3. ODONATOLOGICAL INVESTIGATIONS IN BULGARIA. Three periods are outlined according to the number of the publications published per year and the main contributions. Dragonflies are considered as well faunistically investigated insect group in Bulgaria. The main gaps are in regional investigations, species ecology and biology, dragonfly utility as bioindicators, population investigations. 4. GOALS AND OBJECTIVES. 5. MATERIAL AND METHODS. 6. RESULTS. Here each species is given with individual information about: 1) synonym list; 2) faunistical and taxonomic problems (if any); 3) biology and ecology (what is known for Bulgaria); 4) overall species distribution mapped for Europe and referenced for the rest of the area; 5) UTM map for the species' distribution in Bulgaria; 6) phenology and vertical distribution graphs. 7. DISCUSSION. Comments are given on the species' phenology, zoogeographic affiliation, distribution according to the main biotopes and habitats in Bulgaria as well as individual position in the First Conservation List developed for Bulgarian Odonata species. 8. CONCLUSIONS. Fourteen conclusions represent the main contributions made to the studying of Bulgarian Odonata fauna. 9. DEDUCTIONS. Fifteen deductions are given. They point the attention to some problems not solved during the current investigation and are given as some of the main tasks for future investigations. 10. REFERENCES. 11. ACKNOWLEDGEMENTS." 3737. Masius, P. (2003): *Nehalennia speciosa* auf der Insel Usedom (Odonata: Coenagrionidae). *Libellula* 22 (1/2): 1-14. (in German with English summary). [In June 2001 the *N. speciosa* was recorded at a bog south of Ahlbeck, Island of Usedom, Mecklenburg-Vorpommern, Germany. The habitat is briefly described, and co-occurring odonate species are given.] Address: Masius, P., Erlanger Straße 69, D-95444 Bayreuth, Germany. E-Mail: Snoopy123dag@gmx.net

3738. May, M.; Corbet, P. (2003): Gathering useful information about the seasonal ecology of *Anax junius*. *Argia* 15(2): 15-16. (in English). ["A large question mark hangs over the movements and destination of adults of *Anax junius* after they fly southwards from southern Canada and northern states of the US in fall. Likewise, little is known about the northernmost latitude in North America at which resident populations of larvae can overwinter. It is likely to take a very long time if such information is going to be accumulated solely by chance observations. Much better that a planned survey could be undertaken that offers a high likelihood of early success. The knowledge that some populations of *A. junius* (occupying the same pond) have two components, one resident and one migratory, derives from a classic study by Robert Trotter in southern Ontario (Trotter 1971). [...] John Matthews, who is a student of John Abbot's at the Univ. of Texas, is currently looking ponds in Ontario, where Trotter worked, and in Texas. This approach has a lot of potential, despite its difficulties. I'm pretty sure that no one has studied the life history of any odonate species over a latitudinal and climatic range as great as that of *A. junius*, and no one has tied in phenology over such a range with migratory behavior. There's a chance to do something pretty unique here, if people can help us find additional suitable sites or even, if you're really interested and like working in mucky places on baking hot and miserably cold days, helping with." 3739. McKee, D.; Harvey, I.; Thomas, M.; Sherratt, T.N. (2003): Mite infestation of *Xanthocnemis zealandica* in a Christchurch pond. *New Zealand Jour. Zool.* 30 (1): 17-20. (in English). ["Infestation of the common red-coat damselfly *Xanthocnemis zealandica* (McLachlan) with larval water mites (*Arrenurus* spp.) was examined in a single Canterbury population during November-December 2001. Teneral (immature adult damselflies) of both male and female morphs (androchrome and gynochrome) showed a similar prevalence of infestation, higher than the prevalence of infestation found in mature adults. As anticipated, mature adult males were more frequently infested than mature females, but there was no evidence that infestation reduced the mating activity of males. Up to 62 mites were found per infested host, although mean mite burdens were not significantly related to the size, gender or morph of the hosts." (Authors)] Address: McKee, D., School of Biological and Biomedical Sciences, University of Durham, Durham, DH1 3LE, UK. E-Mail: dermot.mckee@durham.ac.uk

3740. Mead, K. (2003): *Dragonflies of the North Woods*. Kollath-Stensaas Publishers. ISBN 0-9673793-6-9. 212 pp. (in English). [This attractive and very useful field guide covers the "northwoods" areas of Minnesota, Wisconsin, Michigan (USA), and western Ontario (Ca-

nada). It treats 102 Anisoptera only, except that six of the most common damselflies are illustrated and briefly described. This book can be assessed as an advanced field guide, that focus on identifying Anisoptera, and that goes beyond descriptions of species; it dwells on the problems of distinguishing similar species. Two pages are devoted to the thoracic patterns of *Aeshna*, showing color variants, followed by 30 additional pages on the Aeshnidae (they must be a favorite group of Kurt Mead). A second focus was set on the genus *Leucorhinia* with many useful advices for correct identification of the different stages of the very species. Fieldmark arrows point out the best distinguishing characteristics. Size-bars on the colour photos show the dragonfly's actual body length. This guide is very well illustrated with excellent - app. 200 - photographs. Throughout the text there are thoughtful and provocative behavioural observations, which will guide the user to becoming a good observer and not just an identifier. In addition you will find between the lines some useful information how to swing your net ... Quite unique is a chapter entitled "Binoculars for 'Dragonflying'"; binoculars are listed brand-wise with dates enabling persons interested in buying one for dragonflying to make a useful pre-selection. This is an excellent guide, with a didactical concept that could be interesting for other countries too. (Martin Schorr) Address: Mead, K., 6388 Lax Lake Rd., Finland, MN 5560, USA. <http://www.dragonfliesofthenorthwoods.com/>

3741. Meßlinger, U.; Winterholler, M. (2003): Bestandssituation und Ökologie von *Coenagrion lunulatum* in Franken (Odonata: Coenagrionidae). *Libellula Supplement 4*: 43-58. (in German, with English summary). [Between 1986 and 1995, 25 records of *C. lunulatum* have been documented for Bavaria between 1986 and 1995. In the following years, the species could be confirmed only at three localities. At one of these habitats further investigations regarding water chemistry, vegetation and biology of the species were carried out between 1998 and 2003. Effects of climatic change are discussed as a possible reason for the dramatic decline of *C. lunulatum* within Bavaria.] Address: Meßlinger, U., Am Weiherholz 43, D-91604 Flachslanden, Germany. E-Mail: u.messlinger@t-online.de

3742. Meßlinger, U.; Faltin, I. (2003): Verbreitung und Ökologie von *Coenagrion ornatum* in Westmittelfranken (Odonata: Coenagrionidae). *Libellula Supplement 4*: 19-42. (in German, with English summary). [On the basis of confirmed indications for a regional distribution of *C. ornatum*, in the year 2001 a full-coverage search for the species was carried out in western Middle Franconia. "Altogether 734 creek and ditch sections were visited, and *C. ornatum* was recorded at 55 of those waters. The core population discovered in 1997 in the upper River Altmühl valley extended over 28 sites, being one of the greatest populations of the species within Bavaria. In the catchments of the Rivers Zenn, Wörnitz, Wieseln, Sulzach and Tauber *C. ornatum* was reported for the first time. All populations along these rivers were small or very small. A presentation of the current regional distribution of the species is given. Essential factors of habitat and the influence of the management of inhabited waters and adjacent meadows are discussed. The results of the study indicate knowledge gaps concerning the actual distribution of *C. ornatum*, emphasizing the probability of undiscovered populations in hitherto insufficiently investigated running water systems outsi-

de western Middle Franconia." (Authors)] Address: Meßlinger, U., Am Weiherholz 43, D-91604 Flachslanden, Germany. E-Mail: u.messlinger@t-online.de

3743. Mirza, R.S.; Chivers, D.P. (2003): Influence of body size on the responses of fathead minnows, *Pimephales promelas*, to damselfly alarm cues. *Ethology* 109(8): 691-699. (in English). ["A wide diversity of aquatic organisms release chemical alarm cues upon encountering or being attacked by a predator. These alarm cues can be used by nearby individuals to assess local predation risk. Receivers warned by chemical alarm cues gain a survival benefit when encountering predators. Animals that are in the same prey guild (i.e. that co-occur and share the same predators) may learn to recognize each others' chemical alarm cues. This ability may confer an adaptive advantage if the prey animals are vulnerable to the same predators. However, if the prey grow to different sizes and as a consequence are no longer vulnerable to the same suite of predators, then there should no longer be an advantage for the prey to respond to each others' alarm cues. In this study, we exposed small and large fathead minnows (*Pimephales promelas*) to cues from syntopic injured damselfly larvae (*Enallagma boreale*), cues from injured mealworm larvae (*Tenebrio molitor*) and to distilled water. Small minnows exhibited antipredatory behaviour and increased shelter use in response to injured damselfly cues but not to the controls of injured mealworm or distilled water. On the contrary, large minnows exhibited no significant change in shelter use in response to any of the injured cues. These data demonstrate that fathead minnows exhibit an antipredator response to damselfly alarm cues, but only when minnows are small and members of the same prey guild as damselfly larvae. These results demonstrate the considerable flexibility in the responses to heterospecific alarm cues." (Authors)] Address: Mirza, R.S., Dept of Biology, Pennsylvania State University, 208 Mueller Laboratory, University Park, PA, 16802, USA. E-Mail: rsm12@psu.edu

3744. Montero Moreno, J.R. (2003): A note on *Thaumatoneura inopinata* McLachlan 1897 in Rio Chiarria Costa Rica with a list of Costa Rican Megapodagrionidae. *Argia* 15(1): 17. (in English). [*T. inopinata* was recorded twice along waterfalls of Rio Chiarria near Turrialba in Feb. 1998 and in Oct. 1999.] Address: Montero Moreno, J.R., P.O. box 1913-1000, San Jose, Costa Rica

3745. Morales, M. E.; Wesson, D.M.; Sutherland, I.W.; Impoinvil, D.E.; Mbogo, C.M.; Githure, J.I.; Beier, J.C. (2003): Scientific note determination of *Anopheles gambiae* larval DNA in the gut of insectivorous dragonfly (Libellulidae) nymphs by polymerase chain reaction. *Journal of the American Mosquito Control Association* 19(2): 163-165. (in English). ["We examined the predator-prey relationship between larvae of the malaria mosquito *Anopheles gambiae* and nymphs of the dragonfly (Libellulidae). Studies were conducted to determine whether polymerase chain reaction (PCR) can be used to detect DNA of *An. gambiae* in the gut of libellulid nymphs, and to determine how long after feeding on *An. gambiae* that mosquito DNA remains detectable by PCR. Total DNA was extracted from the gut contents of libellulid nymphs by using 2 types of DNA extraction methods. The target sequence for the diagnostic PCR was the intergenic spacer regions of the ribosomal DNA gene locus. These sequences were analyzed by using

An. gambiae complex-specific primers. After analyzing nymphal gut contents with PCR at regular postfeed intervals, a 390-base pair product could be amplified. The presence of mosquito larvae was visually confirmed for up to 40 min after feeding. Regardless of the number of mosquito larvae ingested, libellulid gut contents could be amplified or visually seen up to 1 h of digestion. This result indicates the nymphs have a high rate of digestion and that PCR with An. gambiae complex primers will be best utilized within 1 h after feeding as a detection system. This study confirmed that dragonfly nymphs feed well on anopheline larvae, and that mosquito DNA, although rapidly digested, can be successfully recovered and detected from within nymphal digestive tracts." (in German, with English summary). ["A. caerulea was monitored in the years 2000 and 2001 in the Allgäu Alps of the Bavarian Oberallgäu District, the distribution centre of the species within Bavaria and Germany. Thirty-one potential breeding habitats in subalpine bogs and minerotrophic ponds were

investigated. At altitudes between 1190 m and 1840 m above sea level the species was recorded at 16 localities. The bog and water types inhabited by A. caerulea in the region are characterized. Current populations and potential threats to the species by grazing cattle, wallowing red deer, and climate changes are discussed." 3752. Ogden, T.H.; Whiting, M. (2003): Genomic tissue library of Odonata: A call for specimens. Argia 15(2): 20-21. (in English). [Website: <http://odonata.byu.edu>; "... We have two immediate purposes for the obtained odonate specimens. First we want to investigate the relationships of the basal pterygote lineages (Ephemeroptera, Odonata, and Neoptera). The phylogenetic position of Odonata among the other orders has been controversial, and three main theories exist: (1) placement as sister group to Ephemeroptera (=Paleoptera); (2) placement as the most basal pterygote lineage; and (3) placement as sister to Neoptera. Second, we plan to address the higher-level phylogeny of Odonata using DNA sequence information combined with morphological data. Our goal, for the next year, is to sequence a wide range of exemplar taxa for multiple genes (~ 8 markers), combine this information with morphological data (collaboration with Andy Rehn), and use these data to gain new insights into odonate systematics and evolution. [...]" (Authors)] Address: T. 3753. Ogden, T.H.; Whiting, M.F. (2003): The problem with "the Paleoptera Problem:" sense and sensitivity. Cladistics 19(5): 432-442. (in English). ["While the monophyly of winged insects (Pterygota) is well supported, phylogenetic relationships among the most basal extant pterygote lineages are problematic. Ephemeroptera and Odonata represent the two most basal extant lineages

of winged insects, and determining their relationship with regard to Neoptera (remaining winged insects) is a critical step toward understanding insect diversification. A recent molecular analysis concluded that Paleoptera (Odonata + Ephemeroptera) is monophyletic. However, we demonstrate that this result is supported only under a narrow range of alignment parameters. We have further tested the monophyly of Paleoptera using additional sequence data from ISSrDNA, 28S rDNA, and Histone 3 for a broader selection of taxa and a wider range of analytical methodologies. Our results suggest that the current suite of molecular data ambiguously resolve the three basal winged insect lineages and do not provide independent confirmation of Odonata + Neoptera as supported via morphological data." 3754. Orr, A.G. (2003): A guide to the dragonflies of Borneo: Their identification and biology. Natural history publications (Borneo). Kota Kinabalu. ISBN 983-812-069-3. 195 pp. (in English). [With 275 named species so far recorded and doubtless many more yet to be discovered, Borneo has one of the richest and most exciting dragonfly faunas in the world. More than 40% of species occur nowhere else, making it the most distinctive sub-region of Sundaland. It is home to such spectacular species as *Tetracanthagyna plagiata*, the heaviest of all dragonflies, many beautiful picture-winged chlorocyphids and euphaeids, and high-altitude endemics such as *Matronoides cyaneipennis* restricted to Mount Kinabalu and nearby mountains. Species are figured by photographs, generally taken in nature, and half-wing coloured drawings (25 plates). Many are figured by both methods. About 60% of known species are shown, including almost all the distinctive and common species likely to be encountered by a casual visitor. Particular attention is given to the identification of the common but difficult medium-sized red dragonflies. The text augments the illustrations and provides - family- and species-wise - useful information on biology. Introductory chapters discuss structure and general biology, ecology and conservation, faunistics and biogeography and collecting techniques and photography. There is a complete and up to date checklist. Illustrated keys to families of adults give the reader an understanding of the structures used in classifying dragonflies and augment the usefulness of the illustrations of entire insects. Main larval forms are shown.] Address: Natural history publications (Borneo) SDN. BHD. A913, 9th Floor, Phase 1, Wisma Merdeka, P.O. 3761. Purse, B.V.; Hopkins, G.W.; Day, K.J.; Thompson, D.T. (2003): Dispersal characteristics and management of a rare damselfly. *Jour. Appl. Ecol.* 40: 716-728. (in English). ["1. *Coenagrion mercuriale* is a rare damselfly in Britain and mainland Europe and has been declining in the last 30 years. It has specialized habitat requirements and has been viewed, traditionally, as a poor disperser. Knowledge of its dispersal ability was considered in its Biodiversity Species Action Plan as essential for the formulation of appropriate conservation management strategies. 2. Mark-release-recapture studies of *C. mercuriale* in two large UK heathland popula-

tions were undertaken. Mature adults had a low rate of movement within continuous areas of habitat (average < 25 m movement), low emigration rates (1-3-11 -4%) and low colonization distances (maximum 1 km), all comparable to similarly sized coenagrionids. 3. Movements were more likely within than between patches of suitable habitat over short to medium distances (50-300 m). Between-patch movements were more likely between patches that were close together. Scrub barriers reduced dispersal. 4. The probability of dispersal between two recaptures depended on the length of the time interval between them. *C. mercuriale* performed considerable between-patch movements within a small fraction (1-2 days) of its mean mature adult life span (7-8 days). 5. Qualitative comparison of field colonization distances measured here and distances between UK sites occupied by *C. mercuriale* revealed that empty sites within large clusters of sites would probably be recolonized rapidly and dispersal events would be frequent. However, such events would occur rarely within small isolated sites or clusters of sites, leaving local populations prone to extinction. 6. Synthesis and applications. These data show that management effort should be directed towards maximizing the likelihood of *C. mercuriale* recolonizing sites naturally within 1-3 km of other populations (particularly within large clusters). Scrub boundaries should be removed between existing populations and empty, but suitable, sites to facilitate stepping-stone dispersal movements." 3762. Purse, B.V.; Thompson, D.J. (2003): Emergence of the damselflies, *Coenagrion mercuriale* and *Ceragrion tenellum* (Odonata: Coenagrionidae), at their northern range margins, in Britain. *Eur. J. Entomol.* 100: 93-99. (in English). ["Emergence of *Coenagrion mercuriale* and *Ceragrion tenellum* was examined in a mixed population at their northern range margin in Britain. Mortality at emergence was quantified in *C. mercuriale*. Consistent with their larval diapause characteristics, both species had an asynchronous emergence pattern, typical of "summer" species. Daily emergence of *C. mercuriale* was positively correlated with the duration of sunlight on the previous day (controlling for season) and its emergence period was found to be shorter than that observed in its core populations in Central and Mediterranean Europe. No differences were found between the patterns of emergence of the sexes in either species. Sex ratio at emergence differed significantly from 1:1 (at 1.35 : 1 -males : females) in *C. mercuriale* but not in *Ceragrion tenellum* (at 1.04 : 1). Body size at emergence declined more steeply with time in females than in males of *C. mercuriale* because large size may confer a greater reproductive advantage in females (larger females may be more fecund) than males in non-territorial odonates. Percentage mortality of *C. mercuriale* at emergence was low (4.9% including deformed individuals), the main cause of mortality being deformity." 3766. Relyea, R.A. (2003): How prey respond to combined predators: a review and an empirical test. *Ecology* 84(7): 1827-1839. (in English). ["Studies of phenotypic plasticity frequently ask how organisms respond to a change in their environment, but most organisms do not experience single environmental changes. Therefore, we need to move to the next step and understand how organisms respond to combinations of environmental changes. Recent studies of predator-induced plasticity have addressed how prey respond to different combinations of predators. I briefly review 22 studies of combined predator effects on prey phenotypes and identify four factors that make it difficult to interpret the results of these studies: (1) uncontrolled prey consumption, (2) a low number of prey traits, (3) a low number of predator combinations, and (4) confounded predator composition and total predator density. I address these challenges in an experiment that examined how wood frog tadpoles (*Rana sylvatica*) altered 12 behavioral, morphological, and life historical traits in response to four different caged predators ("*Erythemis* sp.", *Belostoma*, *Dytiscus*, and *Anax junius*). The predators were present alone at low density, alone at high density (2X), or combined into six pairwise combinations. When each predator was alone (at either low < or high density), tadpoles discriminated among different predators and produced predator-specific phenotypes. The doubling of predator density rarely induced more extreme prey phenotypes. When predators were combined, the tadpoles generally developed phenotypes that were similar to those induced by the more risky predator alone (90% of all traits examined, at either low or high density). These results suggest that tadpoles per-

ceive the risk of combined predators as being similar to the risk of the most dangerous predator in the pair, and not as a summed or averaged predation risk. The actual risk from these predator combinations remains to be tested. This appears to be the first study to take a comprehensive approach that controls prey consumption, examines a large number of prey traits, uses a large number of predator combinations, and separates the effects of predator composition and predator density. There is a clear need for more such studies to determine whether these results can be generalized to other taxa." (Author)] Address: Relyea, R.A., Dept Biol. Sciences, University of Pittsburg, Pittsburgh, Pennsylvania 15260, USA. E-mail: relyea@pitt.edu

3767. Relyea, R.A. (2003): Predators come and predators go: the reversibility of predator-induced traits. *Ecology* 84(7): 1840-1848. (in English). ["While numerous studies have been conducted on the ecology and evolution of phenotypic plasticity, to really understand plasticity we need to expose organisms to different environments over several ontogenetic stages. In this way, we can examine whether organisms change their phenotypic strategy over ontogeny, whether there are developmental windows that constrain the development of plastic traits, and whether behavior is more reversible than morphology if the environment reverts back to its original state. I addressed these questions by examining predator-induced plasticity in gray treefrog tadpoles (*Hyla versicolor*). Using aquatic mesocosms, I reared tadpoles with a constant absence of predators, a constant presence of predators (*Anax longipes*), and the addition or removal of predators at three different times during their larval period. Tadpoles changed their phenotypic strategy over ontogeny; early in ontogeny they responded to predators by hiding, reducing their activity, and developing relatively deep tail fins. Later in ontogeny the tadpoles no longer employed behavioral defenses but relied on a combination of greater mass, deeper tails, and shorter bodies. The phenotypic changes were inducible throughout most of ontogeny, suggesting that there were few developmental windows. Activity, tail depth, and body depth were highly reversible early in ontogeny but less reversible later in ontogeny; because hiding was only used early in ontogeny, I could not assess its reversibility. This reversibility should affect not only the induced species, but will likely transmit the effects throughout the larger ecological community." (Author)] Address: Relyea, R.A., Dept Biol. Sciences, University of Pittsburg, Pittsburgh, Pennsylvania 15260, USA. E-mail: relyea+@pitt.edu

3771. Sirot, L.K.; Brockmann, H.J.; Marins, C.; Muschett, G. (2003): Maintenance of a female-limited polymorphism in *Ischnura ramburi* (Zygoptera: Coenagrionidae). *Animal Behaviour* 66: 763-775. (in English). ["Colour" polymorphisms can be maintained in a population if all morphs have equal fitness on average, if fitness is frequency dependent or if fitness functions cross for some environmental or social variable. We studied female-limited colour polymorphism in the Rambur's fork-tail damselfly, *Ischnura ramburi*, in which one female morph looks like the male. The most commonly cited hypotheses to explain this polymorphism involve an advantage to andromorphs of avoiding costly matings through male mimicry. An alternative hypothesis argues that males learn the most common morph and that the polymorphism is maintained by a rare-morph advantage of mating avoidance, irrespective of male mimicry. We tested predictions of the male mimicry hypothesis, learned mate recognition hypothesis (LMR) and two new hypotheses. We used censuses and a mark-resight study to estimate density, sex ratio, morph frequency and mating frequencies. We observed interactions to test for male mimicry and female competition and to evaluate the frequency of mating attempts. Andromorphs were less likely than gynomorphs to receive mating attempts in encounters with males, but did not mate less frequently, or attack males or interrupt oviposition by other females more frequently. Contrary to the LMR hypothesis, the rarer morph was more likely to receive mating attempts. Andromorph frequency was greater in older females than in younger females, suggesting higher mortality or dispersal of gynomorphs. Our results support a modification of the male mimicry hypothesis, the signal detection hypothesis. Together with past studies, our results suggest that the female morphs may be alternative mating avoidance strategies." 3774. Stoks, R.; McPeck, M.A.; Mitchell, J.L. (2003): Evolution of prey behavior in response to changes in predation regime: damselflies in fish and dragonfly lakes. *Evolution* 57(3): 574-585. (in English). ["In a large behavioral experiment we reconstructed the evolution of behavioral responses to predators to explore how interactions with predators have shaped the evolution of their prey's behavior. All *Enallagma* damselfly species reduced both movement and feeding in the presence of coexisting predators. Some *Enallagma* species inhabit water bodies with both fish and dragonflies, and these species responded to the presence of both predators, whereas other *Enallagma* species inhabit water bodies that have only large dragonflies as predators, and these species only responded to the presence of dragonflies. Lineages that shifted to live with large dragonflies showed no evolution in behaviors expressed in the presence of dragonflies, but they evolved greater movement in the absence of predators and greater movement and feeding in the presence of fish. These results suggest that *Enallagma* species have evolutionarily lost the ability to recognize fish as a predator. Because species coexisting with only dragonfly predators have also evolved the ability to escape attacking dragonfly predators by swimming, the decreased predation risk associated with foraging appears to have shifted the balance of the foraging/predation risk trade-off to allow increased activity in the absence of mortality threats to evolve in these lineages. Our results suggest that evolution in response to changes in predation regime may have greater consequences for characters expressed in the absence of mortality threats because of how the balance between the conflicting demands of growth and predation risk are altered." (Authors)] Address: McPeck, M., Dept Biol. Sci., Dartmouth College, Hanover, New Hampshire 03755, USA. E-mail: mark.mcpeek@dartmouth.edu

3775. Stoks, R.; McPeck, M.A. (2003): Predators and life histories shape *Lestes* damselfly assemblages along a freshwater habitat gradient. *Ecology* 84(6): 1576-1587. (in English). ["Survey data from New England showed that assemblages of *Lestes* damselflies are organized along the entire gradient of pond permanence and predator presence. One assemblage occupies vernal ponds lacking large dragonfly predators and fish; four are largely confined to temporary ponds that typi-

cally contain dragonfly predators; one dominates fishless permanent ponds and lakes where dragonflies are the top predators; and one dominates permanent ponds and lakes where fish are the top predators. We determined the role of life history and predation in maintaining this striking pattern by conducting a series of transplant experiments in the field and a laboratory experiment manipulating presence and absence of local predators. Life history (1) shaped the ability of species to cope with drying regime, thereby excluding temporary-pond *Lestes* from vernal ponds and permanent-water *Lestes* from temporary ponds, and (2) generated size differences among species due to differences in the timing of hatching. This mediated the exclusion of temporary-pond *Lestes* from permanent water bodies through asymmetric intraguild predation by permanent-water *Lestes*. Dragonfly predation on permanent-water *Lestes* had an indirect positive effect on the survival of temporary-pond *Lestes*; however, this effect apparently is too small to allow coexistence of both *Lestes* groups. Predation by large dragonfly larvae excluded the *Lestes* species of vernal ponds from temporary ponds, and differential vulnerability to large dragonfly larvae and fish shaped the reciprocal dominance of *L. eurinus* and *L. vigilax* in fishless and fish-containing permanent water bodies, respectively. Taken together, these results show that life history constraints and predation both shape the distributions of *Lestes* species along the pond permanence gradient in New England. We discuss the importance of this freshwater habitat gradient in shaping local and regional species diversity." 3776. Suhling, F.; Richter, O. (2003): Mathematical modeling of priority effects and intraguild predation with applications to Namibian Odonata populations. *Verhandlungen der Gesellschaft für Ökologie* 33: 169. (in English). [Verbatim: The model presented in this paper allows the study of the survival of populations in dependence on the intensities of cannibalistic interactions and intraguild predation, on the density of unspecific prey, on specific growth rates, and on temporal priority in colonization. Moreover, we study the question under which circumstances populations of predators may coexist. The parameter values used in this study are mainly derived from ongoing laboratory and field studies on the dragonfly assemblage of temporary freshwater ponds in the Namibian semi-desert. These assemblages may consist of up to about 25 species, mostly of the family Libellulidae, of which, however, only about ten species colonize temporary pools, i.e. lay eggs. Although all successful colonizers show rapid development some, such as *Pantala flavescens* and *Sympetrum fonscolombii*, grow faster than others, e.g. *Trithemis kirbyi* and *Crocothemis erythraea*. Our model includes age and size structure in form of partial differential equations, which is a compromise between simplistic model approaches in form of ordinary differential equations and individual based models. The classical model for the development of size structured populations based on a partial differential equation for the size density distribution as a function of time was extended to include cannibalism, intraguild predation among two populations and foraging behaviour in form of size dependent functional response curves. The mathematical formulation of intra- and interspecific predator prey interactions in size-structured populations lead

to integrals taking into account the interaction of all possible combinations of size classes. Introducing predation and cannibalism into the model leads thus to a system of coupled integro-differential equations, which are solved numerically by finite difference techniques. Models of this form possess a well-defined mathematical structure and are capable of capturing essential aspects of the interaction of age or size-structured populations. Figure 1 one shows as an example of model behaviour the effect of a "cohort splitting" occurring under shortage of nutrient resources due to intraspecific cannibalism. In this case, large larvae prey on small larvae of the same population and are thus able to survive and develop. The analysis of the model behaviour leads to the following conclusions 1. Cannibalism is a decisive factor of survival under scarce nutrition resources 2. Age cohorts of populations of different growth rates do not coexist under scarce nutrient resources 3. Foraging behaviour determines the window of opportunity for coexistence.] Address: Richter, O., Institute for Geocology, Technical University of Braunschweig, Germany. E-mail: o.richter@tu-bs.de

3777. Suhling, F.; Padeffke, T.; Johansson, F.; Richter, O. (2003): Mechanisms creating odonate community structure in desert wetlands. *Verhandlungen der Gesellschaft für Ökologie* 33: 282. (in English). [Verbatim: Temporary ponds in the Namibian semi-desert may be visited by a large number of dragonfly species even if the ponds are widely isolated from other aquatic habitats. At artificial ponds we identified 26 species, of which, however, only some colonised the ponds, i.e. laying eggs. The colonisers can be separated into two major groups. Group 1 consists of residents in the area, such as *Trithemis kirbyi* or are facultative migrants entering the area in small numbers, e.g. *Crocothemis erythraea* and *Orthetrum chrysostigma*. Species of group 2 are obligate migrants, which perform often long distance dispersal, normally in large aggregations, as obligate part of their life cycle [1], e.g. *Pantala flavescens* and *Sympetrum fonscolombii*. During two successive years almost exclusively migrants emerged successfully from the artificial ponds. Studies with early stadium larvae revealed that larvae of the migrants (group 2) are more active and have higher food intake than larvae of group 1; consequently the initial growth of the migrants was faster [2]. Fast growths allow species of group 2 to develop successfully under the conditions of temporary wetlands with short duration. Moreover, differences in growth should affect the outcome of interspecific interactions because size differences are the major driver for intraguild predation in dragonfly larvae [3, 4]. We tested the hypothesis that the larvae of the migrant *S. fonscolombii* grow faster and will be the superior predator to the larvae of the resident *T. kirbyi* when the eggs of both species are laid at the same time and place, because size differences of two or more instars will cause an increased mortality due to predation in a two-species interaction experiment [5]. We found that under these conditions *T. kirbyi* became almost extinct. However, the interaction between migrants and residents may also be altered by temporal differences in oviposition at a given habitat, i.e. temporal priority. At our artificial ponds we observed first ovipositions of *T. kirbyi* 11 days before those of *S. fonscolombii*. We therefore tested the hypothesis that the species that arrives first at the water (i.e. has temporal priority) is a superior predator to the later arriving species. We found that *T. kirbyi* survives and even dominates the competitive superior *S. fonscolombii* when the latter was introduced to the system 11 days later than *T. kirbyi*. 3778. Switzer, P.V.; Eason, P.K. (2003): Space use in territorial amberwing dragonflies: are residents female maximizers or neighbor minimizers?. *Behavioral Ecology and Sociobiology* 54(4): 321-328. (in English). [Residents of mating territories interact with different categories of conspecifics: females, nonneighbor males, and neighbor males. Interaction with these different types of conspecifics is likely to have different costs and benefits; for example, interactions with females will be beneficial, while interactions with neighbors are more likely to be costly. In this study, we investigated patterns of intrusions and space use in territorial male amberwing dragonflies (*Perithemis tenera*) to test the idea that residents will adjust their use of space to maximize their beneficial interactions with conspecifics while minimizing their costly interactions with conspecifics. Because territories were arranged linearly around the edge of a pond, each resident had two neighbors, one of which was often closer to the focal resident than the other. Residents experienced more intrusions by neighbors and fewer intrusions by females on the side of their closer neighbor. Residents generally perched on the side of their territory that experienced the fewest intrusions by neighbors and the most intrusions by females, but the pattern was more strongly related to neighbor intrusions than female intrusions. Subsequent to pursuits of neighbors and females, residents tended to shift their perches away from where they pursued neighbors but toward where they pursued females. Nonneighbor intrusions were not affected by neighbor proximity, nor did residents adjust their space use in response to nonneighbor intrusions. Our results suggest that residents do adjust their space use in response to intrusions by conspecifics, that their adjustment depends on the type of conspecific that intruded, and that residents may be using a simple decision rule such as "move away from male intrusions, move closer to female intrusions" to adjust their within-territory space use.] (Authors)] Address: Switzer, P.V., Eastern Illinois Univ., Dept Biol, Sci., Charleston IL 61920; USA. [Sachsen, Germany; 13 water bodies of different trophic level were surveyed in 1999 and 2000. A total of 30 odonate species was recorded, including several rare species. *Lestes virens*, *Coenagrion hastulatum*, *Aeshna affinis*, *Cordulegaster boltonii*, *Orthetrum coerulescens*, *Leucorrhinia albifrons*, *L. rubicunda*, and *L. dubia* are dis-

cussed in detail.] Address: Sy, T., RANA-Büro für Ökologie und Naturschutz, Am Kirchtor 27, D-06108 Halle (Saale), Germany

3780. Taylor, J. (2003): Backyard dragonflies in Perth. *Austrolestes* 7: 4. (in English). [Australia; "Two years ago we moved to our present house in the western suburbs. It has a large swimming pool in full sun that has not been turned into a dragonfly pond as yet. This summer I had the idea that I could make the pool dual purpose -pool and pond. At the beginning of February I purchased a pair of kiddies plastic pool/sandpits in the form of scallop shells and floated them in the pool. They were not stable, so I tied rubber foam pipe insulation around the edge, to hold them level while swimmers used the pool. The ponds were filled with tap water and I added some lilies and material netted from local lakes to seed them with pond fauna. Initially there was a problem with midge and mosquito larvae, but these were soon controlled with a few gambusia fish. The fish are no longer needed, since there are now ample insect predators. I don't know how much these ponds have influenced visiting dragonflies - but there are always dragonflies present and almost every day in late March and early April I have seen mating pairs laying eggs in the ponds."; *Orthetrum caledonicum*, *Diplacodes haematodes*, *Hemicordulia australiae*, *H. tau*, *Trapezostigma stenoloba*, *Pantala flavescens*, *Hemianax papuensis*, *Ischnura aurora*, *Xanthagrion erythroneurum*. "It is interesting that in the early stages of the ponds, dragonflies did not seem to recognise them as being any better than the pool for laying eggs in. But now they lay there almost exclusively. *Xanthagrion* persistently tried to lay on the creepy crawly pipe, *Hemicordulia* lays anywhere, even on glazed tiles. *Trapezostigma* makes a single plunge to dip its abdomen into the pool and then flies off. [...]". This pool is compared with a shady pool overhung by a huge gum tree. "When going out at night with a torch to look for emerging adults I found that *Hemianax* larvae have an interesting nocturnal behaviour of gently jetting themselves through open water over two metres deep, presumably to catch unsuspecting planktonic life. When caught in the torchlight they zip off at great speed." (Author)] Address: not stated

3782. Thakoor, S.; Chahl, J.; Srinivasan, M.V.; Young, L.; Werblin, F.; Hine, B.; Zornetzer, S. (2003): Bioinspired engineering of exploration systems for NASA and DoD. *Artificial Life* 8(4) (2002): 357-369. (in English). ["A new approach called bioinspired engineering of exploration systems (BEES) and its value for solving pressing NASA and DoD needs are described. Insects (for example honeybees and dragonflies) cope remarkably well with their world, despite possessing a brain containing less than 0.01% as many neurons as the human brain. Although most insects have immobile eyes with

fixed focus optics and lack stereo vision, they use a number of ingenious, computationally simple strategies for perceiving their world in three dimensions and navigating successfully within it. We are distilling selected insect-inspired strategies to obtain novel solutions for navigation, hazard avoidance, altitude hold, stable flight, terrain following, and gentle deployment of payload. Such functionality provides potential solutions for future autonomous robotic space and planetary explorers. A BEES approach to developing lightweight low-power autonomous flight systems should be useful for flight control of such biomorphic flyers for both NASA and DoD needs. Recent biological studies of mammalian retinas confirm that representations of multiple features of the visual world are systematically parsed and processed in parallel. Features are mapped to a stack of cellular strata within the retina. Each of these representations can be efficiently modeled in semiconductor cellular nonlinear network (CNN) chips. We describe recent breakthroughs in exploring the feasibility of the unique blending of insect strategies of navigation with mammalian visual search, pattern recognition, and image understanding into hybrid biomorphic flyers for future planetary and terrestrial applications. We describe a few future mission scenarios for Mars exploration, uniquely enabled by these newly developed biomorphic flyers." (2003): The lure effect, tadpole tail shape, and the target of dragonfly strikes. *Journal of Herpetology* 37(2): 420-423. (in English). ["Tadpoles of many species develop enlarged tail fins in the presence of insect predators, but the function of this response is not known. Because large tails do not improve swimming performance, we tested the hypothesis that the tail attracts predator strikes away from the more vulnerable head and body region. We first confirmed the assumption that attacks to the tail are less dangerous: Living tadpoles escaped from dragonfly larvae only 10% of the time when the strike landed on the head and body but 29.4% of the time when struck on the tail. We then constructed model tadpoles having four tail shapes: normal, predator-induced, and 50% shallower and 50% deeper than normal. The models were presented to dragonflies and the location at which the insect's labium struck the model was noted. Models having the predator-induced tail sustained 16% fewer strikes to the head and body than did models with the non-induced tail, lending credibility to the hypothesis that the tail acts as a lure. Models with an unnaturally large tail were attacked more often on the body than was the predator-induced model, which may create stabilizing selection on tail shape." ["The paper reports a new species of the genus Sinocnemis Wilson et Zhou. Type specimens are preserved in the Henan Academy of Science, China. Sinocnemis henanese, sp. nov. Measurements (mm): Abd. apprxapp. ♂ 35 mm apprx38 mm, ♀ 32 mm apprx34 mm. Hind-wing ♂ 28 mm apprx32 mm, ♀ 30 mm apprx32.5 mm. This species is similar to Sinocnemis yangbingi Wilson et Zhou, but differs from the latter as follows: 1) Pronotum of ♂ and ♀ with two yellowish round spots; 2) no small stripe at the upper posterior corner of the mesepimeron of synthoax; 3) lateral margin of abdominal segments 3 apprx4 with long yellowish stripe; 4) terminal margin of distal segment of penis with a apophysis. Holotype: ♂, Mt. Baiyun, Song County, Henan Province, 06-VIII-

1996, coll. WANG Zhi-guo. Paratypes: 1 ♀ Jiyuan County, Henan Province, 17-V-1987, coll. XI-AO Jian-guang; 2 ♂♂, 1 ♀ Lushan County, Henan Province, 22-VI-1990, coll. WANG Zhi-guo." (Author)] Address: Wang Zhi-guo, Henan Academy of Science, Zhengzhou, Henan, 450002 China

3790. Watson, E.J.; Carlton, C.E. (2003): Spring succession of necrophilous insects on wildlife carcasses in Louisiana. *Journal of Medical Entomology* 40(3): 338-347. (in English). ["Seven fresh animal carcasses were monitored throughout decomposition in a mixed flat-wood forest in East Baton Rouge Parish, LA from 1 April to 1 July 1999. Succession patterns of necrophilous insects were documented for the following: one Louisiana black bear (threatened species), two white-tailed deer, two alligators, and two swine as the experimental reference. Our results suggest variation in the species composition of necrophilous insects among animal carcass types. A total of 93 arthropod species, from 46 families and three classes, were manually collected from the seven carcasses. Only 19 insect species were collected on all four animal types and were represented by eight families: Coleoptera: Histeridae, Nitidulidae, Silphidae, Staphylinidae; Diptera: Calliphoridae, Muscidae, Piophilidae, Sepsidae. Eleven of the 46 families were not collected at either alligator site but were observed at bear, deer, and swine carrion: Coleoptera: Cleridae, Dermestidae, Geotrupidae, Scarabaeidae; Diptera: Micropezidae, Sarcophagidae, Syrphidae; Hymenoptera: Apidae; Lepidoptera: Nymphalidae; and Odonata: Libellulidae. Residency and succession patterns of necrophilous insects are presented for each animal type with particular emphasis on selected fly (Calliphoridae, Muscidae, Piophilidae, Stratiomyidae) and beetle species (Cleridae, Dermestidae, Histeridae, Nitidulidae, Silphidae, Staphylinidae)." 3795. Willigalla, C.; Menke, M.; Kronshage, A. (2003): Naturschutzbedeutung von Regenrückhaltebecken. Dargestellt am Beispiel der Libellen in Münster/Westfalen. *Naturschutz und Landschaftsplanung* 35(3): 83-89. (in German, with English summary). [Nordrhein-Westfalen, Germany; "In the city of Münster rain storage ponds have been constructed since 1980 to temporarily store peak flow discharge and large amounts of surface effluents. A dragonfly inventory of all rain storage ponds identified 27 species (61 % of a total of 44 species occurring in the city area of Münster), with 22 classified as (potentially) permanent settlers and five species as guests. Beside species frequently occurring at all types of water habitats of the city area a number of specialised species could be found. The earlier comprise *Cercion lindenii*, *Erythromma najas*, *Ischnura pumilio*, and *Aeshna grandis*, more specialised species are *Lestes dryas*, *Somatochlora metallica*, and *Orthetrum brunneum*. The colonisation depends on the one hand on light conditions and vegetation structure of the ponds, on the other side on the spatial relationship to

other important dragonfly biotopes in Münster. The study shows that rain storage ponds in urban areas significantly contribute to the protection of mainly ubiquitous species but also support some more specialised species, at least as 'side-habitats' as referred to in the concept of metapopulations. Finally, the study proposes management and development measures for the establishment of rain storage ponds." 3798. Wong, A.; Smith, M. L.; Forbes, M. R. (2003): Differentiation between subpopulations of a polychromatic damselfly with respect to morph frequencies, but not neutral genetic markers. *Molecular Ecology* 12(12): 3505-3513. (in English). [*Nehalennia irene* "has two distinct female colour morphs. Individuals of one morph have male-like colouration and pattern (androchromes), whereas gynochromes are different from males and androchromes in these respects. In several damselflies, such female-limited polychromatism is attributable to a single genetic locus. We developed six polymorphic genetic markers, which were codominant, to test for genetic differentiation in *N. irene*, collected from two sites located 8 km from one another in eastern Ontario, Canada. Based on three censuses spanning a 10 year period (1992-2001), morph ratios differed consistently and significantly between these two sites. However, subpopulations at these sites were not genetically differentiated with respect to the putatively neutral markers. Our results suggest that site differences in morph ratios of female *N. irene* cannot be explained by genetic drift, but are consistent with spatially variable selection operating on different morphs, perhaps mediated by male

density. Alternatively, morph type may be a plastic trait and cues for induction may differ between sites." (Authors)] Address: Wong, A., Dept of Molecular Biology and Genetics, Biotechnology Building, Cornell University, Ithaca, NY 14853 USA. E-mail: aw246(@)cornell.edu

(2003): Distribution of PER protein, pigment-dispersing hormone, prothoracicotropic hormone, and eclosion hormone in the cephalic nervous system of insects. *Journal of Biological Rhythms* 18(2): 106-122. (in English). ["Investigations performed on adult insects revealed that putative components of the central pacemaker, the protein Period (PER) and the pigment-dispersing hormone (PDH), are immunocytochemically detectable in discrete sets of brain neurons throughout the class of Insecta, represented by a bristletail, mayfly, damselfly, 2 locust species, stonefly, 2 bug species, goldsmith beetle, caddisfly, honeybee, and 2 blowfly species. The PER-positive cells are localized in the frontal protocerebrum and in most species also in the optic lobes, which are their only location in damselfly and goldsmith beetle. Additional PER-positive cells occur in a few species either in the deuto- and tritocerebrum or in the suboesophageal ganglion. The PER staining was always confined to the cytoplasm. The PDH immunoreactivity consistently occurs in a cluster of perikarya located fronto-ventrally at the proximal edge of the medulla. The mayfly and both locust species possess additional PDH neurons in 2 posterior cell clusters at the proximal edge of the medulla, and mayfly, waterstrider, and 1 of the blowfly species in the central brain. PDH-positive fibers form a fanlike arrangement over the frontal side of the medulla. Two or just 1 bundle of PDH-positive fibers run from the optic lobe to the protocerebrum, with collaterals passing over to the contralateral optic lobe. Antisera to the prothoracicotropic (PTTH) and the eclosion (EH) hormones, which in some insects regulate the molting and ecdysis rhythms, respectively, typically react with a few neurons in the frontal protocerebrum. However, the PTTH-positive neurons of the mayfly and the damselfly and the EH-positive neurons of the caddisfly are located in the suboesophageal ganglion. No PTTH-like antigen was detected in locusts, and no EH-like antigens were detected in the damselfly, stonefly, locusts, and the honeybee. There are no signs of colocalization of the PER-, PDH-, PTTH-, and EH-like antigens in identical neurons." 3803. Zawal, A.; Janicki, D. (2003): Pasożytowanie larw wodopójek z rodzaju *Arrenurus* na imagines wazek pochodz'cych z okolic Barlinka. In: *Zoologia na progu XXI wieku. Streszczenia referatów i plakatów ogólnopolskiej konferencji.* - [Zoologie an der Schwelle des XXI Jahrhunderts. Zusammenfassungen der Vorträge und Poster der allpolnischen Tagung]. Polskie Towarzystwo Zoologiczne, Uniwersytet Miko³aja Kopernika w Toruniu, Toruń: 257-258. (in Polish). [*Arrenurus* water mites as parasites of imagines of different odonate species in the environ of Barlinek, Poland - 557 odonate specimens from 24 species were collected. A total of 2218 specimens of water mites are reported. The infection rate is outlined for the following species as follows: *Enallagma cyathigerum* (56,5%), *Coenagrion puella* (53,6%), *Ischnura elegans* (46,9), and *Coenagrion pulchellum* (41,9%). Only two anisopteran species were infected: *ordulia aenea* (14,3%) and *Sympetrum sanguineum* (4%). In most cases, females were parasitised more intensively than males. Seperated according the odonate topography, the mites preferred the following regions: Metathorax: 910, mesothorax: 464, abdominal segment 1: 371, abdominal segment 2: 200, abdominal segment 3: 63.] Address: Zawal, A., Uniwersytet Szczecinski, Wydział Nauk Przyrodniczych, Katedra Zoologii Bezkręgowców i Limnologii, ul. - 3804.** Jansen, W.; Steiner, R.; Peissner, T.; Hövel, S.; König, A.; Rahmann, H. (1997): 4.3 Libellen. In: Böcker, R. (Ed.): Erfolgskontrolle im Naturschutz am Beispiel des Moorkomplexes Wurzacher Ried. Agrarforschung in Baden-Württemberg 28: 142-172. (in German). [Bad Wurzach (9.53E 47.54N), Baden-Württemberg, Germany; this fen bog is one of the most important in the middle range mountain region of Germany. Many habitat management measures have been realised to improve habitat quality. In spite of the importance of this fen bog, quite few older data on Odonata are available. Contrarily, in the 1990th, data on Odonata were extensively collected. To assess the measures and to make a prognosis on population development in the near future, key stone species (e.g. *Aeshna subarctica elisabethae*, *Somatochlora arctica*, *Lestes virens*, *Nehalennia speciosa*, *Coenagrion hastulatum*, *Leucorrhinia pectoralis*, *L. dubia*, *L. rubicunda*) were monitored. Without open water surfaces, many typical species will disappear. Conflicts between the management task to restore an undisturbed high bog (with a close sphagnum-vegetation and few typical odonate species) and a high bog with (small) peat ponds exploited by hand (high odonate diversity) are discussed. It is proposed to create suitable water bodies by peat cutting realising the so-called 'rotation model' of H. Wildermuth.] Address: Rahmann, H., Inst. Zool., Univ. (in German with English summary). ["Conspicuous, bright colorations of insect compound eyes may be caused by two different mechanisms resulting in different functions: 1) A thin layer of bright, light scattering pigment inside the pigment cells bordering cornea and crystalline cones may determine the eye's outer appearance when seen through the transparent dioptric apparatus. The insect's vision is not influenced by this phenomenon (STAVENOA 1979). The cornea transmits light equally well for all wavelengths involved in vision. As examples *Ischnura elegans* (Odonata: Coenagrionidae) and *Lathyrrophthalmis aeneus* (Diptera: Syrphidae) are presented. 2) Interference filters in the cornea cause colorful, metallic reflections. Transmission measurements of single cornea lenses revealed that the interference filters act as color filters by reducing transmission of light in a small limited waveband. These filters influence vision, because they change the spectral composition of visual stimuli. Results of transmission measurements of cornea lenses of *Heptatoma pellucens* FABRICIUS (Diptera: Tabanidae) and *Poecilobothris nobilitatus* Linné (Diptera: Dolichopodidae) are given." Biological Survey of Canada (Terrestrial Arthropods)*, Ottawa. 1034 pp: 911-962. (in English). [Verbatim: [...] Odonata. Despite the thickly sclerotized character of certain parts of adult damselflies and dragonflies, the only fossils identified to date are the distinctive mandibles. The odonate mandibles are so distinct that there may be a potential for identification at least to the family level. Their occurrence in Yukon samples is rare mainly because many of the samples studied to date represent treeline or tundra environments, not the types of habitat in which dragonflies and damselflies are abundant. One of the samples from Rock River (Table 2) contains a fragment of the genital apparatus of an odonate, but such fossils are very rare. Odonate larvae possess sclerotized and very distinctive mouthparts which one might expect to preserve as fossils, but to date none has been recovered from Yukon samples. 3812. Rückriem, C.; Roscher, S. (1999): Empfehlungen zur Umsetzung der Berichtspflicht gemäß Artikel 17 der Fauna-Flora-Habitat-Richtlinie. Angewandte Landschaftsökologie 22: 456 pp. (in German with English and French summary). ["Recommendations on the implementation of the reporting obligations according to article 17 of the Habitats Directive of the EU. "This work consists of two major parts: The first part deals with the requests on the implementations of the reporting obligations as they can be derived from the Habitats Directive. The different levels involved are mentioned, as the Natura 2000 Sites, the Member States and the European Union. For anyone interested in the Habitats Directive and its implementation basic information is provided. In the second part (chapter 3-6) detailed proposals for the implementation of the reporting obligations are made. This part is addressed mainly to experts responsible for the implementation and, at a later stage, for the performing of the reports. The major aim of the proposals made is to provide a basis for discussion and to encourage future work on this topic. Further expert discussions and amendments are needed in order to establish an appropriate, standardized, and cost-effective procedure for the reports. Based on a proposal for the reporting procedure, standards for parameters, methods and criteria for the evaluation of the conservation status of habitat types are explained. Detailed suggestions for the reporting procedure as it could be performed at a particular NATURA 2000 Site are made for 17 habitat types. For the implementation and the use of geographic information systems (GIS) the reporting procedure suggestions are made which are based on the

experiences gained in the project. The suggestions are explicitly designed to minimize the reporting efforts as far as possible." (Authors) On pages 378-380 the standards referring to the Odonata are outlined.] Address: Rückriem, C., c/o Bundesamt für Naturschutz, Konstantinstr. 110, D-53179 Bonn, Germany

[Germany; baseline investigations for preparing a management plan for an acid, nutrient-poor water body included Odonata. In 1996 and 1997, 17 odonate species were recorded. Additional records from 1985, and data base records for the same locality, increase the list of the odonata to 24 species. The records of *Lestes barbarus*, *Erythromma viridulum*, *Leucorrhinia dubia*, *Sympetrum sanguineum*, and *S. flaveolum* are briefly discussed.] Address: Glandt, D., Biologisches Institut Metelen e.V., Samberg 65, D-48629 Metelen, Germany

3819. Jeyaprakash, A.; Hoy, M.A. (2000): Long PCR improves *Wolbachia* DNA amplification: wsp sequences found in 76% of sixty-three arthropod species. Insect Mol Biol 9(4): 393-406. (in English). ["Bacteria belonging to the genus *Wolbachia* are associated with a variety of reproductive anomalies in arthropods. Allele-specific polymerase chain reaction (= Standard PCR) routinely has been used to amplify *Wolbachia* DNA from arthropods. While testing the two-spotted spider mite *Tetranychus urticae* and other arthropods known to be infected with *Wolbachia*, Standard PCR frequently produced false negatives, perhaps because the DNA from the arthropod host interfered with amplification by Taq DNA polymerase. Long PCR, which uses two enzymes (Taq and Pwo), consistently amplified *Wolbachia* DNA and a sensitivity analysis indicated that Long PCR was approximately six orders of magnitude more sensitive than Standard PCR in amplifying plasmid DNA spiked into insect genomic DNA. A survey indicated that 76% of sixty-two arthropod species and two subspecies in thirteen orders tested positive for the *Wolbachia* wsp sequence by Long PCR, which is considerably higher than the rate of 16.9% obtained previously for the *ftsZ* sequence using Standard PCR (Werren, J.H., Windsor, D. and Gao, L. (1995a) Proc R Soc Lond B 262: 197-204). A subsample of Long PCR products from fourteen arthropod species and two subspecies were sequenced, both directly and after cloning. Two A- and eleven B-*Wolbachia* strains were detected and their wsp sequences displayed a maximum of 23.7% sequence divergence at this locus. Two new groups (named Fus and Ten) were identified in addition to nineteen reported earlier (Zhou, W, Rousset, F. and O'Neill, S.L. (1998) Proc R Soc Lond B 265: 1-7; van Meer, M.M.M., Witteveldt, J. and Stouthamer, R. (1999) Insect Mol Biol 8: 399-408), because they displayed more than 2.5% sequence divergence from other *Wolbachia* wsp se-

quences. PCR products from seventeen of twenty-nine (59%) arthropod species analysed could not be sequenced directly due to apparent infection by multiple *Wolbachia* strains. The wsp sequences cloned from two such species (*Plutella xylostella* and *Trichoplusia ni*) indicated both A- and B-*Wolbachia* were present in a single individual. Hence, superinfection also may be more widespread than the 1.2% incidence previously estimated." (Authors) *Perithemis tenera* was positively tested for *Wolbachia* super-group B.] Address: Jeyaprakash, A., Department of Entomology and Nematology, PO Box 110620, University of Florida, Gainesville, FL 32611, USA. 3828. Cordero Rivera, A.; Andrés, J.A. (2001): Estimating female morph frequencies and male mate preferences of polychromatic damselflies: a cautionary note. Animal behaviour 61: F1-F6. (in English). ["In all populations studied, the frequency of androchromes changed greatly between days, but only in the *I. elegans* population was a significant correlation found between androchrome frequency and date (Kendall's rank correlation coefficient: $T = -0.33$, $N=25$, $P<0.05$). The coefficient of variation of androchrome frequency was 18% for *I. elegans*, 26-73% for *I. graellsii*, 110% for *I. pumilio* and 61-76% for *C. tenellum*. Sample sizes of fewer than 100 females will rarely be a good estimate of the true population frequency. It is only above this that the frequency tends to become independent of sample size. Male preference for female colour morphs has been studied in 12 *Coenagrionidae* and one *Calopterygidae* species (listed in Table 1). Some studies have presented live tethered females to males and recorded whether males responded in a sexual or nonsexual way to the model. Other studies used immobile models (either dead or alive, paired or not) glued or pinned to the tip of a stem. Finally, a few followed male-female interactions in free-living specimens (Sirot 1999), or used small cages where males were allowed to choose between two females (Van Gossum et al. 1999). We have calculated the percentage of males that showed sexual

interest to androchrome models, excluding males that did not respond. This measure of male interest in androchromes does not correlate with the frequency of this morph in the population (all experiments: Spearman correlation: $r_s = -0.14$, $N=19$, $P=0.566$; experiments with live models (tethered, glued or pinned) presented one at a time: $r_s = -0.46$, $N=10$, $P=0.184$; all experiments with dead models: $r_s = 0.14$, $N=7$, $P=0.758$)."] (Authors)] Address: Cordero Rivera, A., Departamento de Ecología e Biología Animal, Universidade de Vigo, E.U.E.T. 3830. Fartmann, T.; Gunnemann, H.; Salm, P.; Schröder, E. (2001): Berichtspflichten in Natura-2000-Gebieten Empfehlungen zur Erfassung der Arten des Anhangs II und Charakterisierung der Lebensraumtypen des Anhangs I der FFH-Richtlinie. Angewandte Landschaftsökologie 42: 725 pp, Appendix. (in German with English summary). ["Intensive studies of the natural habitat types listed in Annex I and the populations of the species listed in Annex II of the Habitats Directive were conducted in eight study areas of the continental biogeographic region of Germany as part of two research and development projects of the Federal Agency for Nature Conservation. These studies had two primary goals: first of all, to assess methods for the standardized registration of the species listed in Annex II as required by the reporting obligations according to article 17 of the Habitats Directive and to recommend species-specific methods. Secondly, to subject habitat types of Annex I to a more exhaustive, and particularly ecological characterization. Methods are suggested for the evaluation of the conservation status of the 96 plant and animal species listed in Annex II that presently occur in Germany, as well as six further species listed in Annexes IV and V as required by the reporting obligations. These methods are based in part on our own studies. For each species the relevant ecological characteristics required for its registration, the habitat requirements, and the factors of its endangerment are briefly described. In a second step, methods judged to be appropriate are presented and discussed. In the final recommendation, the selected methods are described in more detail with regard to their practical application, the data acquisition periods and their frequency, as well as the time requirements. The recommended methods should be able to produce reproducible results, to allow conclusions about the development of populations in the protected sites and have a neutral cost-benefit relationship. In the presentation and the discussion, the methods are differentiated into those for recording species or populations and those for recording their habitats. All suggestions pertain to the surveillance of the species' conservation status in Natura 2000 sites. The ecological characterization of the FFH habitat types was primarily made by floristic surveys that encompassed a total of 44 different types. [...]"] (Authors) The Odonata are treated in chapter 4.3.6 on pages 323-355. *Aeshna viridis* (Petra Salm), *Coenagrion mercuriale* (Wolfgang Röske), *Leucorrhinia albifrons*, *L. caudalis*, *L. pectoralis* (Rüdiger Mauersberger), *Stylurus flavipes*, *Ophiogom-*

phus cecilia (P. Salm, Ole Müller), and *Oxygastra curtisii* (Klaus-Guido Leipelt).] Address: Schröder, E., c/o Bundesamt für Naturschutz, Mallwitzstr. 1-3, D-53170 Bonn, Germany

3831. Galdean, N.; Callisto, M.; Barbosa, F.A. (2001): Biodiversity assessment of benthic macroinvertebrates in altitudinal lotic ecosystems of Serra do Cipó (MG, Brazil). *Revista brasileira de biologia* 61(2): 239-248. (in English, with Portuguese summary). ["Five lotic systems of Serra do Cipó, south-east Brazil, were investigated in order to assess the existing diversity of benthic macroinvertebrates, habitats-microhabitats, and the available trophic resources. For each river the communities of benthic macroinvertebrates and the composition of some taxonomic groups (Plecoptera, Ephemeroptera, Trichoptera and Diptera Chironomidae) were analysed: the community with Bivalvia, Sphaeriidae, Oligochaeta and Ephemeroptera-Baetidae (being supposed a closed relation Bivalvia-Oligochaeta based on the process of bioturbation and enrichment of sediment in organic matter) in Tanque River; the macrofauna associated to aquatic macrophytes from rivers Peixe and Preto do I-també reflecting the reaction of the ecosystems versus the quantities of nutrients which originate from the farmlands; the lithoreophilic communities of Cipó River; the community depending on deposits of leaves and filamentous algae in Congonhas Stream; the very rich community of the moss clumps in the Indaiá Stream. A proposal for biological zonation of Cipó River and some comments about the importance of the analysed benthic macroinvertebrates in the biological production of the aquatic communities were done." (Authors) Odonata are mentioned on the order level only.] Address: Callisto, M., Laboratório de Limnologia/Ecologia de Bentos, Departamento de Biologia Geral, Universidade Federal de Minas Gerais, ICB, C.P. 486, CEP 30161-970, Belo Horizonte, MG, Brazil. 3832. Kesel, A.B. (2001): The ultralight aerofoils of insects - an evolutionary masterpiece. *Zoology - Analysis of Complex Systems* 103(3-4): 222-229. (in English). ["The development of wings can be regarded as the key innovation in the course of insect evolution. They make locomotion in a three-dimensional space possible, a world wide spreading and the inhabitation of almost all biotopes. Due to their low mass and high stability, wings can be interpreted as ultralight aerofoils. To guarantee the enormous mechanical demands of flight, the material and its geometrical arrangement are of crucial importance. The wings are part of the cuticular exoskeleton of the insects. This cuticle is a helicoidal fibre reinforced material of crystalline biopolymers, embedded in a protein matrix. Apart from providing the necessary stability, the ingenious structure design induces excellent aerodynamic performance. The statics as well as the aerodynamic quality of the highly complex system wing are supported throughout all hierarchic levels by a series of fine structures." 3833. Lan, S.; Sun, M. (2001): Aerodynamic force and flow structures of two airfoils in flapping motions. *Acta Mechanica Sinica (English Series)* 17(4): 310-331. (in English). ["Aerodynamic force and flow structures of two airfoils in a tandem configuration in flapping motions axe studied, by solving the Navier-Stokes equations in

moving overset grids. Three typical phase differences between the fore- and aft- airfoil flapping cycles are considered. It is shown that: (1) in the case of no interaction (single airfoil), the time average of the vertical force coefficient over the downstroke is 2.74, which is about 3 times as large as the maximum steady- state lift coefficient of a dragonfly wing; the time average of the horizontal force coefficient is 1.97, which is also large. The reasons for the large force coefficients are the acceleration at the beginning of a stroke, the delayed stall and the "pitching-up" motion near the end of the stroke. (2) In the cases of two-airfoils, the time-variations of the force and moment coefficients on each airfoil are broadly similar to that of the single airfoil in that the vertical force is mainly produced in downstroke and the horizontal force in upstroke, but very large differences exist due to the interaction. (3) For in-phase stroking, the major differences caused by the interaction are that the vertical force on FA in downstroke is increased and the horizontal force on FA in upstroke decreased. As a result, the magnitude of the resultant force is almost unchanged but it inclines less forward. (4) For counter stroking, the major differences are that the vertical force on AA in downstroke and the horizontal force on FA in upstroke are decreased. As a result, the magnitude of the resultant force is decreased by about 20 percent but its direction is almost unchanged. (5) For 90 degrees - phase-difference stroking, the major differences axe that the vertical force on AA in downstroke and the horizontal force on FA in upstroke axe decreased greatly and the horizontal force on AA in upstroke increased. As a result, the magnitude of the resultant force is decreased by about 28% and it inclines more forward. (6) Among the three cases of phase angles, inphase flapping produces the largest vertical force (also the largest resultant force); the 90 degrees -phase-difference flapping results in the largest horizontal force, but the smallest resultant force." 3835. Mizera, F.; Bernath, B.; Kriska, G.; Horvath, G. (2001): Stereo videopolarimetry: Measuring and visualizing polarization patterns in three dimensions. *Journal of Imaging Science and Technol.* 45(4): 393-399. (in English). ["Because the human eye is practically blind to the polarization of light, biologists dealing with polarization vision of animals, or engineers designing robots using polarization- sensitive computer vision to enhance contrast in the optical environment need a technique to image the spatial distribution of polarized light in the visual environment. Recently, different kinds of imaging polarimetry were developed to measure the polarization patterns of objects and natural scenes in a single, two-dimensional, wide field of view. As a further development of this technique, we report here on the realization

of the addition of depth to scenes imaging the distribution of polarized light: One kind of stereo videopolarimetry was designed to measure and visualize in three dimensions the polarization patterns in nature and to mimic the ability of animal-eyes to receive visual information from a binocular field of view. We demonstrate the power of stereo videopolarimetry on an applied problem representing (in parallel view stereo format) a three-dimensional object, a car with a shiny bodywork and also having strong reflection polarization. The technical difficulties and hitches of stereo videopolarimetry as well as the importance of the distance of observation, the role of the angle of view, the influence of the color of the object, and the possibility to state differences between metallized and non-metallized paints are discussed." 3838. Schmidt, B.R.; Amezcua, A. (2001): Predator-induced behavioural responses: Tadpoles of the neotropical frog *Phyllomedusa tarsius* do not respond to all predators. Herpetological journal 11(1): 9-15. (in English). ["Many species show behavioural responses to predators that reduce predation mortality but are assumed to be costly. We tested whether an induced behavioural response is predator-specific and whether the strength is related to the risk of being killed by a predator. We used tadpoles of the neotropical frog *Phyllomedusa tarsius* as prey, and larvae of an aeshnid dragonfly and belostomatid bugs as predators. Belostomatids killed twice as many tadpoles within 24 hours as aeshnids did. Tadpoles reduced activity in the presence of aeshnids by 30% but did not respond at all to the more dangerous belostomatids. Tadpoles did not show spatial avoidance of predators. We favour the explanation that tadpoles of *P. tarsius* did not respond to belostomatids because belostomatids are encountered too rarely for evolution to favour an induced response to belostomatids." 3843. Wilson, K.D.P. (2001): *Orthetrum poecilops* Ris - A marine dragonfly of conservation priority. *Porcupine* 22: 5-9. (in English). [Porcupine is the Newsletter of the Dept of Ecol. and Biodiv. of the Univ. of Hong Kong. It contains a highly interesting compilation on the ecology, biology, distribution, synonymie, and identification of *O. poecilops*. The species is one of the very few odonate species which develops in brackish water. It is concluded that none of the few localities of the species is represented in the network of special protected areas in Hong Kong. The conservation of this "global rarity" should be considered a high priority.] Address: Wilson, K.D.P., Flat 20, 6 Mansfield Road, The Peak, Hong Kong, China. E-mail: wilsonkd@netvigator.com

3844. Worthen, W.B.; Haney, D.C.; Cuddy, C.C.; Turgeon, V.L.; Andersen, C.B. (2001): The effect of an industrial spill on the macrofauna of a South Carolina stream: Physiological to community-level responses. *Journal of Freshwater Ecology* 16(3): 467-477. (in English). ["In 1985, a waste retention pond ruptured at a galvanizing facility and spilled 75,700 liters of HCl and other contaminants into the groundwater above the Upper Enoree River in South Carolina, USA. In 1999, we examined the residual effects of this spill by surveying the water chemistry and biota in the main channel of the Upper Enoree River and uncontaminated tributaries. We also transplanted yellowfin shiners (*Notropis lutipinnis*) to channel and tributary sites and monitoring

their survivorship and the histological condition of their gills. The two upstream sites were significantly different in chemical composition from downstream sites and control tributaries.[...] The abundance and diversity of salamanders, fish, and macroinvertebrates correlated with these changes in water chemistry. Yellowfin shiners transplanted to the headwater site died within 24 hours, and fish in channel sites had significantly higher mortality than fish transplanted to tributary sites. At the tissue level, the size and density of gill pavement cells were significantly lower in fish transplanted into the two headwater sites closest to the spill compared to other channel and tributary sites. Thus, this spill continues to exert a significant effect on the chemistry and biota of the Upper Enoree River. [...] On average, invertebrate communities in the channel were similar to invertebrate communities in the tributaries and in other streams in the county. The channel sites had significantly fewer crayfish than tributaries and other county sites, but most other means were comparable. A total of 1256 macroinvertebrates was collected in the Upper Enoree, representing eight orders. Odonates accounted for 49.8% of the total sample, with a disproportionate number of *Progomphus obscurus* ($n = 228$) and *Cordulegaster maculata* ($n = 222$). 3846. Bernard, R.; Buczyński, P.; Tończyk, G. (2002): Present state, threats and conservation of dragonflies (Odonata) in Poland. *Nature Conservation* 59 (2004) : 53-71. (in English). ["72 species of dragonflies have been recorded in Poland so far. The present state of knowledge of Odonata is generally moderate and unequal with reference to the particular regions. The main current topics in Polish Odonatological studies are briefly presented. The current picture of dragonfly fauna has been drawn, with special attention to the increased abundance and the broadened ranges of some Mediterranean and southeastern species (e.g. *Aeshna affinis*, *Orthetrum albistylum*), and to the falling numbers, the increasing scatter of localities and the narrowing ranges of some other species, mainly stenotopic (e.g. *Nehalennia speciosa*, *Coenagrion armatum*, *Coenagrion ornatum*). Threats and their mechanisms of affecting dragonflies are analysed in all the main water habitats in Poland. The species typical of small running waters and habitats connected with *Sphagnum* are the most endangered. It must be stressed, however, that generally the state of Polish dragonfly fauna is fairly good. The main forms of conservation of dragonflies, currently used or proposed for use in Poland, are analysed: passive (species and territorial protection, red list, umbrella species) and active (reintroduction, creating new waterbodies, interference in succession of wa-

terbody). The choice of species protected in Poland is partly inappropriate in comparison with the present situation of dragonfly fauna. The Polish Red List, comprising 16 species, is discussed in comparison with the red lists of other European countries. It is stressed that no species has become extinct in Poland. The proposed list of umbrella species for particular habitats is given. The Wildermuth's rotation model is suggested for the management of some habitats. All issues described in the article are presented synthetically and illustrated with the data and examples from Poland." (Authors)] Address: Bernard, R., Department of General Zoology, Adam Mickiewicz University, Fredry 10, PL-61-702 Poznań, Poland; E-mail: rbernard@main.amu.edu.pl

3847. Callisto, M.; Moreno, P.; Barbosa, F.A.R. (2002): Habitat diversity and benthic functional trophic groups at Serra do Cipó, southeast Brazil. *Revista Brasileira de Biologia* 61(2): 259-266. (in English with Portuguese summary). ["The assessment of the diversity of habitats and the characterisation of the functional trophic groups of benthic macroinvertebrate communities of some rivers of Serra do Cipó (MG) were the main objectives of this study. The available trophic resources and the types of substrata were characterised along with the structure and composition of their using functional trophic groups. Serra do Cipó is a watershed divisor of the São Francisco and Doce River basins, including a series of streams and rivers, of good water quality and well preserved ecological characteristics. Samples were collected in Cipó, Peixe and Preto do I-també rivers, besides the Indaiá and Capão da Mata streams at 26 sampling stations, during the rainy (February) and dry (October) seasons of 1998, using Kicking nets of 0.125 mm mesh size. The group of collectors (Baetidae, Leptophlebiidae and Leptohyphidae) was the most abundant, followed by collector-predators (Hydrophilidae, Ceratopogonidae, Chironomidae-Tany-podinae), and detritivorous-herbivores (Oligochaeta). The riparian vegetation, together with the aquatic macrophytes, are the substrata containing the highest richness of functional trophic groups and the higher habitat diversity. The results suggest that the use of functional trophic groups, together with habitat evaluation, are efficient tools in the evaluation of the diversity of benthic macroinvertebrates, particularly in altitudinal lotic ecosystems." (Authors) There are two passing references to Odonata.] Address: Callisto, M., Laboratório de Limnologia/Ecologia de Bentos, Departamento de Biologia Geral, Universidade Federal de Minas Gerais, ICB, C.P. 486, CEP 30161-970, Belo Horizonte, MG, Brazil. Untersuchungen zur Amphibien- und Libellenfauna, Bewertung aus tierökologischer Sicht sowie Pflege- und Entwicklungsmaßnahmen. *Jh. Ges. Naturk. Württemberg* 158: 223-236. (in German). [20 odonate species are reported from 10 so-called Hülben (local name for man-made small bodies of water in Ostalb, Baden-Württemberg, SW Germany). The ecological significance of the "Hülbe" odonate communities is analysed and

assessed.] Address: Detzel, P., Dreifelderstr. 31, D-70599 Stuttgart-Plieningen, Germany

3856. Ellenrieder, N. von; Costa, J.M. (2002): *Aeshna brasiliensis* sp. nov. (Odonata: Aeshnidae) from south and southeastern Brazil, with a redescription of its larva. *Neotrop. Ent.* 31(3): 369-376. (in English with Portuguese summary). [Holotype male: Rio Grande do Sul, Rio Tainha, alt. 900 m, 20-1-1959; allotype female: Rio de Janeiro, Itatiaia, Repressa do Planalto de Itatiaia; deposited in MNRJ. The new species resembles *A. variegata* and *A. peralta* in colour pattern of head and abdomen, but differs from them in thoracic colour pattern and in shape of cerci. The larva uniquely differs from all other known Brazilian congeners by lacking lateral spines on abdominal segment VI. The last larval stage of *A. brasiliensis* is (re-) described and diagnostic characters are illustrated. A map documents the present knowledge of distribution of the species in Brazil. *Aeshna peralta* Ris, 1918 differs morphological clearly from *A. variegata* Fabricius, 1775, and was recognised as a good species.] Address: Ellenrieder, Natalie von, Ent. Sect., Nat. Hist. Mus. Los Angeles Co., 900 Exposition Blvd, Los Angeles, CA 90007, USA

3857. Endersby, I.D. (2002): Australian Odonata in the international literature. *Austrolestes* 6: 1-3. (in English). [The paper compiles publications on taxonomy, ecology, and conservation of Australian Odonata in journals issued abroad Australia.] Address: Endersby, I., 56 Looker Rd, Montgomery, Victoria 3094, Australia. E-mail: endersby@werple.net.au

3858. Endersby, I.D. (2002): The dragonflies of Norfolk Island, with the first record of *Pantala flavescens* (F.) (Odonata: Libellulidae). *Ent. mon. Mag.* 138: 241-246. (in English). [The collecting history of Norfolk Island Odonata is traced since 1915. *Agriocnemis vitienensis* is considered a juvenile (not teneral) colour form of *A. exsudans*. This species and *Ischnura aurora*, *Aeshna brevistyla*, *Hemicordulia australiae*, and *Pantala flavescens* seem to be well established on the island. Observations of specimens of *Anax* sp. and *Diplacodes* sp. are to be confirmed on the species level. The distribution within the Pacific of the Odonata found on Norfolk Island is shown in a table. The colonisation of the island is discussed, and the probability of facultative immigrants or wind-blown individuals is considered extremely small.] Address: Endersby, I.D., 56 Looker Rd, Montmorency, Vie. 3094, AU

3859. Fouque, C.; Corda, E.; Debot, S.; Combaz, B.; Broyer, J. (2002): The reedbed inventory, a monitoring tool for a key habitat for aquatic avifauna. *Zeitschrift für Jagdwissenschaft* 48 (Supplement): 115-129. (in English). ["For several years, a decrease in the reedbed surface areas has not only been noted in certain sectors of France but also in Europe and throughout the world. The importance of reedbeds to the fauna is obvious, notably for all paludicolous fauna for which it is a nesting place. In this context, making an inventory of all reedbeds is in line with a patrimonial approach that eventually should lead to the creation of a reedbed observatory. Thanks to the creation of a national network of observers between 1998 and 2000, in one third of the national surface area an inventory could be made of all wet reedbeds covering more than 1 hectare. Almost 1000 wetlands were identified covering a surface area of more than 7000 hectares. Two typologies were defi-

ned based on the factors obtained by multiple correspondence analyses: the first one for the wetlands containing 6 classes and the second one for the reedbeds, containing 4 classes. Reedbed habitat quality was assessed in a sample of 125 sites through an evaluation of the number of species present in two groups of indicator species, Birds and odonates. The median values for a wetland successively amount to 2 species (0 to 15 species interval) and 7 species (0 to 18 species interval). The high values of these indicators are essentially linked to the reedbed's high water level for the first group, and to the reedbed's geographic situation for the second one. Other descriptive parameters of the reedbeds and wetlands harbouring indicator species also have an effect, although they are less important from a hierarchical point of view. Bird diversity is linked to a lot of these parameters, but dragonfly diversity is not. This is the first inventory of the state of the reedbeds in the East of France. When another one is made 10 years from now, it would allow us to make an overall appraisal of the quantitative and qualitative changes affecting all reedbed-covered areas on the basis of objective knowledge." 3860. Gorb, S.N.; Popov, V.L. (2002): Probabilistic fasteners with parabolic elements: biological system, artificial model and theoretical considerations. *Philos. Trans. R. Soc. Lond. Ser. A - Math. Phys. Eng. Sci.* 360 (1791): 211-225. (in English). ["Probabilistic fasteners are attachment devices composed of two surfaces covered with cuticular micro-outgrowths. Friction-based fasteners demonstrate high frictional forces when the surfaces come into contact. Attachment in this case is based on the use of the surface profile and mechanical properties of materials, and is fast, precise and reversible. The best-studied examples composed of parabolic elements are the wing-locking mechanism in beetles and the head arrester in dragonflies. This study combines experimental data of force measurements, obtained in an artificial model system, and theoretical considerations based on the simple model of behaviour of probabilistic fasteners with parabolic elements. Elements of the geometry in both cases correspond to the biological prototypes. Force measurements on the artificial system show that the attachment force is strongly dependent on the load force. At small loads, the increase of attachment is very slow, whereas rapid increase of attachment was detected at higher loads. At very high loads, a saturation of the attachment force was revealed. A simple explanation of the attachment principle is that with an increasing load elements of both surfaces slide into gaps of the corresponding part. This results in an increase of lateral loading forces acting on elements. High lateral forces lead to an increase of friction between single sliding elements. An analytical model which describes behaviour of the probabilistic fasteners with parabolic elements is proposed." (Authors)] Address: Gorb, S., Max-Planck-Institut für Entwicklungsbiologie, Spemannstr. 35, D-72076 Tübingen, Germany. E-mail: stas.gorb@tuebingen.mpg.de

3861. Ingermann, R.L.; Bencic, D.C.; Verrell, P. (2002): Methoxychlor alters the predator-prey relationship between dragonfly naiads and salamander larvae. *Bulletin of Environmental Contamination & Toxicology* 68(6): 771-778. (in English). ["The pesticide methoxychlor (MXC; 1,1'-[2,2,2-trichloroethylidene]bis[4-methoxy]-

benzene) has been widely used as a replacement for DDT due to its lower toxicity and shorter half-life. In Canadian rivers, MXC has been applied to wetlands to control fly and mosquito larvae, particularly in the spring and summer, with target concentrations of about 0.9 μM (0.31 mg/L). Inadvertent exposure of non-target organisms with such applications cannot be avoided and pesticides may have a variety of sublethal, but nonetheless highly deleterious, effects on amphibians. In addition, pesticides may influence predator-avoidance behaviour. Verrell (2000) has shown that exposure of *Ambystoma macrodactylum* - salamander eggs to MXC concentrations as low as 0.03 μM leads to increased predation when larvae are combined with dragonfly naiads. We lack predator-prey studies in which both predator and prey are exposed to the pesticide. Deleterious effects of MXC on the feeding and perching of dragonfly naiads ($n=109$ specimens of *Aeshna* sp. and one of *Anax* sp.) "were not apparent with transient exposures to concentrations below about 0.4 μM MXC, while the startle response of *A. macrodactylum* larvae was severely compromised by transient exposures to at least 0.1 μM MXC. This suggests that naiads should be particularly effective predators of *A. macrodactylum* larvae when both are exposed to MXC concentrations between about 0.1 and 0.4 μM . Indeed, with a transient exposure of both dragonfly naiads and *A. macrodactylum* larvae to 0.32 μM MXC, the amphibian larvae were at increased risk of predation. Furthermore, over the range of 0.01 to 0.32 μM MXC, there was a linear relationship between the logarithm of MXC concentration and increased risk of larval predation by naiads. This relationship did not hold above 0.32 μM MXC perhaps due to an MXC-induced inhibition of naiad feeding. The results of these studies indicate that relatively low concentrations of pesticides such as MXC can influence predator-prey relationships and can have significant deleterious effects on amphibian larvae beyond any direct lethal effects. Whether larvae die from direct chemical exposure or from an inability to negotiate challenges present within their local environment, such as an impaired ability to avoid predation, is inconsequential relative to the stability and/or persistence of an amphibian population. Our data underscore the importance of testing for indirect, sublethal effects of xenobiotic exposure on both individuals and populations. Analyses of the effects of xenobiotics on predator-prey interactions are prime targets for further investigation." [The paper compiles the present knowledge on the odonate fauna of the biosphere reserve in the northern Vosges, France, and outlines a brief history of odonatological sur-

veys in the region. Some species of species interest (boggy and running waters) are briefly discussed and the distribution of *Ophiogomphus cecilia* is mapped.] Address: Jacquemin, G., Biologie des Insectes, Université H. Poincaré, Nancy 1, BP 239, F-54506 Vandœuvre-lès-Nancy, France

3864. Jakab, T.; Muller, Z.; Devai, G.; Tothmeresz, B. (2002): Dragonfly assemblages of a shallow lake type Reservoir (Tisza-to, Hungary) and its surroundings. Acta Zool. Acad. Scient. Hungaricae 48(3): 161-171. (in English). ["The dragonfly fauna of the typical water bodies of the Reservoir Tisza-to was characterised based on a two-year study. We collected 728 imagoes, 384 larvae and 194 exuviae during the study, and there were 101 observations of imagos. We confirmed the presence of 39 species (13 Zygoptera and 26 Anisoptera). We distinguished 5 types of water bodies inside and around the Reservoir Tisza-to: leaking canals, a new inundated area of the reservoir, native water bodies inside the reservoir, in- and outflows, and River Tisza inside the reservoir. Both traditional diversity statistics and scalable diversity characterisation suggested that the most species-rich were the native water bodies, with a species-pool of 34 species; there were 30 species in the in- and outflows, while the leaking canals and the reservoir were moderately species-rich with 25 species each. The River Tisza was relatively species-poor compared to the other water bodies (12 species). Cluster analysis of the species composition revealed that the fauna of the River Tisza is clearly separated from the other water bodies. The fauna of the new inundated area, the native water bodies, and the in- and outflows were similar; these water bodies had direct connection to the reservoir. The fauna of the leaking canals was slightly different from them." (Authors)] Address: Jakab, T. Dept of Ecology and Hydrobiology, Debrecen University, P.O. Box 71, Debrecen, H-4010, Hungary. 3871. Mayhew, P.J. (2002): Shifts in hexapod diversification and what Haldane could have said. *Proc. R. Soc. Lond. B* 269: 969-974. (in English). ["Data on species richness and taxon age are assembled for the extant hexapod orders (insects and their six-legged relatives, includes Odonata). Coupled with estimates of phylogenetic relatedness, and simple statistical null models, these data are used to locate where, on the hexapod tree, significant changes in the rate of cladogenesis (speciation-minus-extinction rate) have occurred. Significant differences are found between many successive pairs of sister taxa near the base of the hexapod tree, all of which are attributable to a shift in diversification rate after the origin of the Neoptera (insects with wing flexion) and before the origin of the Holometabola (insects with complete metamorphosis). No other shifts are identifiable amongst supraordinal taxa. Whilst the Coleoptera have probably diversified faster than either of their putative sister lineages, they do not stand out relative to other closely related clades. These results suggest that any Creator had a fondness for a much more inclusive clade than the Coleoptera, definitely as large as the Eumetabola (Holometabola plus bugs and their relatives), and possibly as large as the entire Neoptera. Simultaneous, hence probable causative events are discussed, of which the origin of wing flexion has been the focus of much attention." - 3881.** Payne, J.C.; Dunley, J.E. (2002): Use of an elemental marker, rubidium, to study dispersal of aquatic insects. *Journal of the North American Benthological Society* 21(4): 715-727. (in English). ["We describe the first use of the element rubidium (Rb) to mark aquatic insects for the study of dispersal. It has been difficult to pursue research that integrates juvenile and adult life stages of aquatic insects. Most species of aquatic insects suffer high mortality during the larval phase; furthermore, larvae shed their entire exoskeletons as they emerge. Adults disperse by flying soon after emergence when they may still be fragile and difficult to handle. We demonstrate that it is possible in both controlled and natural settings to batch-mark very large numbers of aquatic dragonfly (Odonata) larvae by adding Rb as RbCl to the water in which they live. We found that the in-body concentration of Rb in odonate larvae rose to several hundred times the concentration of Rb in the water, and the high concentrations persisted in adults. Less than 1 part per million (by mass) of Rb in water was sufficient to mark odonate larvae. Rb is often used in research on dispersal of terrestrial insects, particularly crop pests, because it is relatively inexpensive and nontoxic at low concentrations. Rb is known to cause developmental problems in insects (probably through competitive binding with K) at much higher concentrations than we used, but we did not detect any evidence of toxicity at the levels used. The cost of Rb and of specimen analysis by atomic absorption spectrophotometry is moderate, compared to other marking techniques. We believe the method is an improvement over other marking techniques, and will facilitate the study of dispersal of aquatic insects, in cases where dispersing adults can be recaptured." - 3886.** Reimchen, T.E.; Nosil, P. (2002): Temporal variation in divergent selection on spine number in threespine stickleback. *Evolution* 56(12): 2472-2483. (in English). ["Short-term temporal cycles in ecological pressures, such as shifts in predation regime, are widespread in nature yet estimates of temporal variation in the direction and intensity of natural selection are few. Previous work on threespine stickleback (*Gasterosteus aculeatus*) has revealed that dorsal and pelvic spines are a defense against gape-limited predators but may be detrimental against grappling insect predators. In this study, we examined a 15-year database from an endemic population of threespine stickleback to look for evidence of temporal shifts in exposure to these diver-

gent predation regimes and correlated shifts in selection on spine number. For juveniles, we detected selection for increased spine number during winter when gape-limited avian piscivores were most common but selection for decreased spine number during summer when odonate predation was more common. For subadults and adults, which are taken primarily by avian piscivores, we predicted selection should generally be for increased spine number in all seasons. Among 59 comparisons, four selection differentials were significant (Bonferroni corrected) and in the predicted direction. However, there was also substantial variability in remaining differentials, including two examples with strong selection for spine reduction. These reversals were associated with increased tendency of the fish to shift to a benthic niche, as determined from examination of stomach contents. These dietary data suggest that increased encounter rates with odonate predation select for spine reduction. Strong selection on spine number was followed by changes in mean spine number during subsequent years and a standard quantitative genetic formula revealed that spine number has a heritable component. Our results provide evidence of rapid morphological responses to selection from predators and suggest that temporal variation in selection may help maintain variation within populations. Furthermore, our findings indicate that variable selection can be predicted if the agents of selection are known." 3887. Relyea, R.A. (2002): The many faces of predation: How induction, selection, and thinning combine to alter prey phenotypes. *Ecology* 83(7): 1953-1964. (in English). ["Populations in nature face a number of factors that can alter their traits and subsequent performance. Predation is one factor that can have widespread effects on the mean trait value in a prey population because predators can impact prey traits through a number of processes. Predators can directly induce prey phenotypes through visual and chemical cues, predators can indirectly alter prey phenotypes by thinning the prey population (thereby reducing competition), and predators can cause selection on prey phenotypes through nonrandom killing. Ecologists are beginning to understand each of these three processes in isolation, but these processes act on prey phenotypes simultaneously, and we lack information on the relative importance of these processes in determining the final phenotype of prey. I used a system of gray treefrog tadpoles (*Hyla versicolor*) and dragonfly predators (*Anax longipes*) to determine the separate and combined impacts of induction, thinning, and selection on the behavior, morphology, and growth of tadpoles reared in aquatic mesocosms. Using combinations of hand thinning, cues emitted from caged predators, and lethal predators, I demonstrated that the impact of lethal predators on growth was mediated primarily through thinning, the impact on morphology was primarily through induction, and the impact on behavior was affected similarly through thinning and induction. Surprisingly, while we know from numerous studies that the dragonflies kill tadpoles nonrandomly, selection did not have a significant impact on the final phenotypes of the tadpoles. This work appears to be the first study that identifies the relative magnitudes of the three predatory processes on a suite of prey phenotypes. The three processes can have opposing or supporting effects, the relative magni-

tudes of which likely differ among systems, illustrating why we often observe contradictory results when we examine the impact of lethal predators on prey phenotypes. Thus, it is important that we identify the mechanisms underlying the outcomes of predation, rather than simply observing the outcomes and then inferring which processes are responsible." 3888. Ribeiro, R.P.; Hayashi, C.; Martins, E.N. (2002): Aquatic systems evaluation under controlled conditions. *Acta Scientiarum Universidade Estadual de Maringa* 24(4): 987-996. (in Portuguese with english summary). ["The present experiment was conducted to evaluate three different diets for *Leporinus macrocephalus* post-larvae (Garavello & Britski) (Characiformes, Anostomidae) in controlled aquatic systems. Data were subjected to path coefficient analysis, consisting of multiple regression expansion, when complex interrelations are involved. The selected dependent variables were gut repletion degree (GR), phytoplanktonic organisms biomass (FITV) and spineless organisms biomass, plus odonata egg (ZOOV). The results allow the conclusion that the methodology was efficient to evaluate the diets inside the complex aquatic system, and the variables' selection, as well as the proper data collection, show relevance in the results quality." 3892. Switzer, P.V. (2002): Individual variation in the duration of territory occupation by males of the dragonfly *Perithemis tenera* (Odonata: Libellulidae). *Annals of the Entomological Society of America* 95(5): 628-636. (in English). ["In the dragonfly *Perithemis tenera* Say, males defend territories around oviposition sites and defense of a site is critical for reproductive success. This study first demonstrated that individual males varied consistently in how long they defended a particular territory within a day (their "tenure") and in the quality of the sites they defended. I then investigated a number of factors that may have affected territory tenure and may have led to the observed variation among males. Territory occupations that ended "voluntarily" were significantly longer than those that ended because the male was evicted from his territory. For voluntary desertions, tenure duration was unrelated to age, wing length, the amount of time the male fought that day, or site quality. However, tenure durations were longer for males that arrived earlier in the day than for those that arrived later, and consistent differences existed among males in arrival time. Furthermore, tenure durations were longer when males had successfully mated than when they did not mate; available evidence suggests that this pattern may be because mating success causes them to stay longer. Thus, the results suggest that the problem of explaining tenure duration in *P. tenera* can be largely broken down into identifying factors that affect a male's likelihood of being evicted and his relative arrival time. Overall, males that defended better sites and males that had longer wings were territorial for fewer total days. Of these two factors, site quality seems to have a larger effect than wing length on the number of days, suggesting that males may incur an increased cost by defending sites that are more attractive to other males." 3894. Thompson, J.E.; Ankney, C.D. (2002): Role of food in territoriality and egg production of Buffleheads (*Bucephala albeola*) and Barrow's Goldeneyes (*Bucephala islandica*). *Auk* 119(4): 1075-1090. (in English). [oas 14 "Buffleheads (*Bucephala albeola*) and the North American population of Barrow's Goldeneyes (*Bucephala islandica*) typically breed in boreal and montane regions where food is less available relative to most habitats used by temperate nesting ducks. We investigated diets and digestive organ morphology of sympatrically breeding female Buffleheads and Barrow's Goldeneyes in central British Columbia. Because those congeners exhibit interspecific aggression in defense of breeding territories, we predicted that competition for

food could be a principal factor in evolution of that behavior. We also hypothesized that breeding Buffleheads would show greater variation in digestive organ morphology than Barrow's Goldeneyes because of their smaller body size and consequently greater reliance on their diet to meet nutritional requirements for egg production. Both species fed predominantly on aquatic insects during all reproductive periods, particularly larvae of damselflies (Zygoptera), midges (Chironomidae), and phantom midges (Chaoborinae). Plant foods, primarily seeds of submergent and emergent vegetation, generally represented <15% of diets in both species. Diets of breeding female Buffleheads and Barrow's Goldeneyes were similar throughout reproduction, hence competition for food has likely been a factor in evolution of territorial aggression between those species. The digestive tract morphology of Buffleheads was more variable than that of Barrow's Goldeneyes suggesting that the former relied more on dietary nutrients during reproduction than did their larger congener." 3895. Tsunoda, W. (2002): External morphology of the giant water bugs, *Diplonychus japonicus* VUILLEFROY and *D. major* ESAKI (Hemiptera: Belostomatidae), in Fukushima and Kanagawa Prefecture. *Science Report of the Yokosuka City Museum* (49): 23-34. (in English). ["*Diplonychus japonicus* and *D. major* are two morphologically closely related species. It is difficult to distinguish them from each other simply by size and body color. Therefore, I carefully compared these two species with regard to external morphology in the hope of identifying sufficient morphological differences to separate the two. Generally *D. major* is bigger than *D. japonicus*, but some individuals of *D. major* are smaller than the bigger ones of *D. japonicus*. A further difference concerns proboscis length, which in *D. japonicus* is longer than in *D. major*. In the field, *D. major* feeds on dragonfly nymphs and larval amphibia, while *D. japonicus* feeds mainly on snails such as Physidae. Therefore, the different proboscis lengths appear to represent morphological adaptations to their different feeding habits." 3896. Turgeon, J.; McPeck, M.A. (2002): Phylogeographic analysis of a recent radiation of *Enallagma* damselflies (Odonata: Coenagrionidae). *Molecular Ecology* 11(10): 1989-2001. (in English). ["A phylogenetic hypothesis revealed two recent radiations among species of *Enallagma* damselflies, and extensive ecological work suggests that both adaptive and nonadaptive processes are involved in these radiations. We analysed the geographical pattern of genetic variability at 868 bp of mitochondrial DNA (mtDNA) among 283 individuals of 5 species displaying little ecological differentiation to identify the ancestral lineage, support their independent evolutionary trajectories and identify historical events and the underlying mechanism for one of these radiations. Nested clade analysis results clearly support a past event of range fragmentation in *E. hageni*. These Atlantic and Continental *hageni* races experienced distinct dispersal histories and still maintain nearly nonoverlapping ranges All four other species derive from the Continental *hageni*. Whereas three species endemic to the Atlantic coastal plain show little genetic variation, *E. ebrium* shared several haplotypes with the Con-

tinental hageni. Contrasting levels of genetic differentiation between *E. hageni* and *E. ebrium* in geographical areas associated with distinct events of *E. hageni*'s recent history support the recent origin of this species. Altogether, our results are compatible with a process of radiation via divergence in mate recognition systems within the Continental hageni race following secondary contacts between putative refugial races." 3899. Amweg, E.L.; Stuart, D.L.; Weston, D.P. (2003): Comparative bioavailability of selenium to aquatic organisms after biological treatment of agricultural drainage water. *Aquatic Toxicology* 63(1): 13-25. (in English). ["Selenium (Se) is naturally abundant in the soils of the western San Joaquin Valley, California, USA. Intense agricultural activity in this region requires irrigation which leaches Se into surface waters draining to the San Joaquin River. Se water contamination and subsequent accumulation in wildlife is a serious problem in the Central Valley of California, and the subject of increasingly intensive regulatory action. Algal-bacterial selenium reduction (ABSR) is a potential new treatment approach to reduce Se in agricultural drainage, and an ABSR demonstration facility was examined with respect to its Se removal efficiency and effect on Se bioavailability and bioaccumulation. Water samples were taken to study treatment effects on Se speciation. Invertebrate tissue Se concentrations in the ABSR ponds were monitored for 2 years. Laboratory-based algal bioaccumulation tests and in situ microcosms with a variety of invertebrates were also used to address differences in Se bioavailability before and after ABSR treatment. The ABSR system removed about 80% of the total influent Se; however, microbial and algal activity produced selenite and organic Se, the combined concentration of which increased 8-fold during treatment. As a result of the greater bioavailability of selenite and organic Se, relative to the selenate of the influent, treatment contributed to greater Se concentrations in effluent-exposed organisms. ABSR-treated water

produced Se concentrations in biota 2-4 times greater than organisms exposed to untreated water. The bioavailability of Se in the treated water was 2-10 times greater than Se in the influent. The shift to more bioavailable Se forms due to biological treatment is inherent in system design, and makes it difficult to weigh the ecological benefits of a reduction in total Se loadings from a regional perspective against the greater toxicological risk to biota in the vicinity of the effluent." 3900. Anlauf, A.; Kleinwachter, M.; Eggers, T.O. (2003): Modification of groynes and guide dykes at Elbe riverbanks: Impact of construction on the habitats of animals. Oral presentation at the Conference: Lowland River Rehabilitation, NCR & RIZA (Wageningen, September/October 2003) [Modifizierung von Buhnen und Leitwerken im Uferbereich der Elbe: Einfluss auf die Habitatbildung für Tiere] & Poster: 1 p. (in English). ["The river Elbe in Germany between the Czech Republic and the weir in Geesthacht has a length of 685 km and is characterized by about 6900 groynes and 300 km of stone-fixed embankments and dykes. The development of the embankment is strongly influenced by these constructions. Nevertheless many banks appear to have natural conditions. In the last years some special modifications of groynes and guide dykes were built in the field at different sections of the River Elbe. The aim of the investigations on different types of groynes, i.e. with an angle shape or with gaps in the groyne body is to change the hydromorphological regime in the groyne fields and increase structural dynamics. Similar aims are described from the banks behind guide dykes, which are constructed with gaps or tube outlets. The modifications showed direct influences on the appearance of species. The succession of different habitat types for fish, macrozoobenthos or carabid beetles in modified constructions is compared to conventionally regulated riverbanks. The results lead us to recommendations for the rehabilitation of riverbanks without abandonment of the constructions necessary for navigation." (Authors). The distribution pattern of *Stylurus flavipes* within a groyne field is presented. This species lives only in sandy-silty substrate within the groyne field; abundances at sample site are demonstrated.] Address: Eggers, T., Zool. Inst., TU Braunschweig, Fasanenstr. 3, D-38092 Braunschweig, Germany. E-mail: t.eggers@tu-bs.de

3906. Bass, D. (2003): A comparison of freshwater macroinvertebrate communities on small Caribbean islands. *Bioscience* 53(11): 1094-1100. (in English). ["An ongoing survey of macroinvertebrates inhabiting the relatively unstudied freshwater habitats on 14 small Caribbean islands was initiated in 1991. These collections have yielded almost 200 species; when these species are combined with collections previously made by other researchers, a total of at least 328 freshwater macroinvertebrates are now known from these islands. The dominant taxa on the islands include several species of

snails, shrimps, mayflies, dragonflies, damselflies, beetles, and other insects. Many of these species have fairly widespread distributions across the islands. Most stream species are associated with leaf packs, and most pond species are associated with aquatic macrophytes. As is typical of tropical island systems, the macroinvertebrate faunas of these islands are sparse, most likely because of their oceanic origin, their small size, and the frequent disturbances to their freshwater environments." (Author) The islands studied in this investigation include Barbados, Tobago, Grenada, St. Lucia, Dominica, Montserrat, Nevis, St. Kitts, Saba, Antigua, Cayman Brae, Little Cayman, Grand Cayman, and Guanaja. A total of 39 odonate species represented at the listed islands is compiled; the species are not specified.] Address: Bass, D., Department of Biology, University of Central Oklahoma, Edmond, OK, 73034, USA. 3913. Buczyński, P. (2003): Dragonflies (Odonata) of the Landscape Park of the Iława Lake District. *Rocz. nauk. Pol. Tow. Ochr. Przyr. "Salamandra"* 7: 65-85. (in Polish with English summary). [In the years 1998-2002 the dragonflies of the Landscape Park of the Iława Lake District were studied (N Poland, 53°37'-53°51' N, 19°22'-19°41' E). This park (25279 ha) with a diverse, postglacial relief is mainly covered with forests (62%) and lakes (19%). Small running waters, located in forests, and peatbogs are numerous, small waterbodies and ponds (situated on meadows) are less numerous. The 47 dragonfly species collected represent approximately 65% of the national odonate fauna (Mielewczyk 1990, 1997) and 77% of fauna of the lake districts of NE Poland. The forest character and geographical position are the natural factors limiting the dragonfly species

richness of this area. These are also the reasons why Mediterranean and/or open biotope species do not find it suitable for development. Of special interest are: *Sympecma fusca*, *S. paedisca*, *Coenagrion lunulatum*, *Erythromma viridulum*, *Aeshna juncea*, *A. subarctica elizabethae*, *A. viridis*, *Somatochlora arctica*, *Orthetrum coerulescens*, *Sympetrum pedemontanum*, *Leucorrhinia albifrons*, and *L. pectoralis*.] Address: Buczyński, P., Dept of Zool., Mariae Curie-Skłodowska University, Akademicka 19, PL-20-033 Lublin, Poland. 3918. Bueno, A.A.P.; Bond-Buckup, G.; Ferreira, B.D. (2003): Estrutura da comunidade de invertebrados bentônicos em dois cursos d'água do Rio Grande do Sul, Brasil. *Revista Brasileira de Zoologia* 20(1): 115-125. (in Portuguese, with English summary). [Community structure of benthic invertebrates in two watercourses in Rio Grande do Sul State, southern Brazil. The macrobenthic communities from two watercourses in Rio Grande do Sul State, Brasil, were sampled with a Surber sampler, monthly, from September 1999 to August 2000, in one of the creeks forming Tainhas River (29°15'30,2"S, 50°B'12,5"W), around São Francisco de

Paula city and in Mineiro Creek (29°30'0,2"S, 50°46'50"W), around Taquara city. "At each sampling point, physical and chemical variables of the waters were registered. [...]. Dissolved oxygen, pH and stream speed were very similar for both environments, whilst conductivity had extreme values. Insects, crustaceans, acari, and molluscs dominated in the samples. Abundance, richness and diversity indexes in Tainhas subsidiary had relatively higher average values than Mineiro Creek. Similarity matrix groupings between sampling units indicate three groups. Our research revealed important characteristics of the ecology and distribution of benthic invertebrates, information that can subsidise future environmental monitoring in the region of São Francisco de Paula and Taquara." (Authors) In table 2 absolute and relative frequencies of the taxa, including "Coenagrionidae" are presented.] Address: Bueno, Alessandra, Departamento de Zoologia, Instituto de Biodiversidade, PPC Biologia Animal, Universidade Federal do Rio Grande do Sul, Ave. Bento Gonçalves 9500, prédio 43435, 91 SOT-970 Porto Alegre, Rio Grande do Sul, Brasil. 3919. Büttger, H.; Finch, O.-D. (2003): Libellenzöosen an Krebscherengraben der südlichen Wesermarsch unter besonderer Berücksichtigung der FFH-Art "Aeshna viridis" EVERSMANN, 1936 (Insecta: Odonata). Oldenburger Jahrbuch 103: 317-331. (in German with English summary). ["In the southern part of the Wesermarsch district in Lower Saxony, Germany the coenoses of dragonflies of 21 ditches were examined during the summer 2001. Several structural parameters of the ditches and the vitality of *Stratiotes aloides* were measured. A total of 17 dragonfly species was recorded, two of which occur only in the vicinity of the examined ditches. *Coenagrion pulchellum*, red listed as "endangered" in Germany, was the dominant species. *Brachytron pratense*, also "endangered", was present with a few individuals. *A. viridis* is "threatened of extinction" in Lower Saxony as well as nation-wide. This species was recorded at six ditches with a maximum of four individuals. At single ditches six to thirteen species were established. *A. viridis* is a strictly protected species of common interest" according to the European Flora-Fauna-Habitat Directive (FFH). Therefore, monitoring is strongly recommended for this species. Conservation measures for the stenotopic dragonfly should include careful, regular and yearly alternating maintenance of ditches. Populations of *Stratiotes aloides* hopefully can be managed in this way and simultaneously the discharge conditions, which are important for agricultural purposes, will be secured." (Authors)] Address: Finch, O.-D., Universität Oldenburg Fk 5 / Bio-, Geo- und Umweltwissenschaften, AG Terrestrische Ökologie, D-26111 Oldenburg, Germany. E-mail: oliver.d.finch@uni-oldenburg.de

3920. Burt, J. (2003): Aquatic macroinvertebrates of an intermittent stream in the arid Hajar Mountains, Oman. *Tribulus* 13(2): 14-22. (in English). ["Aquatic macroinvertebrates were collected from six habitats in two permanently flowing sites to Wadi Qahfi, northern Oman. A total of 38 taxa were identified, many to taxonomic levels previously unrecorded for aquatic fauna in Arabia. Overall richness was comparable between airt habitats sampled. While very little regional information is available for identification of aquatic macroinvertebrates, the combination of regional descriptive information with foreign keys for aquatic stages has proven to be a

valuable approach. Recommendations are made for appropriate levels of classification for the major taxonomic groups, and references are provided to assist in identification." (Author) The possibilities to identify Odonata are briefly discussed, and in Tab. 3 as result of the survey, Gomphidae (indet.), Paragomphus, Libellulidae (indet.), and Coenagrionidae (indet.) are listed.] Address: Burt, J., Dept natural & Quantitative Sciences, Zayed Univ., PO Box 19282 Dubai, U.A.E. 3921. Bußmann, M. (2003): Die Wiederbesiedlung der oberen Ennepe durch die Blauflügel-Prachtlibelle *Calopteryx virgo* (L., 1758) (Odonata, Zygoptera). *Natur und Heimat* 65(4): 109-117. (in German). [The upper reaches of the river Ennepe (Nordrhein-Westfalen, Germany) was surveyed for *C. virgo* on 17 June 1997 and repeated on 26/ 27 June 2002. The species spread closer to the epirhithral and krenal of the river. Population density had increased. The current extension of habitat use is documented and extensively discussed.] Address: Bußmann, M., Amselweg 18, D-58285 Gevelsberg, Germany

3922. Buttstedt, L. (2003): Wiederbesiedlung der mittleren Unstrut und unteren Helme in Thüringen durch stenöke Fließgewässerarten. *Thüringer Faunistische Abhandlungen* 9: 73-76. (in German with English summary). [Following a significant improvement of the water quality of the rivers Unstrut and Helme (Thüringen, Germany), in the mid of the 1990s *Calopteryx splendens* and *Platycnemis pennipes* could be re-observed. Their populations grow very strong in the succeeding years, and both species are common now. In 2003, exuviae, larvae, and imagines of *Gomphus vulgatissimus* could be traced along the Unstrut and the lower reach of the Helme. Imagines of *Ophiogomphus cecilia* have been observed along the Unstrut in 2003 too. It is supposed that the recolonisation process originating from Elbe and Saale now has reached northern Thuringia.] Address: Buttstedt, L., Ziegeleistr. 26, D-06536 Roßla, Germany

3923. Cabela, A.; Chovanec, A.; Ellinger, N.; Gressler, S.; Grötzer, C.; Pascher, K.; Raab, R.; Straif, M.; Teufl, H. (2003): Maßnahmenkatalog für die neu geschaffenen Uferstrukturen auf der Donauinsel. *Denisia* 10: 215-226. (in German with English summary). ["The results obtained in the Danube Island Monitoring Programme are the basis for management measures which should contribute to improve the migration linkages on the island itself and to provide new habitats particularly in the northern and central parts of the Danube Island." (Authors) Management measures from the odonological point of view are discussed.] Address: Raab, R., Anton Bruckner-Gasse 2/2, A-2232 Deutsch-Wagram, Austria. E-mail: rainer.raab@gmx.at

3924. Cham, S. (2003): Factors influencing the distribution of the White-legged Damselfly *Platycnemis pennipes* (Pallas) in Great Britain. *J. Br. Dragonfly Society* 19(1/2): 15-23. (in English). [*P. pennipes* is common and widespread throughout much of central and eastern Europe. In Britain it occurs south of the Wash (latitude 53 °N), and its distribution is associated with linear habitats, i.e. the larger rivers and their tributaries. It is absent from Ireland. It occurs in 6.4 per cent of the 10km squares from which Odonata records are available. This paper examines some of the factors influen-

cing the distribution of *P. pennipes* with reference to its often-quoted susceptibility to pollution. Heavy boat traffic (along the River Great Ouse in Bedfordshire and Huntingdonshire) seems to have no negative effect on the species. The study concludes that there is little evidence to support the view that the species is more susceptible to pollution than other species. It would appear to be more influenced by the habitat and the structure of bankside vegetation.] Address: Cham, S., 24 Bedford Avenue, Silsoe, Bedford MK45 4ER, UK

3925. Chelmick, D. (2003): A significant migration of the Red-veined Darter *Sympetrum fonscolombii* (Selys) in southern Spain. *J. Br. Dragonfly Society* 19(1/2): 35-36. (in English). ["In October 2002, near the port of Tarifa, situated in Andalucia at the southern-most tip of Spain, the author observed a significant migration of the Red-veined Darter *Sympetrum fonscolombii* (Selys). During a two and half hour period between 1500h and 1730h local time, an estimated total of 450,000 individual insects were observed migrating along the coast." 3926. Chovanec, A.; Schiemer, F. (2003): Die Donauinsel in Wien als ökologischer Korridor? Untersuchung der Besiedlung neu geschaffener Uferstrukturen im Stauraum Freudenau - Hintergrund, Projektidee und zusammenfassende Darstellung. *Denisia* 10: 27-51. (in German with English summary). ["During the construction of the hydroelectric power plant Vienna-Freudenau, the previously straight shoreline of the 21 km long Danube Island was restructured by creating backwaters, coves, gravel banks, and pools. This paper describes the design and the results of a four year monitoring programme investigating the colonisation and successional processes at the study sites. The results show that the sites isolated from the Danube serve as stepping stone biotopes and breeding ponds for dragonflies, amphibians and reptiles. Rheophilic fish species colonise side channels connected with the Danube and indicate a longitudinal connectivity on a landscape scale due to a corridor function of the Danube Island." (Authors)] Address: Chovanec, A., c/o Umweltbundesamt, Spittelauer Lände 5, A-1090 Wien, Austria. E-mail: chovanec@ubavie.gv.at

3927. Clausnitzer, H.-J. (2003): Wie effektiv sind Naturschutzgebiete? Untersuchungen am Beispiel der Libellen (Odonata) im Landkreis Celle (Niedersachsen). *Braunschweiger naturkundliche Schriften* 6(4): 789-798. (in German with English summary). [A total of 53 odonate species are reproducing regularly in the district Celle, Germany. 28 of these species are listed as "Endangered" in the German Red List of threatened or vulnerable Odonata. 14 of these endangered dragonflies are found mainly within the boundaries of nature reserves, 6 species are evenly distributed in and outside nature reserves, and 8 species build up their greatest populations outside nature reserves. Protected by nature reserves are bog and fen dwelling species, while species of other biotopes (e.g. species of running waters) have greater populations outside of nature reserves. But even the latter areas (ponds) are in possessions of the public sector and looked after by nature conservation authorities. In general, the situation of endangered species is more unfavourable outside of protected areas.] Address: Clausnitzer, H.-J., Eichenstr. 11, D-29348 Eschede, Germany

3928. Clausnitzer, V.; Martens, A.; Suhling, F. (2003): From desert to forest: diversity of African Odonata. *Gesellschaft für Tropenökologie*. 16. Jahrestagung in Rostock. Abstracts: 32. (in English). [Verbatim: The two dragonfly projects of BIOTA (Biodiversity Transect Analysis in Africa; E07 and S08) work on diversity patterns of dragonflies in eastern and southwest Africa. Main topics of the joined studies are the effects of habitat fragmentation on species composition and genetic isolation, changes in diversity patterns along natural and anthropological gradients and adaptations to seasonal habitat conditions. Results of these studies are used to define indicator species and monitoring programmes for habitat quality and rapid assessments. Nearly all species found in Namibia are common in savannah habitats in East Africa and even West Africa as well. Most of these species are migratory and colonise seasonal wetlands even in an otherwise very dry matrix (temporal and spatial). The genetic variation between East and Southwest African populations of such species, e.g. *Crocothemis erythraea* or *Trithemis kirbyi* is very small. Species with adaptations to distinct habitats, e.g. forests or spring brooks on the other hand show genetic differences between isolated populations. *Coryphagrion grandis*, which occurs in the fragmented coastal forest regions of East Africa, shows high sequence diversity between populations, which correlates with the distance and therefore age of the single forest fragments. Our results from the BIOTA transect from east to southwest Africa allow biogeographic discussions about past and present distribution patterns of dragonflies and about shifts in biodiversity patterns with changing climatic and/or environmental conditions. Results of both projects also indicate that Odonata are good indicators for assessing anthropogenic impacts on inland waters.] Address: Clausnitzer, Viola, Liebenauer Str. 180, D-06110 Halle/Saale, Germany. 3934. David S. (2003): Results of the monitoring of the dragonflies (Insecta : Odonata) in the catchment of the Pariz stream (SW Slovakia). *Ekológia (Bratislava)* 22, Supplement 2): 320-332. (in English with Slovakian summary). [Between 2000 and 2002, in the Pariz stream catchment a monitoring of the dragonflies and their habitats was realised. A total of 34 species were recorded, 17 of these are registered in the Slovak Red List, and 8 species are protected by law in the Slovak Republic. The most endangered and rare species in the study area are *Coenagrion scitulum*, *Libellula fulva*, *Brachytron pratense*, *Epitheca bimaculata*, and *Soma-tochlora flavomaculata*. 26 odonate species prefer stagnicolous water habitats, only *Calopteryx splendens* and *Platycnemis pennipes* are rheophilous. *Crocothemis erythraea*, *Anaciaeschna isosceles*, and *Aeshna mixta* are considered as migrant species. The dragonfly community structure and the types of habitat are described using of CANOCO statistical packages (indirect gradient analysis, procedure PCA, DCA). The stagnicolous *Lestes-Sympetrum-Aeshna* and the eurytopic *Orthetrum-Libellula depressa* odonatocoenosis but no rheophilous communities were identified. The importance of the man-made water habitats (sand-pits, marshland-pit, drain-streams and ponds) for Odonata is stressed.] Address: David, S., ÚKE SAV, Akademická 2, SK-94901 Nitra, Slovakia. E-mail: stanislav.david@savba.sk

3935. David S. (2003): The Bioindication of Anthropogenic Changes Water Biotops (extractive sites) Using the Dragonflies (Insecta: Odonata). In: Olah, B. (ed.): IV. Ekologicke dni, SEKOS pri SAV - Ekologicke stiidie V., Banska Stiavnica, 7.-8. oktober 2003. SEKOS, Banska Stiavnica: 174-184. (in Slovakian with English summary). ["During the years 1986-2003, the monitoring of the dragonflies and their extractive sites habitats

(gravel pits, moorland pits and silty pits in some localities was realised. From different parts of Slovakia) we selected 7 localities. There were 39 species (n = 1539 specimens) of dragonflies recorded. Six of them are protected by law in the Slovak Republic and 16 species are registered in the Slovak Red List." The nature-conservation value of disturbed habitats is high due to the highest values of diversity and equitability. "The species data and 4 environmental variables (altitude, water surface area, depth of water and vegetation cover) at 7 sites were analysed by methods of Principal component analysis (PCA) and Canonical correspondence analysis (CCA), using CANOCO software. The ordination methods established the importance of current condition of the habitats but not of the way of their formation or disturbance." The altitude limits species diversity. The sensitivity of the dragonflies on environmental factors of the localities was confirmed. Dragonflies are suitable indicators of the current succession stage of aquatic habitats.] Address: David, S., ÚKE SAV, Akademická 2, SK-94901 Nitra, Slovakia. E-mail: stanislav.david@savba.sk

3936. De Block, M.; Stoks, R. (2003): Adaptive sex-specific life history plasticity to temperature and photoperiod in a damselfly. *Journal of Evolutionary Biology* 16(5): 986-995. (in English). ["We investigated four predictions about how temperature, photoperiod and sex affect the life history plasticity and foraging activity of *Chalcolestes viridis*. (i) As predicted, increased temperatures increased foraging activity and growth rates, but in contrast with the prediction, late photoperiod (high time stress) did not affect foraging activity and growth rate. (ii) Unexpectedly, the increase in growth rate at increasing temperatures was not larger under high time stress. (iii) As predicted, age and size at emergence decreased at higher temperatures and at the late photoperiod. Temperature-induced life history shifts were direct or the result of behavioural growth mediation depending on the temperature range. Photoperiod-induced life history shifts were direct. (iv) As predicted, males emerged before females but at a smaller size. The degree of sexual size dimorphism was influenced by the joint effects of temperature and photoperiod. We could only detect genetic variation in size plasticity to photoperiod. The match between the sex-specific life history responses to temperature and photoperiod and predictions by relevant optimality models suggests adaptive life history plasticity to these variables." (Authors)] Address: De Block, M., Evolutionary Biology Group, University of Antwerp, Groenenborgerlaan 171, B-2020, Antwerp, Belgium. E-Mail: mdeblock@ruca.ua.ac.be

- 3949.** Elegem, B. van; Knijf, G. de (2003): An exceptional dragonfly community in the polder of Kruikebe, Bazel and Rupelmonde (East-Flanders, Belgium). *Gomphus* 19(1): 13-29. (in Dutch with English and French summaries). ["The polder of Kruikebe, Bazel and Rupelmonde, Belgium is one of the main open areas in the valley of the river Scheldt. This area was investigated on its Odonata fauna during spring and early summer of 2000. A total of 22 Odonata species were observed and 4 of them are included in the Red list of Flanders: *Brachytron pratense*, *Libellula fulva*, *Cordulia aenea*, and *Erythromma najas*. The presence of these species is a good indication of a dragonfly community of lowland peatbogs. *Libellula fulva* is the most common Anisoptera in spring and the species has its main

stronghold in Flanders at the creek of Rupelmonde. Due to a lack of visits in July and especially August we expect that several other species, especially from the genera *Aeshna* and *Sympetrum* could be found in this polder." (2003): Comunidade de Odonata [Insecta] em áreas naturais de Cerrado e monocultura no nordeste do Estado de São Paulo, Brasil: relação entre o uso do solo e a riqueza faunística. *Revista Brasileira de Zootaxia* 20(2): 219-224. (in Portuguese, with English summary). ["Odonata community on natural areas of Cerrado

and monoculture of northeastern SSo Paulo State, Brazil: relationship between land use and richness. Stream ecosystems may be strongly influenced in different ways by land use. The effects of land-cover patterns on Odonata community were studied in eight streams and seven lakes-dams of northeastern São Paulo State. The pattern analyzed was monoculture (sugar cane) vs. nature reserve in terms of Odonata species richness and similarity. Eighty-five Odonata species were sampled. The species richness was higher in the monoculture (33 species) than nature reserve (30 species) and 22 species were common to both areas. There was not verified relationship between land use and physical or chemical characteristics of the streams or lakes-dams water. These results suggest that some Odonata species are benefited and other affected by anthropogenic actions, although more studies are necessary to evaluate this hypothesis. There were ten new records for São Paulo State [*Neoneura sylvatica*, *Coryphaeschna adnexa*, *Erythemis haematogastra*, *E. mithroides*, *Micrathyria longifasciata*, *M. pseudeximia*, *Planiplax machadoi*, *Lauromacromia* sp., *Tibiagomphus* sp. and *Aeschnosoma* sp.]" (Authors)] Address: Ferreira-Peruquetti, Patrícia, Departamento de Hidrobiologia, Universidade Federal de São Carlos. 3961. Garrison, R.W.; Ellenrieder, N. von; O'Brien, M. (2003): An annotated list of the name-bearing types of species-group names in Odonata preserved in the University of Michigan, museum of zoology. Occasional papers of the museum of zoology, University of Michigan 736: 73 pp. (in English). ["This catalog presents a listing of all species-group names associated with Odonata specimens currently housed in the type collection in the University of Michigan Museum of Zoology (UMMZ), Ann Arbor, MI. The names represent species described by P.P. Calvert, L.K. Gloyd, F. Förster, M.A. Lieftinck, C.H. Kennedy, F. Ris, E.B. Williamson and others, and transcription of data labels, reference and current status have been included. A lectotype is designated for *Argia cyathigera* Navás in order to stabilize that name. The following are new synonyms: *Mecistogaster garleppi* Förster, 1903 = *Mecistogaster buckleyi* McLachlan, 1881; *Argia augustana* Navás, 1934 = *Argia medullaris* Hagen in Selys, 1865; *Argia dagnina* Förster, 1914 = *Argia indicatrix* Calvert, 1902; *Argia machadina* Förster, 1914 = *Argia difficilis* Selys, 1865; *Argia medinensis* Navás, 1935 = *Argia gerhardi* Calvert, 1909. Of 389 names, 85 are considered junior synonyms." (Authors) Taxa of the following families are treated: Amphipterygidae, Calopterygidae, Chlorocyphidae, Dicteriadidae (Heliocharitidae), Polythoridae, Lestidae, Perilestidae, Megapodagrionidae, Platystictidae, Protoneuridae, Pseudostigmatidae, Platynemididae, Coenagrionidae, Aeshnidae, Gomphidae, Cordulegastridae, Corduliidae, Libellulidae. The paper is more than a study on nomenclature and taxonomy, for it contains many detailed information on localities and collecting details indispensable for workers in the history of odonatology.] Address: Garrison, R.W., Research Associate, Natural History Museum of Los Angeles County, Exposition Boulevard 900, CA 90007, USA. E-mail: rwgarrison@earthlink.net

3962. Gibson, V. (2003): Communication between the sexes at the end of copulation: a study of three species of Anisoptera. *J. Br. Dragonfly Society* 19(1/2): 44-46. (in English). ["There are many aspects of signalling that we know little about. For example how does a female signal to a male in tandem that she has completed oviposition? What signals are exchanged between the sexes at the end of copulation?" (Miller, 1995). Using a camcorder, sequences of *Aeshna mixta*, *A. juncea*, and *Sympetrum striolatum* have been analysed to find answers to these questions. It was found that "wing clapping behaviour" in *A. mixta* and *A. juncea*, "wing touching behaviour" in *A. mixta*, and "wing lifting" in *S. striolatum* can be interpreted as signals between the partners of the tandem. "The wing lifting behaviour described here provides a possible answer to the question 'how does the female indicate to the male that she is

ready to oviposit?' The video sequences seen in slow playback [...] do seem to show that the female action of wing touching and lifting is a definite signal to the male. Since uncoupling and flight soon follow, it is possible that it is a 'ready to oviposit' signal. The case is strongest for *S. striolatum*, where the male's wings are positively lifted rather than stroked, and where uncoupling and flight occur almost immediately on the cessation of wing lifting. This behaviour does not seem to be referred to elsewhere. The significance of the wing clapping is less obvious, but it is clearly a signal from the male to the female. Occurring, as it did, shortly before wing lifting, it might mean 'I have finished sperm transfer'. The third and last stage in prolonged copulation is the transfer of sperm within the female, although the stage is not as clear in darters as in some other Odonata (Miller, 1995). The male has no control over this stage and may be anxious to depart to avoid predators and interference from other males. Again, this behaviour does not seem to be referred to elsewhere." (Author)] Address: Gibson, V., 76 Pexton Road, Sheffield S4 7DA, UK

3963. Goddard, D. (2003): Inverted emergence recorded in the Common Darter *Sympetrum striolatum* (Charpentier). *J. Br. Dragonfly Society* 19(1/2): 39. (in English). [Verbatim: On Sunday 18 August 2002, whilst leading the British Dragonfly Society afternoon walk around the Bennerley Marsh recording area, we came to the de-acidification pits where the group looked for exuviae. I came across the inverted exuvia of *S. striolatum* which was attached to a dried leaf of a *Bulrush Typha latifolia* approximately 150mm above the water level. This is the first time that I have observed such an indication of inverted emergence in this particular species and I have not come across this being noted in any of the literature.] Address: Goddard, D., 30 Cliffe Hill Avenue, Stapleford, Nottingham NG9 7HD, UK

3964. Goddard, D. (2003): The domestic cat: a new dragonfly predator. *J. Br. Dragonfly Society* 19(1/2): 39. (in English). [Verbatim: On Saturday 10 August 2002, at approximately 1430h GMT, I witnessed what I thought was a very unlikely dragonfly predator. Two of our domestic cats acted together to chase a Migrant Hawker *Aeshna mixta* Latreille which was hawking over our garden pond. The chase took two or three minutes and the *A. mixta* did not seem to want to leave the area despite being chased by the cats. It eventually settled on the vegetation around the edge of the pond it was at this point that one of the cats pounced and caught the insect and consequently killed it. Once they had killed the insect they just left it on the lawn.] Address: Goddard, D., 30 Cliffe Hill Avenue, Stapleford, Nottingham NG9 7HD, UK

ded; main emphasis was given to *Oxygastra curtisii* which was recorded from several stretches of the river Ourthe. In addition, records of the stream dwelling species *Gomphus pulchellus*, *G. vulgatissimus*, *Onychogomphus forcipatus*, and *Cercion lindenii* are briefly commented upon.] Address: Goffart, P., Unité d'Écologie et de Biogéographie, 5, Place Croix-du-Sud, B-1348 Louvain-la-Neuve, Belgium. E-mail: goffart@ecol.ucl.ac.be

3967. González-Soriano, E.; Córdoba-Aquilar, A. (2003): Sexual behaviour in *Paraphlebia quinta* Calvert: male dimorphism and a possible example of female control (Zygoptera: Megapodagrionidae). *Odonatologica* 32(4): 345-353. (in English). ["The sexual behaviour and a case of male phenotypic dimorphism in *P. quinta* are described: black-winged (BW) males and hyaline-winged (HW) males. Similar to other territorial odonate species, some males defended a space that females used for oviposition while other males acted as satellites. Copulation took place in 2 stages which differed in abdominal movement orientation and duration. Copulation duration varied between morphs and was frequently disrupted. During disruption, the genitalia of both sexes disengaged although the tandem position (the male's abdominal appendices grasping the female's prothorax) was maintained. Disruptions, which took place during the first stage (a stage during which displacement of rival sperm occurs in most odonate species), were sometimes followed by emissions of sperm from the vagina. Male morphs exhibit striking behavioural differences: HW males do not defend territories, but BW males do, and the former copulate for longer and show more copulatory disruptions. Some stages of female behaviour are described and suggested as instances during which females may be exerting mate choice: females copulated on fewer occasions with HW males, copulations with this morph were longer but ovipositions were not, and sperm emissions (possibly, sperm from previous mates) and copulatory disruptions of BW males were less frequent. Because of these differences, it is suggested this is a unique species to test current ideas of female control in an insect order in which the idea of male "control" has been traditional." (Authors)] Address: Gonzalez-Soriano, E., Depto Zoologia, Inst. Biol., Universidad Autonoma, Apartado Postal 70-153, 04510 Mexico, D.F., Mexico. E-mail: esoriano@mail.ibiologia.unam.mx

3968. Gossum, H. van; Sánchez, R.; Cordero Rivera, A. (2003): Observations on rearing damselflies under laboratory conditions. *Animal Biology* 53(1): 37-45. (in English). ["Rearing damselflies under laboratory conditions is a promising means of solving a variety of biological questions. Therefore, in order to improve the success of future researchers we felt the need to indicate potential difficulties in carrying out rearing experiments. Laboratory crosses were obtained using virgin animals originating from natural populations in Belgium and Spain. Resulting offspring was maintained, under laboratory conditions, in small aquaria until emergence and in insectaries as adults. Our results show that keeping damselflies during their entire life cycle under artificial conditions can be very difficult. We suggest that future researchers should change water regularly, supply sufficient food, and rear animals at low density or even individually. Furthermore, suggestions are given on type of food, advisable laboratory conditions and female oviposition methodology." (Authors)] Address: Gossum, H.

3973. Hämäläinen, M. (2003): *Cryptophaea*, a new euphaeid genus and three new species of Caloptera damselflies from Thailand (Odonata: Euphaeidae, Calopterygidae). *Zool. Med. Leiden* 77(25): 441-454. (in English). [The euphaeid specimens from Doi Suthep (North Thailand) identified and redescribed by Asahina in 1987 as *Schmidtphaea schmidi* are not conspecific with the holotype of *S. schmidi* Asahina, 1978, from Manipur (North-east India), but represent a distinct new species described as *Cryptophaea saukra* gen. & spec. nov. *Bayadera vietnamensis* van Tol & Rozendaal, 1995 and *Schmidtphaea yunnanensis* Davies & Yang, 1996, are transferred to the genus *Cryptophaea* gen. nov. *Anisopleura trulla* spec. nov. from South Thailand is described and "*Caliphaea confusa* sensu Asahina, 1985" from Doi Inthanon (North Thailand) is described as *C. angka* spec. nov.] Address: Hämäläinen, M., Department of Applied Biology, P.O. Box 27, FIN-00014 University of Helsinki, Finland. E-mail: matti.hamalainen@helsinki.fi

3974. Hämäläinen, M. (2003): The 150 year anniversary of Selys' Synopsis des Caloptérygines. *Malangpo* 20: 196-200. (in English). [The paper acknowledges the outstanding work of Baron Michel-Edmond de Selys Longschamps (1813-1900) with special emphasis on the "Synopsis des Caloptérygines". The paper outlines the classification system and regional coverage of the species. App. 230 taxa have been known to Selys. At present, the number of the known Caloptera is already over 450 species. Many taxa await description, and the number of species in Caloptera is believed to pass the limit of 500 species.] Address: Hämäläinen M., Dept Applied Zool., P.O.Box 27, FIN-00014 University of Helsinki, Finland; E-mail: matti.hamalainen@helsinki.fi

3975. Hatchings, G. (2003): Another dot on the map - *Aeshna tuberculifera* from north-central Saskatchewan. *Argia* 15(3): 9-10. (in English). [Canwood, Saskatchewan, Canada; continuation of range extension of *A. tuberculifera*.] Address: Hatchings, G. E-mail: sea-trek@islandnet.com

3976. Hatchings, G. (2003): Observations of an ovipositing dragonfly frenzy in the rain. *Argia* 15(3): 8-9. (in English). [Oviposition of dozens of *Aeshna eremita* was taking place in a real down-pour, but it was "also fairly dark with the thick, black clouds covering the sun low on the horizon. This downpour which must have been like large water-filled balloons to a dragonfly's wing, didn't slow down their hectic flight but did cause some to do these somersaults in mid-air. I could easily make out their complete flips and the reason they perform mis - to rid themselves of the water they had accumulated, flinging it off in all directions. It was cool to see this at such close proximity and as a backdrop, the sound of thunder and the flash of lightning. [...] (Author)] Address: Hatchings, G. E-mail: sea-trek@islandnet.com

3977. Hatchings, G. (2003): Where do dragonflies go when they die? *Argia* 15(3): 9. (in English). [Saskatchewan, Canada, 24.VIII. 2003; several adults with tattered outer wing margins plunge onto the surface only to be trapped by the surface tension, where they end stuck upside down. "Now, I'm sure many of us have seen this behaviour and have noted how these dragonflies almost seem Osprey-like in how they can extract themselves from the surface, somersault in the air [...], and carry on. I've seen mating or battling pairs perform this stunt with bom leaving the water eventually either singly or attached as a copulating pair. However, these observations I made in late August of aged individuals appeared almost as if they intended to remain here to die. At this latter site on the large lake, I observed two individuals about 15 metres offshore, plunge in and remain fluttering upside down on the surface for up to 15 minutes [...]. Their fluttering frequency diminished to the point where they eventually cooled down and become almost totally motionless." (Author)] Address: Hatchings, G. E-mail: sea-trek@islandnet.com

3978. Hayashi, F.; Dobata, S.; Arai, Y. (2003): Countrywide genetic map of DNA of migratory *Pantala flavescens*. In: Arai, Y. (Ed): A Countrywide Survey of Red Dragonflies. Musashino Satoyama Research Group, Institute of Agriculture and Natural environments. 47 pp. Translation: Ishizawa, N., Tokorozawa City, Japan: 24-32. (in Japanese). [To get information on the population genetics of *P. flavescens* in Japan, the DNA of 33 specimens from Japan, and additional 7 from the Mariana

Islands, Cambodia, and South Korea was analyzed. The primarily results suggest, that the species is highly migratory, and populations of it from oceanic islands far south of Japan toward the Indochina Peninsula have genetic exchanges to each other, as well as those in Japan.] Address: Arai, Y., 1233-2, Oaza Sueno, Yorii-machi, Osato-gun, Saitama Pref., 369-12, Japan.

3982. Hubble, D.S.; Hurst, D. (2003): Management of small dug ponds for Odonata conservation and colonization in an area of valley mire and wet heathland (Bourne Valley, Dorset). *J. Br. Dragonfly Society* 19(1/2): 24-34. (in English). ["Since 1996, and possibly earlier, around 30 small ponds have been dug for nature conservation purposes at a variety of locations within a six hectare area of valley mire and wet heath within the Bourne Valley Local Nature Reserve, Dorset. The site is nationally important for its dragonfly community, supporting 65 per cent of British species of Odonata, and is also noted for its other heathland flora and fauna, including all six British reptile species. To investigate the pattern of colonization over time by Odonata and other aquatic fauna, six ponds were sampled with all Odonata, Trichoptera, Coleoptera and newts (*Triturus*) identified and recorded. Odonata were more abundant and diverse in ponds six or more years old. Coleoptera also increased with age of pond, while Trichoptera decreased. Overall abundance and diversity of aquatic fauna were closely related with the greatest increases within the first three years after pond creation. After this, there was less increase in overall abundance and diversity and changes in community structure were seen. Therefore, to maximize the biodiversity of Odonata and other aquatic invertebrates, a full spectrum of pond ages is required. As some fill and dry, others are newly dug and there is a continual rotating succession of pond habitats. As well as increasing structural diversity within the pond system, more specific aims of heathland pond management are presented which may promote colonization by diverse Odonata populations." 3987. Jödicke, R.; Tol, J. van (2003): Case 3253 - *Libellula aenea* Linnaeus, 1758 (currently *Cordulia aenea*) and *L. flavomaculata* Vander Linden, 1825 (currently *Somatochlora flavomaculata*; Insecta, Odonata): proposed conservation of usage of the specific names by the replacement of the lectotype of *L. aenea* with a newly designated lectotype. *Bulletin of Zoological Nomenclature* 60(4): 272-274. (in English). ["The purpose of this application is to conserve, under Article 74.1 of the Code, the current usage of the names of two dragonfly species. In 1758, Linnaeus established the name *Libellula aenea* for three specimens. These have subsequently been recognized as belonging to two species: *L. aenea* and *L. flavomaculata* Vander Linden, 1825. In 1956, Fraser designated one of Linnaeus's specimens as the lectotype of *L. aenea*. However, the

specimen he designated was the one used by Vander Linden to denote his species *L. flavomaculata*. Fraser's action made *L. aenea* a senior objective synonym of *L. flavomaculata*. It is proposed that one of Linnaeus's specimens other than the one selected by Fraser be designated as the lectotype of *L. aenea*, thus conserving prevailing usage of both names." 3990. Kano, K. (2003): An attempt of interspecific tandem formation with a female of *Planaeschna milnei* (Selys) by a male of *Boyeria maclachlani* (Selys). *Boso no Konchu* No. 31: 5. (in Japanese). ["On September 14, 2003, I saw a female of *P. milnei* ovipositing at a river at Obuta, Chonan-machi, Chosei-gun, Chiba Pref., Japan. It was attacked by a patrolling male of *B. maclachlani*, and fell onto the stream each other. The male struggled to copulate with the female for about 2 minutes, but it did not succeed and flew away. The female was unable to alight from the water and was carried away by the stream. Both species usually differ their habitat each other; in *P. milnei* in upper reaches of a stream and in *B. maclachlani* in the mid stream. My observation spot is a junction of a branch stream and the mid stream of the river, where both habitats might have been connected. I think the male might have mistaken the female for a conspecific female." (Taken from Digest of Japanese Odonatological Short Communications 15; edited and translated by ISHIZAWA, Naoya).] Address: Kano, K., 5-19-17-01, Koishikawa, Bunkyo-ku, Tokyo, 112-0002, Japan

3991. Kano, K. (2003): Copulating flight of a male *Boyeria maclachlani* (Selys) with an inactive female. *Gekkan-Mushi* 394: 25-26. (in Japanese). ["I saw a male *B. maclachlani* attempting copulation on an inactive congener female at the Obuta river at Chonan-machi, Chosei-gun, Chiba Pref., Japan on August 15, 1998. On that day it was fine, and around noon males flew about at the river and approached females for copulation. At 3:00 p.m. I found on the bank an inactive female with its four wings cut at the middle of them, only main

veins left. I picked it up and released it, however, it fell on the ground without fluttering. When put on a rotten log, which is a suitable oviposition substrate, a male appeared after a while took her into tandem formation to fly off. The male attempted to copulate with her, pulling her near him. They fell on to the water, struggling and somehow took tandem formation on the surface of the water. They flew up from the water and perched on a bamboo stem near my observation spot. When I approached it flew up and disappeared." (Taken from Digest of Japanese Odonatological Short Communications 15; edited and translated by ISHIZAWA, Naoya).] Address: Kano, K., 5-19-17-01, Koishikawa, Bunkyo-ku, Tokyo, 112-0002, Japan

- 4005.** Lodge, R.J.; Freeland, J.R. (2003): The use of Odonata museum specimens in questions of molecular evolution. *Odonatologica* 32(4): 375-380. (in English). ["Studies of population genetics and phylogenetics require samples from individuals representing a variety of species and populations. Collecting the necessary individuals may be problematic, particularly for seasonal, rare, or geographically remote organisms. Museum collections therefore provide a potentially valuable resource, and the widespread use of polymerase chain reactions (PCR) means that target regions of DNA can be amplified from very small amounts of tissue. Here modifications to DNA extraction techniques are described that have allowed the authors to extract, amplify, and sequence a portion of mitochondrial DNA from parts of single dragonfly legs taken from museum specimens up to 80 yrs old. It is anticipated that in future these techniques will be applied to a range of odonate studies, including questions of conservation genetics." (Authors)] Address: Freeland, J.R., Dept of Biological Sciences, Open University, Walton Hall, Milton Keynes, MK7 6AA, United Kingdom. E-mail: J.R.Freeland@open.ac.uk

between 1995 and 2002 in the alluvial floodplains of the lower Allier valley as well as in those of some tributaries are presented. The Odonata population of different types of habitats were studied during 10 field trips by observing adults and collecting exuviae at 65 sampling sites. The total number of species observed within the present study amounts 50, at least 40 of them are autochthonous. The study results of the Odonata population are presented for each type of aquatic habitat. The importance of the investigated area for conservation and protection of Odonata and alluvial ecosystems even at European level can be derived - among other things - from the extraordinary richness of the Odonata population. This richness is particularly demonstrated by the Odonata population of the main channel of the river Allier, where 19 autochthonous species were observed, 6 of them belonging to Gomphidae. The author discusses the possibilities of conservation and protection of the lower Allier alluvial floodplains. Finally the results are considered with regard to regeneration measures for other alluvial floodplains in Central Europe." (Author)] Address: Lohr, M., Fachhochschule Lippe und Höxter, Fachgebiete Tierökologie und Landschaftsökologie, An der Wilhelmshöhe 44, D-37671 Höxter, Germany. E-mail: mlohr@fh-hoexter.de

4007. Lucas, B. (2003): Overwintering of larvae of the Common Darter *Sympetrum striolatum* (Charpentier) in the north of England. *J. Br. Dragonfly Society* 19(1/2): 1. (in English). [On 10 December 2001, larvae of *Sympetrum spec.* with only 1.5mm in length were traced. Both *Sympetrum striolatum* and *S. sanguineum* are recorded from the site. "During 2001, both species had an extended flying season in this area, which may account for non-diapause eggs being laid so late in the year. The larval growth of overwintering *S. striolatum* has been recorded at a pond in the New Forest [...]. However, at the same time of year these larvae were twice the size of the Yorkshire ones, i.e. 3mm in length. Research to discover whether such small larvae could withstand a Yorkshire winter was undertaken. I decided to measure the larvae approximately every two weeks. This entailed pond dipping, measuring the larvae at home and then returning them to the pond. On only two occasions did thick ice inhibit access to open water. It was assumed that, as the larvae were only 1.5mm in length when first collected, they were in the second stadium, i.e. the first stadium after the prolarva. As expected, from 10 December 2001 to the end of February 2002, no growth took place. The rate of growth of the larvae until emergence of the adult insect matched that of the New Forest larvae, but was three to four weeks later in the year, this time difference being constant throughout the study. On 13 July 2002, no larvae were found and in fact *S. striolatum* was on the wing. Further visits have been made and exuviae collected. All were *S. striolatum*. Therefore, it seems safe to assume that none of the larvae recorded were *S. sanguineum*." (Author)] Address: Lucas, B., 8 Camborne Drive, Fixby, Huddersfield, West Yorkshire HD2 2NF, UK

4008. Martens, A.; Jödicke, R.; Suhling, F. (2003): An annotated checklist of the Odonata of Namibia. *Cimbebasia* 18: 139-160. (in English). ["This paper presents an annotated checklist of the Odonata of Namibia, which provides information for each recorded species on: World distribution, previous published records, detailed distribution within Namibia and specific notes where appropriate. To date, 102 species of Odonata

have been recorded from Namibia. Additionally, 9 species have been recorded from Botswana and Zambia at stretches of the Chobe/Linyanti and the Zambezi Rivers forming the Namibian borders. These species are also taken into account in the checklist. As many other species are recorded in Angola, in close proximity to the Namibian border further species are to be expected. In addition to the checklist, we further present some general distributional patterns of Namibian Odonata, being: (a) tropical running water species, mainly restricted to the northern or northeastern perennial rivers, (b) tropical species not restricted to running waters, but adapted to more humid environmental conditions, (c) species adapted to arid conditions; being mobile, having opportunistic habitat selection and rapid development, and being widespread in Namibia, (d) species of permanent waters occurring at isolated spots within Namibia, and (e) southern, subtropical species, restricted to the south." (Authors)] Address: Martens, A., Pädagogische Hochschule Karlsruhe, Postfach 111062, D-76060 Karlsruhe, Germany. E-mail: andreas.martens@ph-karlsruhe.de

4009. Martens, A. (2003): Reproductive behaviour of African Odonata - a review. *Cimbebasia* 18: (in English). ["This paper presents a review of the reproductive behaviour of African Odonata, outlines our current knowledge, and further defines priorities for gathering information required to understand biodiversity patterns and evolution of mating systems. To date, information on reproductive behaviour is available for approximately 130 of the 850 species of Odonata known from Africa. A full bibliography of published papers in this field is provided. The aim of this paper is to stimulate systematic collection of previously unpublished observations and to encourage a broader approach to behavioural ecology by including experiences and observations of entomologists who regard themselves as non-specialists in this field. Priorities are defined, with special attention being given to the description and analysis of: (1) reproductive habitats, (2) species-specific behavioural patterns, (3) plasticity of behaviour within a species, (4) the search for behavioural patterns on a higher taxonomic level, and (5) placing behaviour in an ecological context." (Author)] Address: Martens, A., Pädagogische Hochschule Karlsruhe, Postfach 111062, D-76060 Karlsruhe, Germany. E-mail: andreas.martens@ph-karlsruhe.de

4010. Martens, A.; Suhling, F. (2003): The barbed inflorescences of the grass *Setaria verticillata* (L.) Paliot de Beauvois (Poaceae) as a lethal trap for dragonflies (Odonata). *Cimbebasia* 18: 243-246. (in English). ["At a pond below the Von Bach Dam near Okahandja, Namibia, adults of the libellulid anisopteran dragonflies *Crocothemis erythraea* (Brullé) and *Diplacodes lefebvrei* (Rambur) were observed being trapped by flowering stands of *Setaria verticillata* (Poaceae). The spiny seeds of this grass offer a means of seed dispersal by animals. As this species grows beside water, this grass serves fortuitously as a trap for adult dragonflies, especially males, which often use such conspicuous, upright structures as perching sites. Other published accounts of the same phenomenon from throughout the World are summarised." (Authors)] Address: Martens, A., Pädagogische Hochschule Karlsruhe, Postfach 111062, D-76060 Karlsruhe, Germany. E-mail: andreas.martens@ph-karlsruhe.de

- 4011.** Masselot, G.; Nel, A. (2003): Les Odonates sont-ils des taxons bio-indicateurs? *Martinia* 19(1): 7-40. (in French with English summary). ["From a definition of the « biological indicator » concept, which covers very different uses (bio-monitoring, sentinel organisms, bio-informative species), a critical review of the significant contributions using Odonata is carried out. Autochthony of Odonata is discussed. Some synecoparsimony analyses are proposed, which expose a new method to study the relations between Odonata and macrophytes. These tend to show that this relation is not an association, but rather simply a « synecosis », and that many problems do not authorize, in the current state of knowledge, to establish a reliable tool for description of hydrosystems bioassessment, resting on the only conjunction between freshwater macrophytes and Odonates. Complementary studies, including both the whole of the freshwater entomocoenosis for example, and analysis tools that do not introduce neither preliminary scenarisation (ad hoc hypotheses), nor methodological bias, must be undertaken as prerequisites to elaborate a biomonitoring tool for freshwater hydrosystems assessment." - 4021.** Miller, P.; Miller, K. (2003): East African dragonflies. A guide for residents, students and visitors, with colour plates and keys.. *Nature Kenya*, Nairobi. ISBN 9966-9921-3-8: X + 263 pp., 8 col. pls incl. (in English). [Peter Miller, outstanding odonatologist of the past century and teacher for many of us, together with his wife Kate spent a significant time of his life studying African Odonata. He planned to intensify these studies and to write a book on African dragonflies, but was sadly no more in the situation to finish it. On the basis of his and their common ideas, Kate Miller prepared a book in the memorial of Peter. The book intends "to aid appreciation and conservation of dragonflies of East Africa. It

was written for School and University students and other residents in Kenya, Tanzania and Uganda, and also for visitors". Unique in its scope, it provides all the basic information required by a student of African odonate ecology, biology and behaviour, including a checklist of East African species, a key to the families and genera, and a very informative glossary. 30 selected species are introduced in a monographic way. Each species is depicted by a colour photo, and morphological characters are outlined. Much hitherto unpublished information by the authors is provided. The didactical concept of this book is unique and an authoritative example for introduction into the study of Odonata or any other group of insects. It should not be missing from any odonatological library. The following species have been selected for presentation: *Phaon iridipennis*, *Umma saphirina*, *Lestes virgatum*, *Chlorocypha trifaria*, *Platycypha caligata*, *Pseudagrion melanicterum*, *P. hageni*, *Mesocnemis singularis*, *Platycnemis congolensis*, *Chlorocnemis marshalli*, *C. pauli*, *Elatoneura glauca*, *Ictinogomphus ferox*, *Notogomphus leroyi*, *Paragomphus genei*, *Aeshna ellioti*, *Anax imperator*, *Gynacantha bullata*, *Phyllomacromia funicularia*, *P. nyanzana*, *Brachythemis lacustris*, *B. leucosticta*, *Crocothemis erythraea*, *Hadrothemis coacta*, *Orthetrum trinacria*, *Palpopleura lucia*, *Pantala flavescens*, *Rhyothemis notata*, *Tetrathemis polleni*, and *Tholymis tillarga*.] Order: Price £ 20.- net.: Prepaid orders to be sent to: Mrs A.K. Miller, 68 Blenheim Dr., Oxford, OX2 8DQ, UK

4022. Misof, B.; Fleck, G. (2003): Comparative analysis of mt LSU rRNA secondary structures of Odonates: structural variability and phylogenetic signal. *Insect Molecular Biology* 12(6): 535-548. (in English). ["Secondary structures of the most conserved part of the mt 16S rRNA gene, domains IV and V, have been recently analysed in a comparative study. However, full secondary structures of the mt LSU rRNA molecule are published for only a few insect species. The present study presents full secondary structures of domains I, II, IV and V of Odonates and one representative of mayflies, *Ephemera* sp. The reconstructions are based on a comparative approach and minimal consensus structures derived from sequence alignments. The inferred structures exhibit remarkable similarities to the published *Drosophila melanogaster* model, which increases confidence in these structures. Structural variance within Odonates is homoplastic, and neighbour-joining trees based on tree edit distances do not correspond to any of the phylogenetically expected patterns. However, despite homoplastic quantitative structural variation, many similarities between Odonates and *Ephemera* sp. suggest promising character sets for higher order insect systematics that merit further investigations." (Authors)] Address: Misof, B., Dept of Entomology, Researchinstitute Alexander König and Museum of Zoology, Adenauerallee 160, D-53113 Bonn, Germany. E-mail: b.misof@uni-bonn.de

4024. Moore, N.W. (2003): Four long term studies on dragonfly populations. *J. Br. Dragonfly Society* 19(1/2): 2-7. (in English). [Few long term studies on dragonfly populations have been published anywhere in the world. The author summarizes those four that have been undertaken since 1949. "1. A small canalized river (the Portbury River) in the Gordano valley, Avon (previously Somerset), 1949-1952. General studies on the behaviour and ecology of dragonflies and development of the transect technique. In these studies quantitative observations were confined to Anisoptera. References: Moore (1953a, 1953b) 2. Water-filled bomb craters, Arne Heath, Dorset, 1954-1960. Studies on dragonfly behaviour, notably on highest steady density. Reference: Moore (1964) 3. Experimental ponds, Woodwalton Fen National Nature Reserve Cambridgeshire (previously Huntingdonshire). Intensive observations 1962-1988, less intensive 1989 onwards. Studies on changes in populations due to serai development and management of the ponds, and on territorial behaviour. References: Moore (1991, 1995, 2001) 4. Large pond in small private nature reserve, Swavesey, Cambridgeshire. 1984 onwards. Studies on population changes due to habitat development and on the origins of the fauna, on territorial behaviour, and on the behaviour of immature insects. References: Moore (2000, 2001, 2002a,b)." All these sites were revisited during the years after starting the intensive studies. Major changes are briefly discussed.] Address: Moore N.W., The Farmhouse, 117 Boxworth End, Swavesey, Cambridge CB4 5RA, UK

4027. Muzlanov, Yu.A. (2003): The pattern of distribution of defects of wing venation in the banded agrion (*Calopteryx splendens*). *Ontogenez* 34(1): 61-66. (in Russian with English summary). [The distribution of morphological structures was studied in wings of the banded agrion (*Calopteryx splendens* Harr.) from different intrapopulation groups. Dragon flies of odd years of emergence are characterized by a more stable pattern of ontogenetic processes according to the mean total

number of venation defects. The sharply increased level of radiation in summer 1986, which coincided with the flight of dragon-flies, could have caused hereditary defects expressed in a sequence of generations of even years of emergence. Apparently, most alternative features of wing venation in dragon-flies can be considered as markers of stability of the ontogenetic processes, which reflect, to a great extent, genotypic features of the organisms in a population. A possible mechanism has been described, which explains the proposed topological model of formation of the venation defects of different types. The increase in mean frequencies of defects can suggest an enhanced development over the aberrant epigenetic trajectories, which may lead to the elimination of these organisms under the influence of various agents, i.e., to the stabilizing selection in a population. The results obtained suggest that defects of venation arise on the stochastic basis and their frequency increases upon destabilization of ontogenetic processes not only by the environmental factors, but also by genetic stress. Venation defects can be successfully used in population biomonitoring." (Author)] Address: Muzlanov, Yu.A., Zarevskii Secondary School, Zarya, Mikhailovskii Raion, Ryazan Oblast, 391728, Russia

4028. Nachtigall, W. (2003): 'Aufflug, mit dem Widerstand' bei der Blauflügel-Prachtlibelle *Calopteryx virgo* (Odonata: Calopterygidae). *Entomologia Generalis* 26(4): 241-251. (in German with English summary). [It is shown that - contrary to equal phasic up to antiphase beating of the fore- and hindwings at normal flight and in mating flight (a.o. ANDERS & RÜPPELE 1996) - during quick vertical starts, all wings beat rapidly and synchronously downward. Model measurements using flow visualisation show that hereby a downward travelling vortex ring, very similar to that of a white cabbage butterfly's vertical take-off (ELLINGTON 1980), is generated. When parameters are measurable, calculations using approximation parameters show that an upward directed reaction force corresponding up to double body weight is generated, thus catapulting the insect vertically into the air. The very next wing-beat already shows a pronounced phase shift which permits lift generation. Thereby the possibility of flying by drag generation, that was indicated by RÜPPELE (1985, 1989) but not analysed in terms of flow mechanics was proved using a flight situation that was measurable and the parameters of which could be calculated." (Author)] Address: Nachtigall, W., Allgemeine Biologie, Universität des Saarlandes, D-66041, Saarbrücken, Germany

4029. Nagasaka, T.; Motobayashi, T.; Nakagawa, M. (2003): Relation of the rice planting period to the quantity of occurrence of *Sympetrum frequens*. In: Arai, Y. (Ed): A Countrywide Survey of Red Dragonflies. Musashino Satoyama Research Group, Institute of Agriculture and Natural environments. 47 pp. Translation: Ishizawa, N., Tokorozawa City, Japan: 33-37. (in Japanese). [The effects of temporal drainage, irrigation, and harvest of rice plants on *S. frequens* in the paddy fields of the Field Museum Honcho, Field Science Center, University of Agriculture and Technology, Tokyo, Japan are described.] Address: Nagasaka, T., Faculty of Agriculture, Tokyo University of Agriculture and Technology, Japan

4039. Payne, J.C. (2003): Dispersal and dynamics of dragonfly communities in a lake network. Dissertation, Dept Biol., University of Washington: 146 pp. (in English). [In a network of desert lakes in eastern Washington State, USA, the population dynamics of dragonflies was studied. The dissertation comprises of four main chapters: "I. DRAGONFLY POPULATION DYNAMICS AT A LANDSCAPE SCALE: I studied the temporal and spatial variability in dragonfly populations [...], and investigated the causes of the variability. The simultaneous trapping of 25 lakes allowed temporal and spatial trends to be investigated. Four lakes were trapped in the 1960s and again in the 1990s, and an additional 21 lakes were simultaneously trapped in the late 1990s. I found that although the species pool was relatively stable over a 30-year period, the abundance of dragonflies varied greatly between lakes, years and species. Populations of rare species were more variable than common species. Predatory fish such as bass and carp had a strong negative impact on most dragonfly species but rainbow trout, which are stocked in

study area lakes, did not, perhaps because they do not reach high densities. Application of the toxin rotenone to lakes for the purpose of killing unwanted fish appeared to allow the recovery of some dragonfly species. Lastly, I argue that the scale of most dragonfly studies appears to be too small to answer questions about population dynamics.

II. USE OF AN ELEMENTAL MARKER, RUBIDIUM, TO STUDY DISPERSAL OF AQUATIC INSECTS (see OAS 3881 in this issue).

III. MEASURING THE RATIO OF IMMIGRANT TO RESIDENT BREEDERS IN A DRAGONFLY POPULATION: In a patchy landscape, the persistence of a metapopulation of animals or plants depends on the exchange of individuals between sub-populations via dispersal. However, not all populations in patchy landscapes are metapopulations; in some cases demographic or environmental forces are more important than the degree of connectivity between sub-populations. Unfortunately, it is difficult to estimate dispersal rates or to estimate the impact of dispersers, particularly for populations of small animals that cannot be easily marked, have high mortality in early life, and may be very mobile. This experiment was designed to measure the relative contribution of residents versus immigrants to reproduction in a dragonfly population in a highly dynamic, patchy landscape. I marked all of the resident larval dragonflies in a lake with an internal chemical marker, rubidium, that persists through emergence (i.e. between larval and adult life stages). Subsequently I collected breeding dragonflies at the marked lake and at several other lakes close by to investigate the relative exchange rates of breeding adults. The proportion of dragonflies that were residents was surprisingly low: only 9.8 % (61 out of 619) adult dragonflies captured at the pond were marked. A sample of 747 adults from 3 neighboring lakes within 3.2 km of the marked lake captured only four marked dragonflies, all at a lake less than 100 meters away. There were significant differences between taxonomic families: 30-60% of the breeding dragonflies of the family Libellulidae were residents, whereas fewer than 10% of the smaller Coenagrionidae and the larger Aeshnidae were residents. There were also differences between the sexes: there were fewer resident males than females in every species where I caught marked individuals, suggesting that dispersal rates of males are greater than dispersal rates of females. The design of the experiment did not allow me to distinguish between several possible interpretations, including that many of the native dragonflies may have dispersed.

III. MEASURING THE RATIO OF IMMIGRANT TO RESIDENT BREEDERS IN A DRAGONFLY POPULATION Abstract In a patchy landscape, the persistence of a metapopulation of animals or plants depends on the exchange of individuals between sub-populations via dispersal. However, not all populations in patchy landscapes are metapopulations; in some cases demographic or environmental forces are more important than the degree of connectivity between sub-populations. Unfortunately, it is difficult to estimate dispersal rates or to estimate the impact of dispersers, particularly for populations of small animals that cannot be easily marked, have high mortality in early life, and may be very mobile. This experiment was designed to measure the relative contribution of residents versus immigrants to reproduction in a dragonfly population in a highly dynamic, patchy landscape. I marked all of the resident larval dragonflies in a lake with an internal chemical marker, rubidium, that persists through emergence (i.e. between larval and adult life stages). Sub-

sequently I collected breeding dragonflies at the marked lake and at several other lakes close by to investigate the relative exchange rates of breeding adults. The proportion of dragonflies that were residents was surprisingly low: only 9.8 % (61 out of 619) adult dragonflies captured at the pond were marked. A sample of 747 adults from 3 neighboring lakes within 3.2 km of the marked lake captured only four marked dragonflies, all at a lake less than 100 meters away. There were significant differences between taxonomic families: 30-60% of the breeding dragonflies of the family Libellulidae were residents, whereas fewer than 10% of the smaller Coenagrionidae and the larger Aeshnidae were residents. There were also differences between the sexes: there were fewer resident males than females in every species where I caught marked individuals, suggesting that dispersal rates of males are greater than dispersal rates of females. The design of the experiment did not allow me to distinguish between several possible interpretations, including that many of the native dragonflies may have dispersed to breed elsewhere or died after emergence, or a large number of immigrants may have come in to breed. Nevertheless, it appears that immigration is very important to the population dynamics of dragonflies in some ponds, suggesting that some dragonfly communities may be characterized by metapopulation dynamics.

IV. THE INTERACTION OF STOCHASTIC DISPERSAL EVENTS WITH FOOD WEB DYNAMICS DURING THE FORMATION OF NEW DRAGONFLY COMMUNITIES: Metapopulation theory highlights the importance of organism movement and rare colonization events to population dynamics and community structure. However, the theory is simplistic in its treatment of species interactions, and evidence for the importance of metapopulation dynamics in nature is mixed. Furthermore, a large number of experiments have shown that inter-species interactions, particularly predation, can outweigh other factors in determining population dynamics and community composition. This experiment was an attempt to weigh the relative importance of dispersal dynamics versus food web interactions in determining the species composition of new communities. I created a set of widely-separated artificial ponds in a natural landscape inhabited by 20 species of dragonflies, and manipulated predation rates and dispersal distances to evaluate their influence on colonization success by dragonflies of different sizes. The body size of a predator can be a predictor of 1) its trophic level in a food web and 2) the scale of its movement in a landscape. Dragonflies of 3 taxonomic families colonized the ponds and there were differences between the families in their propensity to colonize isolated ponds. I found that the effects of predation dominated the community composition once dragonflies had arrived in the new habitat, and the identity of the top predator was important. However, the outcome of competition between large and medium-sized dragonflies depended on order of arrival (a so-called "priority effect"). Mid-sized species were particularly susceptible to predation. They gained an advantage by arriving first, and appeared to follow a strategy that increased the probability of discovering isolated ponds before potential predators did. In short, the species composition of new communities was determined by food web dynamics, but the strength and direction of some food web interactions depended on the timing of stochastic dispersal events whose probability was determined by the spatial layout of a pond and the dispersal behavior of the species involved." 4049. Poulton, B.C.; Wildhaber, M.L.; Charbonneau, C.S.; Fairchild, J.F.; Mueller, B.G.; Schmitt, C.J. (2003): A longitudinal assessment of the aquatic macroinvertebrate community in the channelized lower Missouri River. *Environmental Monitoring & Assessment* 85(1): 23-53. (in English). ["We conducted an aquatic macroinvertebrate assessment in the channelized reach of the lower Missouri River, and used statistical analysis of individual metrics and multimetric scores to identify community response patterns and evaluate relative biological condition. We examined longitudinal site differences that are potentially associated with water quality related factors originating from the Kansas City metropolitan area, using data from coarse rock substrate in flowing water habitats (outside river bends), and depositional mud substrate in slack water habitats (dike fields). Three sites above river mile (RM) 369 in Kansas City (Nebraska City, RM=560; St. Joseph, RM=530; Parkville, RM=377) and three below (Lexington, RM=319; Glasgow, RM=228; Hermann, RM=94) were sampled with rock basket artificial substrates, a qualitative kicknet method, and the Petite Ponar. We also compared the performance of the methods used. A total of 132 aquatic macroinvertebrate taxa were collected from the lower Missouri River; one third of these taxa belonged to the sensitive EPOT insect orders (Ephemeroptera, Plecoptera, Odonata, and Trichoptera). Rock baskets had the highest mean efficiency (34.1%) of the methods, and the largest number of taxa was collected by Ponar (n=69) and kicknet (n=69) methods. Seven of the 15 metrics calculated from rock basket data, and five of the nine metrics calculated from Ponar data showed highly significant differences (ANOVA, P<0.001) at one or more sites below Kansas City. We observed a substantial reduction in net-spinning Trichoptera in rock habitats below Kansas City (Lexington), an increase in relative dominance of Oligochaeta in depositional habitats at the next site downstream (Glasgow), and lower relative condition scores in rock habitat at Lexington and depositional habitat at Glasgow. Collectively, these data indicate that some urban-related impacts on the aquatic macroinvertebrate community are occurring. Our results suggest that the methods and assessment

framework we used in this study could be successfully applied on a larger scale with concurrent water and sediment chemistry to validate metrics, establish impairment levels, and develop a specific macroinvertebrate community index for the lower Missouri River. We recommend accomplishing this with longitudinal multi-habitat sampling at a larger number of sites related to all potential s of impairment, including major tributaries, urban areas, and points." 4050. Raab, R. (2003): Die Besiedlung neu geschaffener Uferstrukturen im Staubereich Freudenau (Wien, Niederösterreich) durch Libellen (Insecta, Odonata). *Denisia* 10: 79-99. (in German with English summary). [" From 1998 to 2001 the dragonfly fauna at nine new study sites along the restructured Danube shoreline as well as at the Tritonwasser on the Danube Island were observed in the course of 81 field trips. In all 14130 individuals and 29 species of dragonflies respectively were found at the nine new sites. Most frequent was *Ischnura elegans* with 55% of all individuals followed by *Platycnemis pennipes* with 20%. In the whole period from 1990 to 2001 39 species were observed at the Tritonwasser. In 2000 and 2001 *Leucorrhinia pectoralis* one of Europeans most threatened dragonfly species and listed in the Annex II of the Habitats Directive was found in a small autochthonous population at the Kreimellacke. With the results of the dragonfly fauna, the whole Danube Island is classified a good ecological status. Considering only the nine new sites, the ecological status would be moderate because of the relatively small number of autochthonous and sensitive autochthonous species as well as the small range of the Odonate Habitat Index (OHI). The straight structureless shoreline of the Danube is of no use for the dragonflies. The fourth year of investigation clearly showed that not only pools but also side channels and coves could be of importance for many dragonfly species if constructed right. The restructure measurements on the shoreline of the Danube Island are not sufficient enough to support a good corridor function of the Danube Island for dragonflies. Additional constructions of larger pools, for example the planned Phönixteich in the northern part of the Danube Island, are necessary to provide long-term suitable habitats also for highly threatened dragonfly species and also to improve the corridor function of the Danube Island." June 2003, at Westhay Moor Reserve, Somerset, UK I observed a mature male *C. puella* fly towards a male *P. icarus*, which was flying low over a grassy patch adjoining a reed-bed by a lake. The damselfly flew repeatedly at the butterfly, buffeting it at times, and so preventing it from settling. This aggressive behaviour, which occurred during a brief sunny spell, continued for one minute, after which the butterfly flew off. Male *C. puella* were numerous in the area at the time (several were in either the ring or tandem position) but, apart from the one individual, they all disregarded the Common Blue Butterfly." Possible reasons of this behaviour are discussed. It is believed that "the visual impact of the butterfly's relatively large blue wing expanse could have triggered sexual attraction."] Address: Radford, P., Crossways Cottage, West Bagborough, Taunton, Somerset TA4 3EG, UK

4056. Rehn, A.C. (2003): Phylogenetic analysis of higher-level relationships of Odonata. *Systematic Entomology* 28(2): 181-240. (in English). ["This is the most comprehensive analysis of higher-level relationships in Odonata conducted thus far. The analysis was based on a detailed study of the skeletal morphology and wing venation of adults, complemented with a few larval characters, resulting in 122 phylogenetically informative characters. Eighty-five genera from forty-five currently recognized families and subfamilies were examined. In most cases, several species were chosen to serve as exemplars for a given genus. The seven fossil outgroup taxa included were exemplar genera from five successively more distant odonatoid orders and suborders: Tarsophlebiidae (the closest sister group of Odonata, previously placed as a family within 'Anisozygoptera'), Archizygoptera, Protanisoptera, Protodonata and Geroptera. Parsimony analysis of the data, in which characters were treated both under equal weights and implied weighting, produced cladograms that were highly congruent, and in spite of considerable homoplasy in the odonate data, many groupings in the most parsimonious cladograms were well supported in all analyses, as indicated by Bremer support. The analyses supported the monophyly of both Anisoptera and Zygoptera, contrary to the well known hypothesis of zygopteran paraphyly. Within Zygoptera, two large sister clades were indicated, one comprised of the classical (Selysian) Calopterygoidea, except that Amphipterygidae, which have traditionally been placed as a calopterygoid family, nested within the other large zygopteran clade comprised of Eraser's 'Lestinoidea' plus 'Coenagrionoidea'

(both of which were shown to be paraphyletic as currently defined). *Philoganga* alone appeared as the sister group to the rest of the Zygoptera in unweighted cladograms, whereas *Philoganga* + *Diphlebia* comprised the sister group to the remaining Zygoptera in all weighted cladograms. 'Anisozygoptera' was confirmed as a paraphyletic assemblage that forms a 'grade' towards the true Anisoptera, with *Epiophlebia* as the most basal taxon. Within Anisoptera, *Petaluridae* appeared as the sister group to other dragonflies." (Author)] Address: Rehn, A.C., 2817 G Street Apartment 1, Sacramento, California 95816, USA

4060. Rowell, K.; Blinn, D.W. (2003): Herbivory on a chemically defended plant as a predation deterrent in *Hyalella azteca*. *Freshwater Biology* 48(2): 247-254. (in English). ["1. We investigated whether a population of the freshwater amphipod, *Hyalella azteca*, which consumed plants with defensive secondary compounds, reduced predation as reported for terrestrial and marine systems. 2. Field observations in Montezuma Well, U.S.A., indicated a strong association between the emergent macrophyte, *Berula erecta* and *H. azteca*. We hypothesised that this geographically isolated population of sedentary amphipods was able to consume roots of the chemically defended *B. erecta* as a deterrent against predation. *Berula erecta* is in the family Api-

aceae, which commonly produce coumarins that deter herbivory in terrestrial systems. 3. *Hyalella azteca* consumed roots of *B. erecta* at a significantly greater rate than alternative macrophyte substrata in Montezuma Well. Additionally, *H. azteca* moulted at a significantly higher rate when consuming *B. erecta* compared with a diet of periphyton. 4. Two insect predators (*Telebasis salva* and *Belostoma bakeri*) with different feeding strategies were used to assess the effects of a *B. erecta* diet on predation rates in the laboratory and in Montezuma Well. *Hyalella azteca* was preyed on at a significantly lower rate by both predators when given a strict diet of *B. erecta* roots compared with a diet of periphyton. 5. This is the first experimental evidence that predation on a freshwater herbivore, *H. azteca*, was reduced when it consumed a chemically defended plant." 4063. Sauseng, M.; Pabst, M.-A.; Kral, K. (2003): The dragonfly *Libellula quadrimaculata* (Odonata: Libellulidae) makes optimal use of the dorsal fovea of the compound eyes during perching. *Eur. J. Entomol.* 100: 475-479. (in English). ["We studied visual orientation and perching behaviour of a territorial libellulid dragonfly species, *L. quadrimaculata*. The studies were performed during sunny, cloudless conditions at a pond in southern Styria, Austria, from May to July of 2001 and 2002. Individual males were observed for periods of 3 to 4 weeks. We measured dragonfly's horizontal orientation relative to the solar azimuth, and vertical orientation relative to the solar altitude. The measurements indicated that the males had a favourable view of the sky during perching. In addition, the relative amounts of ultraviolet (UV) and blue-violet radiation in scattered light (not direct sunlight) were calculated for the whole sky and for the section of the sky viewed by the fovea. Our results show that the dorsal fovea is directed preferentially toward a section of the sky away from the sun, with less radiation but a higher UV and blue-violet saturation. The present findings fit in well with the hypothesis, based on optical and physiological data, that the fovea, which is sensitive only to blue and UV radiation, is

optimally suited to the detection of small, rapidly flying insects against the blue sky. The findings supply the first behavioural correlates of this foveal specialisation." 4067. Schindler, M.; Fesl, C.; Chovanec, A. (2003): Dragonfly associations (Insecta: Odonata) in relation to habitat variables: a multivariate approach. *Hydrobiologia* 497: 169-180. (in English). ["In a dragonfly survey, carried out in a lowland wetland area in eastern Austria, a total of 19 resident species was recorded. Multivariate statistical procedures were used to analyse the relationship between dragonfly assemblage patterns and environmental variables. Besides widespread and euryoecious species with unspecific habitat requirements two dragonfly associations were identified: on the one hand species mainly occurring at temporary natural and near-natural ponds characterised by rush and reed vegetation, on the other hand species preferring permanent waters such as the artificial waterbodies in the investigation area characterised by floating macrophytes. Water persistence and the existence of floating macrophytes determined the formation of species assemblages." 4068. Schultz, H.; Waringer, J.A.; Chovanec, A. (2003): Assessment of the ecological status of Danubian floodplains at Tulln (Lower Austria) based on the Odonata Habitat Index (OHI). *Odonatologica* 32(4): 355-370. (in English). ["The ecological status of waterbodies situated in a Danubian floodplain section at Tulln (Lower Austria) was assessed by a dragonfly survey using the OHI approach suggested by CHOVANEC & WARINGER (2001, Regulated Riv. Res. Management 17: 493-507). The investigation was carried out at 28 standing water bodies and 2 reference sites situated directly at the Danube. Stretches of 100 m shorelength

were mapped and the "Representative Spectrum of Odonata Species" (SCHMIDT, 1985, *Odonatologica* 14: 127-133) was recorded. Only autochthonous species were used for the assessment procedure. A total of 11 Zygoptera and 20 Anisoptera species was recorded, 29 of them autochthonous. Site-specific Odonata Habitat Indices ranged from 1.72 to 3.67. The OHI of the only reference site where Odonata were detected directly at the Danube was 1.38. The mean OHI for the whole floodplain section was 2.79. These figures indicate a relatively high level of habitat diversity. By comparing this status quo with reference conditions derived from the overall habitat situation before the regulation and from old species inventories dating back to the 19th century, the status of the Tulln floodplain section was ranked as class II ("good ecological status") in a 5-tiered classification scheme." 4074. Smith, G.R.; Vaala, D.A.; Dingfelder, H.A. (2003): Distribution and abundance of macroinvertebrates within two temporary ponds. *Hydrobiologia* 497: 161-167. (in English). ["We investigated the distributions of macroinvertebrates within two temporary ponds (Spring Peeper Pond and Taylor-Ochs Pond) in central Ohio and examined what environmental factors may be driving those distributions. We sampled macroinvertebrates in Spring Peeper Pond three times from May to July 2001, and Taylor-Ochs Pond two times from May to June 2001. Macroinvertebrate distributions were significantly aggregated on all sampling dates in both ponds. Bivalve abundance in Spring Peeper Pond was higher in shallower water. The distribution of bivalves in Taylor-Ochs Pond was not correlated with any variable we measured. Dragonfly nymph abundance in Taylor-Ochs Pond decreased between the first and second sampling dates, whereas in Spring Peeper Pond no factor examined was correlated with dragonfly nymph density. Snail densities in Spring Peeper Pond were negatively related to dissolved oxygen and depth. In Taylor-Ochs Pond, snail abundance was positively related to temperature. The densities of damselfly nymphs in Spring Peeper Pond were positively related to dissolved oxygen and depth and declined across the study. In Spring Peeper Pond, hemipteran densities were negatively related to depth and increased across the study. Damselfly nymphs and hemipterans were not common enough in Taylor-Ochs to analyze. In general, the abiotic and biotic factors we examined explained relatively little (<37% in all cases) of the within pond distribution of the macroinvertebrates in our two study ponds." (Authors) Address: Smith, G.R., Department of Biology, Denison University, Granville, OH 43023 USA. E-mail: smithg@denison.edu

4075. Sparmberg, H.; Bößneck, U. (2003): Die Schutzgebiete der Landeshauptstadt Erfurt (Thüringen) Teil IX: Flora und Fauna des GLB "Feuchtwiese Schwansee". 4077. Stewart, T.W.; Shumaker, T.L.; Radzio, T.A. (2003): Linear and nonlinear effects of habitat structure on composition and abundance in the macroinvertebrate community of a large river. *American Midland Naturalist* 149(2): 293-305. (in English). ["We used an experiment and regression analyses to quantify effects of spatial variation in habitat structure abundance on a riverine macroinvertebrate community under winter conditions. Concrete slabs (0.21 m²; n=24) with different numbers of stones (mean individual stone surface area=6.44 cm²) attached to upper faces were placed in the James River and retrieved after 28 d. Macroinvertebrate abundance and taxonomic richness on slabs were significantly positively related to stone abundance. Total macroinvertebrate abundance and abundance of oligochaetes (*Nais* spp.), Asiatic clams (*Corbicula fluminea*), caddisflies (*Leptoceridae*), riffle beetles (*Elmidae*) and stoneflies (*Strophopteryx* sp.) were linearly related to stone abundance. However, nonlinear relationships occurred between stone abundance and macroinvertebrate taxonomic richness and between stone abundance and abundance of dragonflies (*Erpetogomphus* sp.), caddisflies (*Hydropsychidae*), chironomids (*Eukiefferiella* spp.), mayflies (*Ephemerelellidae*) and stoneflies (*Taeniopteryx* sp.). Nonlinear relationships were usually characterized by dramatic increases in macroinvertebrate abundance and taxonomic richness across a gradient of increasing stone abundance when abundance was low (0-43 stones/0.08 m² slab face; 0-40% of slab face covered by stones), but weak responses to additional stones at higher stone abundance (84-160 stones / 0.08 m²; 89-96% cover). These nonlinear relationships reflected similar nonlinear relationships between abundance of stones and particulate matter. We conclude that small quantities of habitat structure have significant positive effects on macroinvertebrate abundance and diversity in the James River during winter. At a local scale, habitat structure promotes macroinvertebrate colonization and retention by increasing habitat diversity. Stones and similar physical objects also indirectly benefit macroinvertebrates by trapping particulate matter that provides animals with food and additional habitat." (Authors)] Address: Stewart, T.W., Department of Natural Sciences, Longwood University, Farmville, VA, 23909, USA

4078. Stoks, R.; McPeck, M.A. (2003): Antipredator behavior and physiology determine *Lestes* species turnover along the pond-permanence gradient. *Ecology* 84(12): 3327-3338. (in English). ["Identifying key traits that shape trade-offs that restrict species to only a subset of environmental gradients is crucial to understanding and predicting species turnover. Previous field experiments have shown that larvae of *Lestes* damselfly species segregate along the entire gradient of pond permanence and predator presence and that differential predation risk and life history constraints together shape their distribution. Here, we report laboratory experiments that identify key differences in behavior and physiology among species that structure their distributions along this gradient. The absence of adaptive antipredator behavioral responses against large dragonfly larvae and fish of *Lestes* dryas, the only species to inhabit predator-free vernal ponds that dry each year, is consistent with its high vulnerability to predation and probably the key trait that excludes it from parts of the gra-

dient with predators. The reciprocal dominance of two other *Lestes* species in permanent waters dominated by either dragonflies or fish can be explained by the lack of effective antipredator behaviors against dragonflies and fish, respectively. Maximal growth rates did not differ among *Lestes* along the gradient. However, in the natural predator environment of vernal ponds (only conspecific cannibals), the vernal-pond *Lestes* had higher growth rates than the other *Lestes* suggesting that this excludes other *Lestes* from vernal ponds. Similarly, *Lestes* species that inhabit temporary ponds (i.e., ponds that dry intermittently every few years but not every year) had a higher growth rate than the fishless permanent-pond *Lestes* in the presence of the syntopic dragonfly predator. These growth differences among *Lestes* in predator treatments were not due to differences in food intake, but due to differences in physiology. The vernal-pond *Lestes* converted more assimilated food into body mass compared to the other *Lestes* in the presence of conspecific larvae, and the temporary-pond *Lestes* had a higher conversion efficiency than the fishless permanent-pond *Lestes* in the presence of the syntopic dragonfly predators. In contrast, reductions in growth rate within species in the presence of syntopic predators were both physiologically and behaviorally mediated. The interplay between behavior and physiology may be a common feature of the growth/predation-risk trade-off, and their joint study is therefore critical to mechanistically link phenotype, performance, and community assembly along the freshwater habitat gradient." (Authors)] Address: McPeck, M., Dept Biol. Sci., Dartmouth College, Hanover, New Hampshire 03755, USA. E-mail: mark.mcpeek@dartmouth.edu

4079. Suhling, F.; Jödicke, R.; Schneider, W. (2003): Odonata of African arid regions - are there desert species? *Cimbebasia* 18: 207-224. (in English) ["This paper reviews current knowledge of desert-inhabiting Odonata in Africa. By comparing literature data of countrywide and some regional African Odonata surveys we identify typical desert dragonflies and analyse traits enabling them to survive in desert conditions. Two criteria are used in order to differentiate such species, viz. endemism in deserts and widespread occurrence in desert areas. Very few endemics occur in the Sahara, Arabian and Somalian Deserts of Africa, almost all occurring in permanent waters. In southern African arid regions no desert endemics are known, and most of the widespread desert-dwelling species do not appear to be restricted to deserts, their main habitats being in savanna wetlands. All are shown to be common over most of the Afrotropical and/or southern Palaearctic Regions. In contrast to most endemics, widespread species colonise a broad spectrum of aquatic habitats, including ephemeral waterbodies. Some traits allow Odonata to exist in deserts. Typically desert species are highly mobile and multivoltine, i.e. they have up to four or five, sometimes overlapping, annual generations, allowing them to develop in temporary wetlands. Many species are opportunistic with respect to the type of aquatic habitat they colonise. A cluster analysis on presence/absence data for 529 dragonfly species reveals that, among dragonfly assemblages in deserts, most are similar to each other, but differ from those in non-desert regions in Africa. Thus, it is concluded that there are typical dragonfly assemblages of desert wetlands that are similar in the African and the Arabian Deserts. Based on research, Odonata assemblages of some typical wetlands in the Sahara and Namib De-

serts are described." (Authors)] Address: Suhling F., Inst. Geoökologie, TU Braunschweig, Langer Kamp 19c, D-38102 Braunschweig, Germany. E-mail: f.suhling@tu-bs.de

4084. Theischinger, G. (2003): Coerrections to "Dragonflies of Victoria" by G. Theischinger and J.H. Hawking. *Austrolestes* 8: 4. (in English). [A few corrections are listed.] Address: Theischinger G., 2A Hammerley Road, Grays Point, NSW 2232, Australia

4085. Theischinger, G.; Hawking, J.H. (2003): *Dragonflies of Victoria: an identification guide to adult and larval dragonflies (Odonata)*. *Coop. Res. Cent. Freshw. Ecol.*, Albury/NSW. ISBN 1-876144-49-1: iv+65 pp. (in English). ["An identification guide, designed for non-professional and professional entomologists. The dichotomous keys are accompanied by figs of diagnostic characters, to aid the identification of both adults and larvae known to occur in Victoria, Australia (76 species). Colour photographs of most species are also provided." For an extensive review see the following *Verbatim* from *Austrolestes* 7: Orr, B. (2003): "Dragonflies of Victoria is a slim A5 (21x15cm) volume of 64 pages, soft-bound and produced to a high standard on glossy paper. It is easily carried into the field, just fitting into the more capacious map pockets found on cargo trousers, but is best protected by a plastic bag if treated in this way. Following an introductory section including a checklist of Latin and vernacular names and a very compact but exceptionally clear illustrated guide to a-

dult and larval morphology, the book is essentially a collection of illustrated keys to suborders, families and the 80 species of Odonata recorded from Victoria and neighbouring regions of southern NSW. Separate keys cover both adults and larvae. The adults, mostly living, of nearly all species and the living larvae of over fifty species are illustrated by 136 thumbnail photographs. The dichotomous keys are exceptionally user-friendly. The language is simple and direct. Most key couplets are accompanied by identically labelled diagrams placed immediately to the right of the text. Photo references are provided for each species. A large number of the adult diagrams are taken from Watson et al, 1991, 'The Australian Dragonflies' and the new adult diagrams are after the same style. Larval diagrams are also clear and accurate. The photographs are of mixed quality, but at least give the reader a good idea of the general appearance of each species. For the novice especially they provide an invaluable confidence-building boost when using the keys, for no matter how well constructed, all dichotomous keys suffer from the problem that one false answer can lead the user well astray. For the dragonfly watcher, as opposed to the collector with a specimen in the hand, it would be beneficial if size ranges and habitat preferences were also given for each species. To readers not familiar with other recent works of these authors the higher classification used in the checklist may be confusing. Four family names, the Telephlebitidae, Austrocorduliidae, Cordulephyidae and Hemicorduliidae are not to be found in Jill Silsby's widely read 'Dragonflies of the World'. These are used without justification or explanation of how they relate to better-known schemes. Although I do not dispute the validity of these groupings, it is debatable if novel family-group names should be introduced in a key intended for popular use. The vernacular English names suggested in the checklist may not be to everyone's taste. However they are presented unobtrusively and may at least provide inspiration for those who see the need for such names. This list is, after all, neither authorized nor immutable and anyone wishing to dabble in popular nomenclature can do so, using if they wish, this list as a basis for forming new vernacular names. In summary this is an excellent little book which achieves its main aims very well. It contains a great amount of information compressed into a very small space. The quality of the drawings and text is very high. It suffers from only a very few typographic errors. It will be useful throughout Victoria and the southern part of New South Wales. Given its size it may seem a little expensive, but this is more than compensated by the amount of information it provides. Available from Murray Darling Freshwater Research Centre, P.O. Box 921, Albury, N.S.W. 2640. \$38.50 (incl. GST) + \$2.30 p/p. Phone (02) 6058 2300; fax (02) 6043 1626. Address: Orders to: Murray Darling Freshw. Res. Cent., P.O. Box 921, Albury, NSW 2640, Australia

4086. Theischinger, G. (2003): Dragonfly News from Cape York Peninsula. *Austrolestes* 8: 2-3. (in English). [The paper contains different notes on the history of the discovery of *Nannophya paulsoni* Theischinger, 2003, the questionable status of *pymaea* in Australia (it should be omitted from checklists and replaced by *N. paulsoni*), a first record of *Notolibellula bicolor* Theischinger & Watson, 1977 in eastern Queensland, and the attraction of *Austrocnemis maccullochi* (Tillyard, 1926) by a UV light. Though several coenagrionid and libellulid species had been seen in the same habitat,

only *A. maccullochi* was attracted.] Address: Theischinger G., 2A Hammerley Road, Grays Point, NSW 2232, Australia

4087. Thipaksorn, A.; Jamnongluk, W.; Kittayapong, P. (2003): Molecular evidence of *Wolbachia* infection in natural populations of tropical odonates. *Current Microbiology* 47(4): 314-318. (in English). ["*Wolbachia* are endosymbiotic bacteria that cause reproductive alterations in numerous arthropod species. Using a PCR-based method, we found that, out of 33 odonate species, four species (*Agriocnemis femina*, *Pseudagrion pruinatum*, *Brachythemis contaminata*, *Neurothemis tullia*) were infected with *Wolbachia*. This finding represents the first record of *Wolbachia* infection in tropical odonates. Identical *wsp* gene sequences were found in the *Wolbachia*-infected common odonate species, *Agriocnemis f. femina*, collected from different locations in Thailand. The infection frequencies in several natural populations suggest that replacement of uninfected populations by *Wolbachia*-infected ones has recently occurred in this damselfly species." (Authors)] Address: Kittayapong, P., Center for Vectors and Vector-Borne Diseases, Faculty of Science, Mahidol University, Rama 6 Road, Bangkok, 10400, Thailand. E-Mail: grpkt@mahidol.ac.th

4088. Thipaksorn, A.; Kittayapong, P.; Jamnongluk, W.; Thirakhupt, V.; Milne, J.R.; Sindhusake, C.; Poonchaisri, S. (2003): Record of *Wolbachia* infection in zygopteran odonates. *Malangpo* 20: 206-209. (in English). ["The genus *Wolbachia* comprises rickettsia-like bacterial endosymbionts in a group of Alpha subdivision of proteobacteria that cause reproductive alterations in numerous arthropod species. [...] The infection by *Wolbachia* bacteria in odonate insects was first recorded in *Perithemis tenera*, by Jeyaprakash and Hoy (2000)." In 2003, Thipaksorn et al. (2003) reported a first recorded of *Wolbachia* infection in two zygopteran species and two anisopteran species. We caught 33 odonate species from rice fields in 36 provinces around of Thailand and screened *Wolbachia* infection by long PCR procedure with *wspL* primers. *Agriocnemis femina*, *Pseudagrion pruinatum*, *Brachythemis contaminata*, and *Neurothemis tullia* representing 12.12% (4/33) of the recorded species have been infected with *Wolbachia*. "A phylogenetic analysis of *Wolbachia* strains found in infected odonates, including the strain from the odonate, *Perithemis tenera*, and two previously published A group *Wolbachia* strains (Jeyaprakash and Hoy, 2000; Zhou et al., 1998) was conducted. All procedures used for phylogenetic reconstruction (maximum parsimony, maximum likelihood and neighbor-joining methods) place all odonate *Wolbachia* strains in a monophyletic group with those of B group *Wolbachia*. The *wsp* gene sequences of *A. femina* and *B. contaminata* were in the Pip subgroup with 100% of sequences, while the *wsp* gene sequences of *N. tullia* and *P. pruinatum* were identical and in the same Con subgroup as those of *Perithemis tenera*. The low *Wolbachia* infection frequencies and identical *wsp* gene sequences in related odonate species that are not closely related suggest that *Wolbachia* might have recently invaded rice field odonate populations through some means of horizontal transmission. Identical *wsp* gene sequences were found from all three positive populations of *A. femina* collected from different regions of Thailand may supports the hypothesis that *Wolbachia*-infected damselflies spread into uninfected populations. Further stu-

dy should be done to investigate the rates at which *Wolbachia*-infected damselflies could spread into uninfected populations." (Authors)] Address: Kittayapong, P., Department of Biology, Faculty of Science, Mahidol University, Rama VI Road, Bangkok 10400, Thailand

4094. Truscott, L.A.C. (2003): Common Blue Damselfly *Enallagma cyathigerum* (Charpentier) capturing the

Rush Veneer *Nomophila noctuella* (Denis & Schiffermüller), a pyralid moth, as a prey item. *J. Br. Dragonfly Society* 19(1/2): 38. (in English). [Verbatim: On 8 June 2003, at Bake Fishing Lakes, Trerulefoot, Cornwall, UK, I observed *E. cyathigerum* capturing *N. noctuella*. The damselfly quickly alighted, possibly because of the weight of the prey, and had already removed one of the moth's forewings. However, not much time was spent tackling the prey and the damselfly flew off after about twenty seconds without the Rush Veneer. This (attempted) prey item is by far the largest I have ever noted. This is not a large moth (the wing length of this individual was only approximately 10mm), but it is still huge compared with the tiny prey items normally caught by this and other damselflies. Adrian Parr (pers. comm.) has mentioned that there are some records of damselflies taking larger prey, such as *Lestes sponsa* tackling a crane-fly. However, in most of the literature referring to the diet of adult Odonata, the prey of damselflies is usually described as small flies or similar, so prey of this size would appear to be very unusual.] Address: Truscott, L.A.C., 59 Cremyll Road, Torpomot, Cornwall PL11 2DZ, UK

4095. Tsubaki, Y. (2003): The genetic polymorphism linked to mate-securing strategies in the male damselfly *Mnais costalis* Selys (Odonata: Calopterygidae). *Population Ecology* 45(3): 263-266. (in English). ["Alternative male mate-securing strategies are widespread among animal taxa, but there are few well-documented examples of genetic polymorphisms for them. In the Japanese calopterygid damselfly *Mnais costalis*, males occur as either orange-winged territorial fighter males, or clear-winged non-territorial sneaker males. It has previously been suggested that this behavioral polymorphism is genetically controlled. However, there was no direct evidence for this. By rearing two groups of larvae from the same female but sired by different male morphs, I show that differential morph development is genetically controlled and consistent with a single-locus two-allele autosomal genetic polymorphism." (Author)] Address: Tsubaki, Y., Biodiversity Conservation Research Group, National Institute for Environmental Studies, 305-8253 Tsukuba, Japan

4096. Vamosi, S.M. (2003): Predation sharpens the adaptive peaks: Survival trade-offs in sympatric sticklebacks. *Annales Zoologici Fennici* 39(3): 237-248. (in English). ["This study tests whether living in different lake habitats in benthic and limnetic sticklebacks (*Gasterosteus aculeatus* complex) has resulted in divergence of antipredator traits and habitat-associated survival trade-offs. Adult benthics were larger than limnetics, had poorly developed defensive armour and showed no tendency to school with conspecifics. Limnetics, in contrast, were smaller, had well developed defensive armour and demonstrated strong schooling behaviour. In littoral arenas, juvenile limnetics were significantly more vulnerable than juvenile benthics to predation by adult benthics and backswimmers (*Notonecta* sp.) but not dragonfly larvae (*Aeshna* sp.). This pattern was reversed in open water arenas when adult benthics and limnetics were exposed to diving avian predators, double-crested cormorants (*Phalacrocorax auritus*). These findings show that divergence in antipredator traits between benthic and limnetic sticklebacks has accompanied divergence in foraging traits, resulting in survival trade-offs in addition to those previously observed for foraging success and growth rates across habitats."

(2003): Première donnée d'*Ophiogomphus cecilia* (Geoffroy in Fourcroy, 1785) sur les berges de la Mayenne dans le département du Maine-et-Loire (Odonata, Anisoptera, Gomphidae). *Martinia* 19(2): 51-55. (in French with English summary). [Records of *O. cecilia* in western France are restricted to the river Loire. This record from the Mayenne (Saint-Aubin Island, north of Angers, Maine-et-Loire, France) seems to be the first record in a running water of France not belonging to the Loire river system. A total of 13 odonate species was recorded at the sampling site. Records include *Gomphus simillimus* and *Orthetrum albistylum*. The dominant species of the river

Mayenne was *Gomphus pulchellus*.] Address: Villenave, Johanna, 12, rue H. Broutelle, F-44000 Nantes, France

4102. Virbickas, J.; Pliuraite, V. (2003): The species composition of macrozoobenthos in small Lithuanian rivers. *Acta zool. lithuan.* 12(3): 254-264. (in English, with Lithuanian summary). [4 odonate species are reported from 5 (out of the 12) rivers studied during 1996-2001. Among these, *Calopteryx splendens* is frequent, while larval *Epitheca bimaculata* is considered very rare, encountered in the Brazuole R. only. The data are compared with data from small rivers in the Kaliningrad region (Russia).] Address: Virbickas, J.; Pliuraite, V., Inst. Ecol., Akademijos 2, LIT-2600 Vilnius, Lithuania

4103. Wang, H.; Zeng, L.; Liu, H.; Yin, C. (2003): Measuring wing kinematics, flight trajectory and body attitude during forward flight and turning maneuvers in dragonflies. *Journal of Experimental Biology* 206(4): 745-757. (in English). ["A robust technique for determining the wing kinematics, body position and attitude of a free-flight dragonfly is described. The new method is based on a projected comb-fringe technique combined with the natural landmarks on a dragonfly, allowing us to establish the local body-centered coordinate system with high accuracy, and to measure the body attitude at any instant. The kinematic parameters, including wing-beat frequency, flapping angle, angle of attack, torsional angle and camber deformation, required no assumptions to be made with respect to wing geometry, deformability (except the assumption of rigid leading edges) or bilateral wing symmetry. Two typical flight behaviors, forward flight and turning maneuvers, of dragonflies *Polycanthagyna melanictera* Selys were measured and analyzed." (Authors)] Address: Wang, H., State Key Laboratory of Precision Measurement Technology and Instruments, Department of Precision Instruments, Tsinghua University, Beijing, 100084, China. 4105. Werner, D.; Pont, A.C. (2003): Dipteran predators of simuliid blackflies: A worldwide review. *Medical & Veterinary Entomology* 17(2): 115-132. (in English). ["Haematophagous female blackflies (Diptera: Simuliidae) are serious biting pests and obligate vectors of vertebrate pathogens, namely filarial *Dirofilaria*, *Mansonella*, *Onchocerca* and protozoal *Leucocytozoon*. Immature stages of Simuliidae inhabit lotic waterways, the sessile larvae filter-feeding and often forming a large proportion of the benthic biomass, usually aggregated in well-oxygenated sections of streams, rivers, waterfalls and spillways. Simuliid control practices depend on larvicidal chemicals, biological products (bacteria, ne-

matodes) and environmental modification. The potential use of predators for biological control of Simuliidae has not been exploited. Predators of Simuliidae include examples of at least 12 families of Diptera and other predeaceous arthropods (Crustacea and insects: Coleoptera, Odonata, Plecoptera, Trichoptera), invertebrates (notably Turbellaria), as well as browsing fish. Diptera impacting upon simuliid populations comprise mainly Chironomidae, Empididae and Muscidae, although several other families (Asilidae, Dolichopodidae, Phoridae, Drosophilidae, Scathophagidae) play a significant role as predators. Details of predator and prey species and life stages are presented, by zoogeographical region, including the prevalence of cannibalism among Simuliidae." (Authors) Address: Werner, D. Humboldt-Universität zu Berlin, Institut für Biologie, Invalidenstr. 43, D-10115, Berlin, Germany. E-Mail: h0662cer@rz.hu-berlin.de

4110. Zambo, J.M.; Maret, T.J. (2003): Direct and indirect effects of acidification on amphibians and their invertebrate predators. *Journal of the Pennsylvania Academy of Science* 76: 143. (in English). [Verbatim: Many studies have been done on the direct effects of acidity on amphibians, but little research has been conducted on the indirect effects of acidity on the interactions between amphibians and their predators. This study examined the effects of pH on the hatching success, hatching size, and hatching time of wood frogs (*Rana sylvatica*) and green frogs (*R. clamitans*) as well as the effects of pH on predation on different sizes of *R. sylvatica*, *R. clamitans*, and American toad (*Bufo americanus*) tadpoles by dragonfly naiads (families Corduliidae and Aeshnidae). The percentage of eggs that hatched and the time it took them to hatch was significantly influenced by pH for *R. clamitans*, but not *R. sylvatica*. Size of tadpoles at hatching was not significantly affected by pH for either species. The percentage of tadpoles attacked was dependent on the size of the tadpole

for *R. sylvatica* only and was not significantly influenced by pH for any species.] Address: Zambo, J.M., Department of Biology, Shippensburg University, Shippensburg, PA, 17257, USA

2004

4111. Abro, A. (2004): Structure and function of the male sperm ducts and female sperm-storage organs in *Aeshna juncea* (Anisoptera: Aeshnidae). *Odonatologica* 33(1): 1-10. (in English). ["By the use of light and electron microscopy, the micro-anatomy of the S genital ducts and the 9 reproductive organs have been surveyed. Sperm bundles transmitted from the testis through the vas deferens become embedded in a carrier jelly and also have additional substances bound to them; obviously the sperm cells are undergoing maturation. In the 9 9, sperm bundles in carrier jelly appear to be deposited in the vaginal canal and, particularly, in the receptaculum seminis, the latter serving for long-term conservation. It seems possible that agents emitted from the posterior accessory glands to the vaginal surface near the genital aperture diffuse forwards, reaching the receptacle entrance. Here they presumably induce a liquefaction of the jelly and break-down of sperm bundles, thus releasing individual sperm cells. Free sperm cells are expected to accumulate in the anterior accessory sacs which they leave during fertilization. The morphological changes taking place in the sperm after transfer to the 9 genital tract appear ambiguous." (Author)] Address: Abro, A., Department of Anatomy, University of Bergen, Jonas Lies vei 91, N-5009 Bergen, Norway

4113. Askew, R.R. (2004): *Dragonflies of Europe* - Revised edition in paperback. ISBN 0 946589 75 5: 308 pp. (in English). [When in 1992 I travelled to Italy and Greece for odonatological purposes, I had to make a quite difficult decision: Should I take Askew's weighty book along or should I leave it at home? In the future there will be no such problem: The revised edition of R.R. Askew's "The Dragonflies of Europe" will be released in a new, slightly reduced, paperback format (232 x 168 mm), and will fit into everybody's backpack. But, after browsing the book there will be an additional question: Is it worth being taken to the field? My personal opinion is that the chance to write an up to date book on European Odonata was missed.

After its publication fifteen years ago, this book was almost unanimously considered as the finest handbook ever produced on European Odonata. More than 3000 copies of the original hardback edition have been sold! In the revised edition, the author has made a few corrections and changes to the original text, which covered 114 species of Odonata breeding in Europe and added a new Preface and an updating Supplement. The Introduction, which seems to me unchanged, is followed as in the first edition by the chapters Life History, The Adult Dragonfly, The Distribution of European Dragonflies, Morphology of the Adult Dragonfly, The European Species of Odonata including an updated Check-

list, and finally Keys to the Final-Instar Larvae of European Odonata

The Systematic section includes keys to the suborders, families, genera, and species, species accounts with clear descriptions and details on biology, flight periods, and distribution of all species found in Europe, with distribution maps with national boundaries as they were in 1988. The status of information in all aspects is that of the first edition, except the updated checklist. Nevertheless, in the revised edition the excellent plates of the first edition have lost their brilliance.

The chapter on larvae is now followed by a Supplement, intended as the up date of the first edition in paperback format. R.R. Askew provides new information under the following headings: Nomenclature, Orthography, Thermoregulation, American species observed in Europe, Accidental Introductions into Europe (these are species imported together with aquatic plants for aquaria and which emerged in greenhouses), Other species newly recognized in Europe, Species new to British Isles, Expansion of recorded ranges within Europe, Other new distribution records, and Contraction of recorded ranges. As a supplement to the chapter References, the author lists more than 100 references on European Odonata published after 1988.

The supplement with numerous line-drawings is followed by a new index to English and scientific names, including all species, subspecies and synonyms cited in the revised text. An additional colour plate (number 30) depicts adults of the five "new" records and one from North America.

R.R. Askew has added a further ten resident species, and several adventures to the European checklist of species. The serious problems with this revised edition are starting here: A new species of the European fauna (*Sonjagaster helladica*, Lohmann 1993) described after the first edition of the book is omitted with the exception of a footnotelike note on page 213. Species not illustrated in the first edition like *Ischnura hastata*, *I. saharensis* and *Platycnemis subdilitata* (both from Canary Islands), and *I. fountaineae* are likewise not illustrated in the revised edition. *P. subdilitata* is not mentioned in the chapter of species newly recognized in Europe, but listed in the chapter of new distribution records. Serious examples of inadequate representation of important species in a book on European Odonata are *Boyeria cretensis* Peters 1991 and *Coenagrion intermedium* Lohmann, 1990. In the case of *B. cretensis* the differences between *B. irene* and *cretensis* are briefly described; for a drawing of *B. cretensis* there is a cross reference (!) to a paper of J.-P. Boudot and – in addition – not to the original description! In the case of *C. intermedium*, the species status is discussed, but *C. ponticum* is illustrated! *Somatochlora meridionalis* Nielson 1935 is accepted as a good species, but no illustration or any description of the morphological differences to *S. metallica* are given. In the revised edition of a book claiming to cover the European dragonfly fauna, the reader can expect a complete list of species and illustrations of all European species.

It remains a real secret to me what kind of useful information is intended in the chapter "Other new distribution records" which is a list of species and distributional information from different sources: Many information remain on a more regional scale while some contain quite precise information on the locality level. What kind of criteria to select or to omit records were chosen remains really unclear. Additions to the Odonata of France are reduced to information on Corsica (Chapter "Re-

cent literature"). The distribution maps and the accompanying texts of the first edition were in need of revision. The list of localities presented can not be a substitute of up-dated distribution maps.

The supplementary plate illustrates *Anax immaculifrons*, *A. junius*, *Orthetrum sabina*, *O. taeniolatum*, *Sympetrum sinaiticum*, and *Trithemis festiva*; the pictures are looking quite fine, and will be appreciated especially in cases of the very rarely pictured species like *A. immaculifrons* and *S. sinaiticum*. *Somatochlora borisi* is illustrated as black and white drawing and with a colour photo on the title page of the book. Being not acquainted with *A. immaculifrons* I cannot judge on the colours of the picture on plate 30, but I believe they are too pale (compare e.g.: <http://www.asia-dragonfly.net/picSearch-Species.php?Species=104> 3)

There remains a certain kind of sadness: the revised edition of a really outstanding book turns out to me as nearly completely unuseable if you are the happy owner of the first edition. If you didn't have had the chance to buy Askew's book, now you have it. But don't expect a book that keys or covers all European odonate species. (Martin Schorr) Address: Harley Books, Martins, Great Horkeley, Colchester, Essex CO6 4AH, UK. E-mail: harley@keme.co.uk. £30,- net.

4114. Barlow, A.E. (2004): Adverse weather and its impact on Odonata flights seasons. New record late dates from New Jersey. *Argia* 15(4): 21-22. (in English). 4115. Beckemeyer, R. (2004): Aerobic Anisoptera & zooming Zygoptera: Odonata flight from A to Z. *Argia* 15(4): 6-8. (in English). ["Key facts: (1) Wing Loading is just the weight of the insect divided by the total area of its wings. (2) The wing loading indicates the average differential pressure that the air must exert on the wings to support the insect in flight. (3) Lower wing loadings mean the insect can fly at lower speeds." (Author)] Address: Beckemeyer, R.J., 957 Perry Ave., Wichita, KS 67203-3141, USA. E-mail: royb@southwind.net

4116. Beckemeyer, R. (2004): Aerobic Anisoptera & zooming Zygoptera: Odonata flight from A to Z. Part 2. Dragonfly wings: responding to pressure. *Argia* 16(1): 4-9. (in English). ["Key facts: Wing loading indicates the average differential pressure that must be generated by aerodynamic forces acting on the wing to support it in flight. The actual pressure distribution across the chord of the wing from leading to trailing edge is not uniform, but has a large peak "suction" (pressure lower than atmospheric) area near the leading edge. Insect wings reflect this pressure distribution in having their corrugated longitudinal veins (costa, subcosta, radius) clustered near the costal margin (leading edge). Wings can only generate lift if they are inclined at a leading edge up (positive) angle of attack, or if they have a positive camber (convex dorsal curvature). A wing with positive camber will generate more lift than a flat wing at the same angle of attack." (Author) *Anax junius*] Address: Beckemeyer, R.J., 957 Perry Ave., Wichita, KS 67203-3141, USA. E-mail: royb@southwind.net

4117. Beckemeyer, R. (2004): Some Odonata records for the midwest and west for 2003. *Argia* 16(1): 26. (in English). [USA, Oklahoma, Idaho, Illinois, Kansas] Ad-

4121. Buczyński, P. (2004): Gorb, S.N.; Pavljuk, R.S.; Spirus, Z.D. (2000): Odonata of Ukraine. A faunistic overview. *Vestnik zoologii, Suppl.* 15. 154 pp.. *Wiadomości Entomologiczne* 22(1): 18. (in Polish). [Detailed and critical review of the book on the Ukrainian Odonata.] Address: Buczyński, P., Dept of Zool., Mariae Curie-Skłodowska University, Akademicka 19, PL-20-033 Lublin, Poland. E-mail: pbuczyns@biotop.umcs.lublin.pl

4122. Buczyński, P.; Zawal, A. (2004): New data about the occurrence of protected dragonflies Odonata in north-western Poland. *Chrońmy Przyrodę Ojczyzną* 60(1): 53-66. (in Polish with English summary). ["New data about the occurrence of *Aeshna viridis*, *Leucorrhinia albifrons*, *L. caudalis* and *L. pectoralis* are given. The material was collected in the years 1998-2001, from nine sample sites (Fig. 1): Krajnik (meadows at the River Odra), Binowo (Binowo Lake), Czermnica (a forest dystrophic water body), Żabowo (a forest dystrophic water body), Potczyn-Zdrój ("Valley of Five Lakes" nature reserve - Krąg Lake and Długie Lake), Lubowo (Lubicko Wielkie Lake), Borne-Sulinowo (forest dystrophic water body and transitional peat bog). Based on new records and on literature it can be stated that *L. albifrons* and *L. pectoralis* are relatively common in the north-western Poland (Fig. 2), whereas *A. viridis* and *L.*

caudalis are known from few localities. It may partially be the result of highly incomplete knowledge about the dragonfly fauna of the area. The characteristics of its habitat and the state of nature indicate that in fact the species may be much more frequent there. The mentioned species are protected in Poland due to their presence in the Annex II to Bern Convention, which reflects the situation in western Europe in 1970s. They are undoubtedly endangered. *L. caudalis* is on the Polish Red List of Threatened Animals in Poland in the category "Near Threatened", *A. viridis* and *L. albifrons* in "Least Concern", and *L. pectoralis* is not included on the List. Therefore their protection is being questioned. But the situation of the mentioned species in Germany, Czech Republic and Slovakia is serious (Tab. 1). Poland is the westernmost country of Central Europe, where the populations of the species are stable and little endangered. [...] The situation puts a great responsibility on Poland to preserve and protect the species. Besides, threats to dragonflies in Poland are similar to those in western Europe, though they are not as intensive. It is hard to forecast their progress. For that reason the monitoring of highly endangered species is desirable." (Authors)] Address: Buczyński, P., Dept of Zool., Maria Curie-Skłodowska University, Akademicka 19, PL-20-033 Lublin, Poland. E-mail: pbuczyns@biotop.umcs.lublin.pl

4123. Caldwell Rinehart, S.; Hovemann, A.C. (illust.) (2004): *Eliza and the dragonfly*. Dawn Publications. ISBN-58469-059-3: 32 pp. (in English). ["*Eliza and the Dragonfly*" is not primarily an instructive book (apart from two pages in the end of the book), but is designed to introduce children to the joys of actually looking for dragonflies. It develops attitudes more than it instructs. The book is richly illustrated with water-colour sketches of a little girl, her aunt, some friends, and dragonflies (named "Horace"). The illustrations might be more impressionistic than children appreciate. The strength of the book is the tying together of the pond habitat for the nymph and its development into a flying insect. Is this a children's book? I really don't know. But I do know that I enjoyed all the pictures and I do not want to miss it in my library. (Martin Schorr)] Address: Dawn Publ., 12402 Bitney Springs Road, Nevada City, CA 95959, USA. E-mail: nature@dawnpub.com

4124. Carvalho, A.L.; Salgado, L.G.V. (2004): Two new species of *Aeshna* in the punctata group from southeastern Brazil (Anisoptera: Aeshnidae). *Odonatologica* 33(1): 25-39. (in English). ["Based on material from the states of Rio de Janeiro and Minas Gerais, *A. serrana* sp. n. (holotype male: Serra do Subaio, Teresopolis, Rio de Janeiro State) and *A. itatiaia* sp. n. (holotype male: Brejo da Lapa, Itamonte, Minas Gerais State) are described and illustrated. The type material is to be deposited in the Museu Nacional and in the Instituto de Biologia, UFRJ, Rio de Janeiro. Morphological features of the 2 new species are compared in a table and SE Brazilian members of the punctata group (that includes also *A. decessus*, *A. eduardoi* and *A. punctata*) are keyed." (Authors) Note: The great revision of the genus *Aeshna* in Southamerica by N. von Ellenrieder (2003) (see OAS ..) was not considered in this publications. It is quite reasonable that both sp. n. have to be transferred to the genus *Rhionaeschna*.] Address: Carvalho, A.L., Departamento de Entomologia, Museu Nacional, Universidade Federal do Rio de Janeiro
