essary changes, new assessments and updates for the African dragonflies (to be entered in the SIS in 2014). In February 2013, a project on *Amanipodagrion gilliesi* assessed as Critically Endangered on The IUCN Red List, was started in collaboration with the Tanzanian Forest Conservation Group and the Amani Nature Reserve, and funded by the Mohamed bin Zayed Species Conservation Fund. The project aims to raise awareness of the rarity of the dragonfly and on the connection of biodiversity, environmental quality and human well being. Another project funded by the Mohamed bin Zayed Species Conservation Fund, focused on *Xanthocnemis sobrina*, which is endemic to the New Zealand North Island. It is the only representative of its group in the country, assessed as Data Deficient on The IUCN Red List. The project aims to clarify some uncertainties around the taxonomy of the species and to assess its current conservation status. We are aiming to have all dragonflies on The IUCN Red List by 2016. This requires a lot of work, and involves many meetings (especially with regards to the assessment of South America's dragonflies), this will become difficult without external funding. The Powder Blue Damselfly (*Arabicnemis caerulea*) was featured as an Amazing Species on The IUCN Red List website, and *Amanipodagrion gilliesi* will be featured in 'No More Endlings: saving species one story at a time' by Allison Hegan. In South Africa, the recently established Dragonfly Biotic Index (DBI) is becoming popular for environmental impact assessments and habitat monitoring. 14132. Coccia, C.; Boyero, L.; Green, A.J. (2014): Can differential predation of native and alien corixids explain the success of *Trichocorixa verticalis verticalis* (Hemiptera, Corixidae) in the Iberian Peninsula? *Hydrobiologia* 734: 115-123. (in English) ["Invasive species represent an increasing fraction of aquatic biota. However, studies on the role and consequences of facilitative interactions among aliens remain scarce. Here, we investigated whether the spread of the alien water boatman *Trichocorixa verticalis verticalis* in the Iberian Peninsula is related to reduced mortality from predation compared with native Corixidae, especially since *Trichocorixa* co-occurs with the invasive fishes *Gambusia holbrooki* and *Fundulus heteroclitus*. All three invaders have a common native range in North America and are widespread in and around Doñana in SW Spain. Using laboratory experiments, we compared the predation rates by the two exotic fish and native Odonata larvae (*Orthetrum*, *Sympetrum*, *Crocothemis*, *Aeshna*) on *Trichocorixa* and the native *Sigara lateralis*. We found no evidence to suggest that *Trichocorixa* suffers lower predation rates. However, when both corixids were mixed together, predation of *Trichocorixa* by Odonata larvae was higher. Odonata larvae were size-limited predators and the proportion of corixids ingested was positively correlated with mask length. Since *Trichocorixa* is smaller than its native com-

petitors, this may explain their higher susceptibility to predation by Odonata. This may be one of various factors explaining why *Trichocorixa* is particularly dominant in saline habitats where Odonata are rare, while it is still scarce in fresh waters." 14133. Cockburn, J.J.; Khumalo-Seegelken, B.; Villet, M.H. (2014): IziNambuzane: IsiZulu names for insects. *S. Afr. J. Sci.* 110(9/10), Art. #2013-0292: 13 pp. (in English) ["We provide a tool for communicating about insects in isiZulu to facilitate research and knowledge sharing in the fields of indigenous knowledge, cultural entomology, environmental education and community extension involving isiZulu speakers. A total of 213 different names for 64 insect specimens were encountered among a sample of 67 respondents in 11 communities distributed across the province of KwaZulu-Natal, South Africa. This list includes 93 names that can be considered core isiZulu vocabulary and which are widely used to identify insects that are agriculturally, medically, domestically, culturally or ecologically common or significant. Substantial variation was found regarding the names for particular insects, especially between regions, suggesting dialectal differences between isiZulu speakers. Grammatical and social variation in names was also recorded. This study highlights interdisciplinary teamwork in the field of indigenous knowledge research and the influences affecting the standardisation of South African languages for technical and scientific work. ... In areas north and northeast of the Thukela River and northeast of the Phongolo River, isiZulu speakers call dragonflies (Odonata) *ibhebhamanzi* or *amabhebhamanzi*, but these terms were not reported to the interviewers, apparently because they are considered impolite. ... For example, dragonflies (Odonata: Anisoptera) are most commonly indicated by the stem *-jekamanzi*, but the prefix (and therefore the noun class) of this varies depending on the geographical region in focus. ... It appears that isiZulu names do not go beyond the taxonomic resolution of family-level identification, and are more easily comparable to names accorded the Linnean taxonomic rank of 'order'. For example, *ujekamanzi* corresponds to the order Odonata, *ibhungane / ibhungezi / ibhungayezi* to the Coleoptera (beetles *sensu stricto*), depending on which region the speaker is in, and *umnyovu / umuvi* to the Hymenoptera (wasps, but excluding ants and bees). ... Crane flies, robber flies and antlions were all referred to as *ujekamanzi*, although the reference to water (*-manzi*) in that name clearly aligns it with the biology of the dragonflies and damselflies that it also denotes. However, all of these specimens were large, with elongated abdomens and clear wings, so *ujekamanzi* may be understood to designate a physical form rather than a specific taxon, in analogy to the terms 'pest' and 'bug' and 'germ' in English folk taxonomy, *inunu* in isiZulu or *gogga* in Afrikaans." 14135. Couto-Mendoza, M.T.; Servia, M.J.; Cobo, F. (2014): Regeneration interferes with fluctuating asymmetry analysis in odonate larvae. *Limnetica* 33(1): 107-120. (in English, with Spanish summary) ["When an odonate larva loses a leg, it has the ability to regenerate it in the next moult. In this study, our goal was to test whether this ability affects fluctuating asymmetry analyses (FA) using *Calopteryx virgo* larvae. We observed that asymmetries in the femur and tibia caused by regeneration in field samples are not always detected as outliers, and therefore they are not automatically eliminated by statistical tests. However, they increased the value of the composite index of asymmetry by approximately 30 % with respect to the sample where all of the cases of regeneration were eliminated. Next, we wanted to test whether costs associated with leg regeneration had an effect on the development of other structures by increasing the level of fluctuating asymmetry in this species. The results confirmed that the value of the composite index of asymmetry calculated using antennal and mask measures was significantly higher for individuals that had a regenerating leg. Thus, prior knowledge of the biology and the physiology of the traits of the species under study should be an essential topic in fluctuating asymmetry studies to guarantee reliable results, as regeneration ability clearly interferes in fluctuating asymmetry analysis in odonate larvae." 14137. Dinh Van, K.; Janssens, L.; Debecker, S.; Stoks, R. (2014): Temperature and latitude-specific individual growth rates shape the vulnerability of damselfly larvae to a widespread pesticide. *Journal of Applied Ecology* 51(4): 919-928. (in English) ["(1) Freshwater ecosystems are especially vulnerable to climate change and pollution. One key challenge for aquatic toxicology is to determine and manage the combined effects of temperature increase and contaminants across species' ranges. (2) We tested how thermal adaptation and life-history evolution along a natural temperature gradient influence the vulnerability of an aquatic insect to a pesticide under global warming. We applied a space-for-time substitution approach to study the effect of warming on the vulnerability of *Ischnura elegans* damselfly larvae to the pesticide chlorpyrifos in a common garden warming experiment (20 and 24°C) with replicated populations from three latitudes spanning >1500 km in Europe. (3) Chlorpyrifos was more toxic to damselfly larvae at the higher temperature: mortality only occurred at 24°C and the reductions in growth rate were stronger at 24°C. This could partly be explained by parallel reductions in food intake but not by the activities of two widespread enzymatic biomarkers, glutathione S-transferase (GST) and acetylcholinesterase (AChE). (4) There was some evidence that the increased toxicity of the high chlorpyrifos concentration at 24°C was stronger in terms of growth reduction in the faster-growing larvae from the low-latitude populations. This is consistent with energy allocation trade-offs between growth rate and pesticide tolerance, but suggests that local thermal adaptation does not play a role in coping with pesticide stress. (5) Synthesis and applications. Damselfly larvae from populations in lower latitudes were more vulnerable to a common pesticide at higher temperatures and pesticide concentrations, whereas evidence for the influence of local thermal adaptation on the vulnerability of larvae was weak. These results emphasize the need for spatially explicit bioassessment and conservation tools. Management practices aimed at mitigating pesticide run-off into aquatic ecosystems are particularly important in agricultural areas at low latitudes." 14138. Dodds, R.M. (2014): *The Dragonfly Diaries: The unlikely story of Europe's first dragonfly sanctuary*. Saraband. ISBN-10: 1908643552: 304 pp. (in English) ["Britain is home to some 40 species of dragonfly, and public interest in their plight is high right now thanks to their primeval beauty, aerobic grace and a growing realisation of their importance for water ecosystems. In *The Dragonfly Diaries*, Dodds shares his quirky fascination for these remarkable creatures over the 25 years he has been photographing and working with them. Combining fascinating description of the lives of dragonflies, with a diary chronicling the ups and downs of establishing Britain's first public dragonfly sanctuary, *The Dragonfly Diaries* is a must for nature buffs and for anyone who wants

to be inspired by the resolve and dedication of a man on a mission to save these critically important insects." (Publisher)] Address: not stated

14139. Dolný, A.; Harabiš, F.; Bárta, D.; Lhota, S.; Drozd, P. (2014): Aquatic insects indicate terrestrial habitat degradation: changes in taxonomical structure and functional diversity of dragonflies in tropical rainforest of East Kalimantan. *Tropical Zoology* 25(3): 141-157. (in English) ["Odonata are commonly used as ecological indicators of freshwater ecosystems. Despite earlier studies suggesting that adult odonates may be good indicators for complex changes in a landscape, the utility of odonates as suitable indicators to indicate health of non-aquatic (forest) habitats remains poorly understood. This study analyses the adult dragonfly assemblage pattern against spatial and temporal disturbance characteristics in Indonesia's Sungai Wain Protection Forest. The core of this reserve comprises one of the few remaining fragments of primary rain forest along the East Kalimantan coast, whereas the rest of the reserve is covered by secondary forest, scrub, grassland, and farmland. Adult dragonfly assemblages at individual sampling sites were analysed in relation to (1) their intensity, (2) frequency of human-caused disturbances, and (3) the time since the last such disturbance, while controlling random variables (type of aquatic and terrestrial habitat) were removed. This study tests the effect of these factors on (1) species richness, (2) proportion of Zygoptera, (3) proportion of

forest specialists, and (4) proportion of Borneo's endemics. The human-induced disturbances in the rain forest resulted in pronounced changes in the taxonomical composition and functional diversity of the odonate fauna. Results reported here demonstrate that gradual changes in the odonate assemblages correspond to the degree of anthropogenic influences on forest environments. Adult odonates comprise an appropriately sensitive and versatile indicator group for identifying changes in terrestrial forest environments as well as in freshwater habitats." 14140. Dolný, A.; Harabiš, F.; Mizicova, H. (2014): Home range, movement, and distribution patterns of the threatened dragonfly *Sympetrum depressiusculum* (Odonata: Libellulidae): A thousand times greater territory to protect? *PLoS ONE* 9(7): e100408. doi:10.1371/journal.pone.0100408: 10 pp. (in English) ["Dragonflies are good indicators of environmental health and biodiversity. Most studies addressing dragonfly ecology have focused on the importance of aquatic habitats, while the value of surrounding terrestrial habitats has often been overlooked. However, species associated with temporary aquatic habitats must persist in terrestrial environments for long periods. Little is known about the importance of terrestrial habitat patches for dragonflies, or about other factors that initiate or influence dispersal behaviour. The aim of this study was to reveal the relationship between population dynamics of the threatened dragonfly species *Sympetrum depressiusculum* at its natal site and its dispersal behaviour or routine movements within its terrestrial home range. We used a mark–release–recapture method (marking 2,881 adults) and exuviae collection with the Jolly–Seber model and generalized linear models to analyse seasonal and spatial patterns of routine movement in a heterogeneous Central European landscape. Our results show that utilisation of terrestrial habitat patches by adult dragonflies is not random and may be relatively long term (approximately 3 mo). Adult dragonflies were present only in areas with dense vegetation that provided sufficient resources; the insects were absent from active agricultural patches ($p = 0.019$). These findings demonstrate that even a species tightly linked to its natal site utilises an area that is several orders of magnitude larger than the natal site. Therefore, negative trends in the occurrence of various dragonfly species may be associated not only with disturbances to their aquatic habitats, but also with changes in the surrounding terrestrial landscape." 14145. Dreyer, J.; Gratton, C. (2014): Habitat linkages in conservation biological control: lessons from the land-water interface. *Biological Control* 75: 68-76. (in English) ["Highlights: • Aquatic-terrestrial and crop-noncrop linkages are conceptually similar. • Exchanges in agroeco-

systems are governed by natural enemy production and dispersal. • Donor habitats on the landscape determine the coverage of dispersal. • Land-cover/use and climate change will impact habitats, natural enemy exchange. Terrestrial landscapes, including those with embedded agroecosystems, are a mosaic of cover types varying in size. Creating or maintaining habitats that support natural enemy populations to combat agricultural pests is the primary method of conservation biological control. Non-crop habitats can be managed in an attempt to maximize the exchange of natural enemies with adjacent agroecosystems with the expectation that they will suppress damaging pest outbreaks. Despite this goal, current habitat management relying on natural enemy spillover into crops has been unreliably effective at reducing pest abundance or increasing crop yield. Furthermore, the expansion and intensification of agriculture and changes in global climate patterns threaten the foundations of conservation biological control in future agroecosystems. However, the aquatic-terrestrial interface offers a natural boundary similar to the one between agroecosystems and their neighbouring non-crop habitats that can provide useful insights to the challenges facing growers. Research of the exchanges between water and land suggests general biological and physical processes that govern the movement of organisms between disparate habitats. We propose that like aquatic insects moving from water to land, natural enemy dispersal from non-crop donor habitats into recipient crop patches on the landscape is a function of (1) the production of natural enemies in the source habitat which establishes the abundance of organisms that can disperse, (2) how and why mobile natural enemies disperse themselves into neighbouring recipient habitats, and (3) the configuration of donor and recipient habitats on the landscape. We suggest that conservation biological control practitioners can focus on these main components of natural enemy production and dispersal to predict the effectiveness of conservation biological control measures and guide their adaptation to future global change." (Authors) The publication includes several references to Odonata.] Address: Dreyer, J., Dept Ent., Univ. of Wisconsin-Madison 444 Russell Laboratories 1630 Linden Drive Madison, WI 53705, USA. 14146. Egea-Serrano, A.; Hangartner, S.; Laurila, A.; Räsänen, K. (2014): Multifarious selection through environmental change: acidity and predator-mediated adaptive divergence in the moor frog (*Rana arvalis*). *Proc. R. Soc. B* 2014 281, 20133266, published 19 February 2014: 10 pp. (in English) ["Environmental change can simultaneously cause abiotic stress and alter biological communities, yet adaptation of natural populations to co-changing environmental factors is poorly understood. We studied adaptation to acid and predator stress in six moor frog populations along an acidification gradient, where abundance of invertebrate predators increases with increasing acidity of *R. arvalis* breeding ponds. First, we quantified divergence among the populations in anti-

predator traits (behaviour and morphology) at different rearing conditions in the laboratory (factorial combinations of acid or neutral pH and the presence or the absence of a caged predator: *Aeshna* dragonfly larva)). Second, we evaluated relative fitness (survival) of the populations by exposing tadpoles from the different rearing conditions to predation by free-ranging dragonfly larvae. We found that morphological defences (relative tail depth) as well as survival of tadpoles under predation increased with increasing pond acidity (under most experimental conditions). Tail depth and larval size mediated survival differences among populations, but the contribution of trait divergence to survival was strongly dependent on prior rearing conditions. Our results indicate that *R. arvalis* populations are adapted to the elevated predator pressure in acidified ponds and emphasize the importance of multifarious selection via both direct (here: pH) and indirect (here: predators) environmental changes." 14148. Emeljanov, A.F. (2014): The evolutionary role and fate of the primary ovipositor in insects. *Entomological Review* 94(3): 367-396. (in English) ["The development of a piercing-sawing ovipositor for introducing eggs into living plant tissues has made its owners independent of the soil characteristics and increased egg protection. This was the most important prerequisite for the appearance of wings and flight which provided the winged insects with tremendous opportunities for finding new niches and led to unparalleled adaptive radiation. The ovipositor has passed several stages of improvement and differentiation. The four principal types of the primary ovipositor are considered: those of Odonata, Diaphanopteroidea (only extinct forms), Cicadina (including Paraneoptera and Hymenoptera), and Orthoptera. A new hypothesis of the gonangulum homologies is put forward, interpreting it as half of sternite IX lateral of the midline

plus the paratergite of the same segment. The constructions of the valvae and different homologies of the third valvae in Polyneoptera and Eumetabola are discussed. The primary ovipositor has been repeatedly (i.e., in many lineages) reduced in the evolution of Pterygota. The main circumstances of these reductions are: (1) subterranean (fossorial) life in narrow cavities; (2) aquatic life of the larvae, mostly linked with submerged oviposition; (3) development and perfection of flight to which the heavy and protruding ovipositor was a hindrance. All the holometabolous insects except Hymenoptera lack the primary ovipositor." 14151. Fauziyah, S.; Alam, C.; Soesilohadi, R.C.H.; Retnoaji, B.; Alam, P. (2014): Morphological and mechanical characterisation of the hindwing nodus from the Libellulidae family of dragonfly (Indonesia). *Arthropod Structure & Development* 43(2): 415-422. (in English) ["Highlights: •We study functional morphology and structure of wing nodi from seven Indonesian Libellulidae species. •Nodal resilin morphology is species dependent. •Dorsal face resilin is inherently smaller than ventral face resilin. •Mechanical properties of resilin in nodus is related to its elongation shape factor. •We propose useful clues in advanced biomimetic jointing technology. In this communication, the morphologies and mechanical characteristics of nodi from the hindwings of seven Indonesian Libellulidae dragonfly species are identified. Geometrical analyses reveal that in all species, the shape of dorsal face resilin is relatively long and thin while ventral face resilin covers a greater surface area than dorsal face resilin, and is shaped like a hook. Finite element analyses reveal that the magnitude of strain energy may differ considerably between species, even though the locations of highest strain energy are usually the same.

Importantly, a correlation is found to exist between the mechanical forces that build up in the resilin, the face under investigation (dorsal or ventral) and the elongational shape factor of the resilin." Aerial Vehicle inspired by the mechanics of dragonfly flight. Towards Autonomous Robotic Systems Lecture Notes in Computer Science 2014: 90-100. (in English) ["Dragonfly flight is unique: Dragonflies can manoeuvre in all directions, glide without having to beat their wings and hover in the air. Their ability to move each of their four wings independently enables them to slow down and turn abruptly, to accelerate swiftly and even to fly backwards. We looked into the mechanics of the dragonfly flight and managed to transfer its flight dynamics into an ultralight flying object: the BionicOpter. With a wingspan of 63 cm and a body length of 44 cm, the model dragonfly weighs just 175 g. A brushless motor actuates the four wings and is used to alter the flapping frequency. Eight servo motors allow the amplitude and the twisting angle of each wing to be changed independently making the BionicOpter almost as agile and fast as its natural role model. Here we present how dragonfly flight dynamics can inspire future design of MAVs." (Authors)] Address: Gaissert, Nina, Bionic Learning Network, Festo AG & Co. 14155. Gerlach, J.; Samways, M.J.; Hochkirch, A.; Seddon, M.; Cardoso, P.; Clausnitzer, V.; Cumberlidge, N.; Daniel, B.A.; Black, S.H.; Ott, J.; Williams, P.H. (2014): Prioritizing non-marine invertebrate taxa for Red Listing. *Journal of Insect Conservation* 18(4): 573-586. (in English) ["The IUCN Red List of threatened species is biased towards vertebrate animals, a major limitation on its utility for overall biodiversity assessment. There is a need to increase the representation of invertebrates (currently 21 % of species assessed on the List; <1 % of all invertebrates). A prioritisation system of terrestrial and freshwater groups is presented here, categorising taxa by species richness, assessment practicality, value for human land use and bioindication, and potential to act as conservation flagships. 25 major taxonomic groupings were identified as priorities, including the Annelida, Arthropoda, Mollusca, and Onychophora. Of these, the high-level taxa that emerge as highest priorities are Odonata, Araneae (spiders), Mantophasmatodea (heelwalkers), Plecoptera (stoneflies), non-marine Mollusca (Bivalvia and Gastropoda), Trichoptera (caddisflies), Coleoptera (beetles), Lepidoptera (moths and butterflies), Oligochaetes (earthworms), Orthoptera (grasshoppers and crickets), Decapoda (crayfish, crabs, shrimps) and Diptera (flies). Of these Red Listing is well advanced for Decapoda, freshwater Mollusca and Odonata. This leaves eight higher taxa with currently a minimum or patchy Red List assessment coverage. We recommend that Red List assessments in future focus on these groups, as well as completion of assessments for terrestrial Molluscs and Odonata. However, we also recommend realism, and as some of groups are very large, it will be necessary to focus on subsets such as certain functionally important or charismatic taxa or on a sampled subset which is representative of a larger taxon." 14156. Grand, D.; Boudot, J.-P. (2014): Cahier d'identification des Libellules de France, Belgique, Luxembourg et Suisse. éditions Biotope. 176 pp (in French) ["This guide includes everything that is needed to identify dragonflies in the field. All 103 species dragonflies (subspecies included) are illustrated with photographs of males and females, by drawings and a concise distribution map providing an indication of abundance. The habitat is described and possible confusion between very similar species are reported. Flight periods are indicated. The guide includes an identification key to all identifiable larvae in the field. General chapters on the life cycle of dragonflies, their habitats and their anatomy are included to help you find and identify dragonflies in the field. The authors have updated the nomenclature, added three new species for France (*Brachythemis impartita*, *Orthetrum trinacria*, *Lindenia tetraphylla*), and updated the distribution maps." 14157. Gyulavári, H.A.; Therry, L.; Dévai, G.; Stoks, R. (2014): Sexual selection on flight endurance, flight-related morphology and physiology in a scrambling damselfly. *Evolutionary Ecology* 28(4): 639-654. (in English) ["We have limited knowledge on the mechanistic base of

sexual selection, especially in scrambling species. This asks for a functional approach that explores the link between each component of the phenotype-performance-fitness axis and that includes both morphological and physiological traits. We explored the phenotype-performance-fitness axis in the scrambling damselfly *Coenagrion puella* by studying the links between a set of physiological and morphological traits, flight performance (flight speed and flight endurance), and short-term mating success. As expected for scrambling competition, there was sexual selection for increased flight endurance rather than for increased flight speed. For fat content, we could demonstrate the full phenotype-performance-fitness axis, where selection for a higher fat content could be explained by the sexual selection for a higher flight endurance and the positive covariation between fat content and flight endurance. For three other traits (size, relative flight muscle mass and wing loading), however, we detected selection that could not be explained via their effect on flight performance, generating novel testable hypotheses about how the covariation between these traits and mating success is generated. This also urges caution when using morphological traits as proxies for flight speed and flight endurance in phenotypic selection studies." Conserv.* 18: 307-315. (in English) ["Odonates contribute highly to global biodiversity and are considered good indicators of environmental quality, but they are under-studied and quantitative information on their habitat associations is lacking. Our objective was to examine the effects of landscape configuration on site occupancy and movement dynamics of four odonate species in Iowa: *Tramea onusta*, *Epithea princeps*, *Pantala flavescens*, and *Calopteryx maculata*. We conducted standardized visual encounter surveys for odonates at 233 public properties in Iowa from 2007 to 2011 and computed landscape variables within a 200, 600 m, and 1 km radius of each surveyed site. Using a robust design occupancy model in Program MARK, we estimated detection probability and site occupancy, site extinction, and site colonization probabilities for each species. We found

few significant effects of landscape variables on site occupancy, extinction, or colonization, although landscape variables at 600 m were included in the best model for all species. Detection probability (SE) ranged from 0.30 (0.04) for *Pantala flavescens* to 0.49 (0.04) for *Calopteryx maculata*. Our study provides information to aid habitat restoration and management efforts on sites having suitable characteristics in the surrounding landscape and ultimately help conserve odonates." 14161. Heiser, M.; Dapporto, L.; Schmitt, T. (2014): Coupling impoverishment analysis and partitioning of beta diversity allows a comprehensive description of Odonata biogeography in the Western Mediterranean. *Organisms Diversity & Evolution* 14: 203-214. (in English) ["Islands host a subset of organisms occurring at their sources, and these assemblages are usually dominated by the most generalistic and dispersive species. In this study, we aim to identify which species are missing on islands and which ecological traits are responsible for differential occurrence. Then, we apply this information to beta diversity analyses. As a study group and area, we selected the Odonata in the Western Mediterranean. Based on the presence/absence of 109 species, we applied a series of analyses at both community and individual species level. The islands of the Balearics, Corsica, Sardinia and Malta are highly impoverished, but Sicily is not. Non-parametric multivariate adaptive regression splines predicted the occurrence of individual species on each island. Principal component analysis recognised differences between Zygoptera and Anisoptera, but members of the two suborders have similar occurrences on islands, and island occurrence is determined mostly by species' frequencies at source and by their degree of generalism. Island species predicted correctly to occur on islands showed opposite characteristics to species unpredicted to occur and being present. The similarity pattern highlighted by turnover (Simpson index) is clearer than that obtained by non-partitioned beta diversity (Sørensen index). In fact, indicator value analyses revealed more indicator species for the Simpson compared to Sørensen index, and indicator species from islands where unpredicted to occur by impoverishment analysis. This suggests that island species predicted absent determine most of an island's turnover pattern, thus encompassing fundamental biogeographic information. Due to their absence on nearest sources, they are also at higher risk of extinction, and deserving of special conservation effort." (Authors)] Address: Dapporto, L., Centre for Ecology, En-

vironment and Conservation, Dept of Biological and Medical Sciences, Oxford Brookes University, Headington, Oxford, OX3 0BP, UK. E-mail: leondap@gmail.com

14162. Holuša, O.; Holušová, K. (2014): Could an active public recreation have an impact to populations of some insects in forest ecosystem - case of forest dragonflies. In: Fialová, J. & Pernicová, D. [eds.]. Public recreation and landscape protection – with man hand in hand? Conference proceeding. 5th – 6th May 2014, Křtiny. Department of Landscape Management FFWT, Mendel University in Brno: 75-79. (in English, with Czech summary) ["Among the ways of modern public recreation include horse-riding in the forests or stream climbing in mountain streams and gorges. Both of these activities are often operated outside the marked trails in the forests, trough forest springs or watercourses respectively. There are described cases of this type of recreation in forests in the Moravskoslezské Beskydy Mts. in relation to populations of forest species of dragonflies. Among the right forest species of dragonflies in Central Europe include species of the genus *Cordulegaster*. *C. bidentata* is the most abundant species in the forests of central Europe in the hills and mountains, which inhabits forest springs and streams. In some cases, the paths (trails) routed through these habitats. The case, horse-riding in forests with direct impact to larvae of *C.r bidentata*, has been recorded in the study of bionomics rheobiont dragonfly species. A one-time passage of horses is not destructive, but repeated ride on the same path is dangerous. Repeated passage of horses causes physical destruction of habitat i.e. trampling of sediments in shallow pools, where larvae are concentrated, but also direct trampling of larvae. Negative impact is also the chemical pollution of water excrement that is left in large quantities in the habitats. Threat increases during the emergency of larvae i.e. from May to June, when larvae dwell in bank parts and are sensitive to any interference with the habitat or contact. Repeated recreation outside the marked paths, still on the same trails, is becoming an important negative factor in the threat of forest habitats springs and insect populations." 14163. Hudu, F. (2014): What is the phonological word in Dagbani? A positional faithfulness account. *Ghana Journal of Linguistics* 3.1: 1-44. (in Dagbani, nasal place assimilation, vowel harmony, underspecification, positional faithfulness) ["This paper offers a phonological diagnostic for defining the word in Dagbani, a Gur language of Ghana. It shows that a morphological unit that constitutes a complete word blocks contrast-neutralising phonological processes from target segments within its boundaries when triggered across its boundary. In sub-word units, these processes (e.g. nasal place assimilation, vowel harmony, segmental deletion) apply to target sounds

without restrictions. The result is the maintenance of contrast in words and neutralisation of contrast in sub-words. The paper further argues that the asymmetrical application of these rules is an indication of a morphological strength distinction between the word as a strong position where segments are fully specified for phonological features, and the sub-word domain as a non-privileged position where segments may be underspecified for features. A formal analysis of the asymmetry is presented using the theory of positional faithfulness within the framework of Optimality Theory. ... Another such example is the word *sá-á pá?-á* which literally means 'rain's wife' but actually means 'dragonfly'. The point of these comparisons is that, while compounds sometimes convey such non-compositional meanings, complex words are compositional in meaning." (Author)] Address: Hudu, F., Department of Linguistics, School of Languages, University of Ghana, Legon, Accra, Ghana

14164. Ikomi, R.B.; Arimoro, F.O. (2014): Effects of recreational activities on the littoral macroinvertebrates of Ethiopie River, Niger Delta, Nigeria. *Journal of Aquatic Sciences* 29(1): 155-170. (in English) ["Littoral macroinvertebrate assemblages at four stations in Ethiopie River, Nigeria corresponding to different catchment land uses and recreational activities were sampled from October 2011 to May 2012 using kick sampling technique along with physico-chemical water parameters. The waters of Ethiopie River were in general, transparent, acidic with low pH values ranging from 4.6 to 6.4, reasonably well oxygenated (4.4-6.8 mg/L), of low conductivity (<38.0 μScm^{-1}) except in Station 2 where conductivity reached up to 47.2 μScm^{-1} Ephemeroptera, Plecoptera and Trichoptera dominated the headwater stations, whereas Coleoptera, Oligochaeta and Chironomidae dominated recreational sites. Significant relationships were recorded between physico-chemical parameters: conductivity, BOD, temperature, and nutrients and occurrence of specific taxa, mainly *Neoperla*, *Caenis*, *Baetis*, *Enallagma*, *Gyrinus*, *Leptonema*, *Rhematobates* and *Chironomus*. Distribution of organic matter, macrophyte cover, substratum texture, recreational activities and current velocity accounted for variations in species composition, taxonomic richness and total abundance at four stations sampled. Significant changes in macroinvertebrate assemblages were primarily due to changes in water quality. Littoral macroinvertebrate communities proved to be good indicators of water quality and should be used as bioindicators in long-term monitoring of this river." (Authors)] Address: Arimoro, F.O., Applied Hydrobiology Unit, Department of Biological Sciences, Federal University of Technology, P.M.B. 65, Minna, Nigeria. E-mail: fran-sarimoro@yahoo.com

14165. Ishida, S.; Kadoya, T.; Takamura, N. (2014): An integrated indicator of biodiversity in agricultural ponds: Definition and validation. Integrative observations and assessments. *Ecological Research Monographs* 2014: 295-310. (in English) ["One of the promising approaches

to monitoring biodiversity is assessing the status of pressures driving the biodiversity state. To achieve this, we need to identify the principal pressures that cause simultaneous biodiversity loss across taxonomic groups and clarify how multiple pressures act synergistically or at least simultaneously to decrease biodiversity in the focal ecosystem. Here, we introduce a framework for an integrated biodiversity indicator that takes into consideration the estimated relative importance of multiple pressures. The indicator is defined as a function of the pressure(s) and is parameterized to explain a number of individual states of biodiversity. We showed that the framework can be successfully applied to a real ecosystem, a series of 64 agricultural ponds. We focused on macrophytes, Odonata, and benthic macroinvertebrates as the individual states of biodiversity of the ponds and on three types of pressure: eutrophication, habitat destruction, and invasive alien species. We then evaluated the relationships among pressures with direct effects and the individual states of biodiversity and used a hierarchical Bayesian approach to calculate the integrated biodiversity indicator. We found that the integrated indicator could explain the behaviors of several individual states of biodiversity. To demonstrate the applicability of our approach, we adapted the integrated indicator to another dataset of 35 different agricultural ponds in which the integrated indicator was calculated using the relative importance of multiple pressures estimated from the previous 64-pond study. We found that we could successfully extrapolate the integrated indicator to the 35 agricultural ponds. These results demonstrate the advantages of the framework in providing a more practical method for assessing biodiversity in freshwater lentic environments and in quantifying the relative importance of the major threats to biodiversity to prioritize strategies in conservation planning and policy making." (Authors)] Address: Kadoya, T., 4. Center for Environmental Biology and Ecosystem Studies, National Institute for Environmental Studies, Ibaraki, Japan. E-mail: kadoya@nies.go.jp

14166. Ishiyama, N.; Akasaka, T.; Nakamura, F. (2014): Mobility-dependent response of aquatic animal species richness to a wetland network in an agricultural landscape. *Aquatic Sciences* 76: 437-449. (in English) ["Management of wetland connectivity is important for biodiversity conservation. In the modern agricultural landscape, the natural connections between floodplain wetlands have been greatly altered. Agricultural ditches and channelized streams are widely distributed in floodplains, which may contribute to the maintenance of wetland connectivity and biodiversity. To determine how these watercourse networks affect wetland biodiversity, we examined the relationship between the species richness of aquatic animals and wetland connectivity, with a special focus on species mobility. From July to August 2011, fish and aquatic insects were collected from 24 wetlands in northern Japan. To determine the degree of wetland connectivity, we assessed the relative importance of individual wetlands in maintaining the entire wetland network using two connectivity indi-

ces: hydrologic connectivity via watercourses and spatial connectivity defined as Euclidian distances between wetlands using graph theory. We found that only high mobility groups of both taxa could enhance species richness in either a hydrologic (fish) or spatial (insect) wetland network. The species richness of insects with high-flying ability was found to increase as spatial connectivity increased. Furthermore, the species richness of fish with high-swimming ability was positively influenced by hydrologic connectivity, most likely because highly mobile species were able to reach suitable habitats and migrate from source populations in a wetland network owing to their good mobility. Our findings indicate that hydrologic network is important for maintaining biodiversity as well as spatial connectivity. It is important to focus conservation efforts on key wetlands with high hydrologic and spatial connectivity in future wetland management." (Authors) The following odonate species were assessed according to their mobility: *Sympecma paedisca*, *Lestes sponsa*, *Copera annulata*, *Coenagrion ecomutum*, *C. lanceolatum*, *Enallagma boreale circumlatum*, *Erythromma humerale*, *Paracerion hieroglyphicum*, *Somatochlora japonica*, *S. viridiaenea*, *S. alpestris*, *Cordulia amurensis*, *Epithea bimaculata sibirica*, *Libellula quadrimaculata asahinai*, *Orthetrum albistylum speciosum*, *Sympetrum croceolum*, *S. eroticum eroticum*, *S. frequens*, *S. infuscatum*, *Aeshna nigroflava*, *Anax parthenope*, and *Trigomphus melampus*.] Address: Ishiyama, N., Department of Forest Science, Graduate School of Agriculture, Hokkaido University, Kita 9 Nishi 9, Kita-ku, Sapporo 060-8589, Japan. 14167. Jacquemin, S.J.; Pyron, M.; Allen, M.; Etchison, L. (2014): Wabash River Freshwater Drum (*Aplodinotus grunniens*) diet: Effects of body size, sex, and river gradient. *Journal of Fish and Wildlife Management* 5(1): 133-140. (in English) ["The objectives of this study were to describe the diet of freshwater drum (*Aplodinotus grunniens*) in the Wabash River, USA with tests for diet variation with body size, sex, and longitudinal river gradient. We used a multivariate ordination approach (nonmetric multidimensional scaling) to describe drum diet combined with a generalized linear model to test for covariation of diet with body size, sex, and river gradient. *Hydropsychidae* (Trichoptera, caddisfly larvae), *Pleuroceridae* (Gastropoda), and *Heptageniidae* (Ephemeroptera, mayfly larvae) were the most consumed prey items (~75% of overall diet). Among all freshwater drum, *Hydropsychidae*, *Pleuroceridae*, and *Heptageniidae* were present in 69%, 23%, and 38% of stomachs, respectively. Freshwater drum diets were similar along an upstream-downstream river gradient spanning 350 river km, but varied with body size and sex. Small- and medium-sized fish tended to consume more Diptera and annelids compared to the largest individuals which fed on molluscs and crayfish. With control for body size, the diets of male individuals were composed of more Diptera (*Chironomidae*) and annelid prey items compared with female individuals whose diet included more molluscs and crayfish. Overall, we interpret the lack of dietary turnover in freshwater

drum with Wabash River longitudinal gradient as evidence of diet specialization. Alternatively, we propose that a potential dietary - river gradient signal may be diluted as a function of increased freshwater drum longitudinal movements." (Authors) 0.66 % of the diet are Gomphidae, and a few Aeshnidae and Zygoptera.] Address: Jacquemin, S., Dept of Biological Sciences, Wright State University – Lake Campus, Celina, Ohio 45822, USA. 14168. Janssens, L.; Stoks, R. (2014): Chronic predation risk reduces escape speed by increasing oxidative damage: A deadly cost of an adaptive antipredator response. *PLoS ONE* 9(6): e101273. doi:10.1371/journal.pone.01-01273: 6 pp. (in English) ["Prey organisms evolved a multitude of plastic responses to avoid being eaten by predators. Besides the evolution of plastic morphological responses to escape predation, prey also evolved a set of physiological stress responses to avoid dying because of chronic predator stress per se due to disruption of cellular homeostasis. As physiological stress theory predicts increased energy consumption and the inhibition of essential nonemergency body functions, we tested whether chronic predation risk may increase oxidative damage thereby generating negative effects on escape performance. Specifically, we evaluated whether predation risk reduces escape swimming speed in damselfly larvae (*Coenagrion puella*) and whether this operates through stress-associated increases in oxidative damage. Counterintuitively and in contrast with many empirical studies, chronic predation risk decreased escape performance. This is however entirely consistent with the expectation of it being a long-term cost of responding to predation risk (e.g. by increasing respiration or upregulating the stress protein levels). The decreased swimming speed could be explained by an increased oxidative damage to proteins, thereby providing one of the poorly studied ecological links between oxidative damage and whole-animal performance. This likely widespread, understudied cost of chronic predation risk may provide an important pathway of non-consumptive predator effects on prey population dynamics. Moreover, it could play an evolutionary role by acting as a selective force causing prey organisms to adjust the magnitude of the physiological stress response and should be considered when evaluating life history trade-offs thought to be mediated by oxidative damage." (Authors)] Address: Janssens, Lizanne, Laboratory of Aquatic Ecology, Evolution and Conservation, University of Leuven, Leuven, Belgium. E-mail: lizanne.janssens@bio.kuleuven.be

14169. Jara, F.G. (2014): Trophic ontogenetic shifts of the dragonfly *Rhionaeschna variegata*: the role of larvae as predators and prey in Andean wetland communities. *Annales de Limnologie* 50(2): 173-184. (in English) ["Body size strongly influences the type and strength of species interactions. Animals with complex life cycles, such as dragonflies, usually go through different stages that include a variation in body size and may involve shifts in

their trophic position in the food web. This investigation analyzes the position of the dragonfly *Rhionaeschna variegata*, in the food web according to its body size, in Andean wetland communities of Northwestern Patagonia (Argentina). The phenology of *R. variegata* larvae and their potential intraguild predators were studied in wetlands with different hydroperiods. Under controlled experimental conditions, feeding trials were performed to assess the effect of *R. variegata* on the survivorship of different types of prey. The effects of cannibalism and intraguild predation (IGP) on the survivorship of the small larvae of *R. variegata* were investigated with and without alternative prey as well as different sympatric predators. The phenology of *R. variegata* and intraguild predators differed among wetlands. The feeding trials showed that *R. variegata* has a significant effect on the survivorship of invertebrate and vertebrate prey. Cannibalism increased with body size in odonate larvae. The survivorship of small- and medium-sized larvae was mainly affected by the presence of larger predators such as belostmatids. The field and experimental data show that the effect of IGP and cannibalism is affected by the cohort dynamics of *R. variegata*. Body size in *R. variegata* determines the strength of its interaction with other components of the community." (Author)] Address: Jara, F.G., Laboratorio de Fotobiología, Instituto de Investigaciones en Biodiversidad y Medioambiente (INIBIOM-CONICET), Quintral 1250, San Carlos de Bariloche 8400, Río Negro, Argentina. 14171. Jonsson, M.; Fick, J.; Klaminder, J.; Brodin, T. (2014): Antihistamines and aquatic insects: Bioconcentration and impacts on behavior in damselfly larvae (Zygoptera). *Science of the Total Environment* 472: 108-111. (in English) ["Highlights: •Exposure to dilute concentrations of antihistamines altered damselfly behaviour. •Damselfly larvae showed substantial bioconcentration of antihistamines. •Our results highlight the need to study pharmaceutical effects on aquatic insects. •Behavioural assays can be useful for studying non-lethal effects of pharmaceuticals. Because aquatic insects use histamines as neurotransmitters, adverse impacts on aquatic insects living in aquatic environments that receive antihistamines with wastewater effluent are plausible. In this study, we

exposed damselfly larvae to low concentrations of two commonly used antihistamines (Hydroxyzine and Fexofenadine, 360 ± 42 and 2200 ± 43 ng l⁻¹, respectively), and recorded damselfly larvae behaviour before and after exposure. Further, after the second set of behavioural assays was performed, we quantified bioconcentration of the antihistamines in the damselfly bodies. Our results showed significant changes in damselfly behaviour following antihistamine exposure. After Hydroxyzine exposure, the damselfly larvae became less active, and they showed reduced fleeing response (i.e. increased boldness) after being exposed to Fexofenadine, the latter also being significantly different from the non-exposed (control) individuals. Further, we found high levels of bioconcentration in the damselflies; Hydroxyzine showed an average bioconcentration factor (BCF) of 2000. As such, our results indicate that low concentrations of antihistamines can have sub-lethal effects on aquatic insects manifested as behavioural changes, and that bioconcentration of these substances can be high. Therefore, the need to investigate the impact of emergent aquatic contaminants also on aquatic insects, and on behaviours that are of ecological importance, is further highlighted." 14176. Kaunisto, K. (2014): Host parasite interactions in damselflies. From individuals to populations. Doctoral dissertation (monograph). Department of Biology, Zoological Museum. *Annales Universitatis Turkuensis A II* 291: 24 pp. (in English) ["The main goal of this thesis is to increase understanding on evolutionary and ecological factors that have contributed to differences in parasite numbers in insects. Furthermore, the thesis addresses the effects of parasites on their hosts. The most important findings were: *Coenagrion hastulatum* immune response to artificial pathogen increased with increasing parasite numbers (Article I). Marginal, more isolated *C. hastulatum* populations on the edge of distribution have fewer parasites when compared to distribution's core populations (Article II). *Calopteryx splendens* individuals with higher homozygosity have more parasites, however, the rate of homozygosity did not differ between populations (Article III). Parasite prevalence was affected by whether the host species occurred in allopatric or sympatric population: sympatric *C. splendens* populations with sister species *Calopteryx virgo* harbored more parasites (Article IV). Parasites were associated with the wing spot size, an ornament under sexual selection, and thus may play an important role in character displacement, i.e. the size of the wing spot (Article V). To conclude with, this thesis brings about new information on the parasite infection patterns in insects, proposing several factors to con-

tribute to these patterns, as well as it addresses the effects of parasites on their hosts, from individual to population level." (Author)] Address: Kaunisto, K.M., Section of Ecology, Department of Biology, University of Turku, FI-20014 Turku, Finland. E-mail: kkauni@utu.fi

14177. Khanfsi, T. (2014): Caractérisation des Mantodea dans différents biotopes de la région de Timimoun. Mémoires Ingénieur, Faculté des Sciences de la Nature et de la Vie, Département des Sciences Agronomiques, Université Kasdi Merbah Ouargla UKMO: 80 pp. (in French, with English and Arabian summaries) ["The diversity of Mantis in two natural and cultivated habitats in Timimoun is studied. Four species (*Blepharopsis mendica*, *Sphodromantis viridis*, *Iris oratoria*, *Iris deserti*) are inventoried in the herbaceous layer mainly after 12 months of exploration. The palmgrove has 3 species and Estivo - autumn period is the most conducive to catch. The Sex-ratio indicates a predominance of males, although the medium is moderately diversified (Simpson index $D = 0.65$). Morphological characterization and genitalia is made through a description and measurements. Diet of *Iris oratoria* contains Orthoptera (26.7%), Coleoptera and Odonata with (3.33 % each). *Iris deserti* consumes especially Diptera (33.33 %) and the same percentage of ants, Aranea, Dermaptera, Homoptera and with Collembola (16.6 %). The regime is moderately diversified (2.62 bits in the menu *Iris oratoria*, *Iris deserti* at 1.5 bits and 3.37 bits for *Blepharopsis mendica*). Prey size ranges from 2 to 20 mm. Trophic regime of 3 Mantids is insectivorous and generalist." (Author)] Address: not stated

14178. Kim, D.G.; Kang, H.J.; Baek, M.J.; Lee, C.Y.; Kim, J.G.; Bae, Y.J. (2014): Analyses of benthic macroinvertebrate colonization during the early successional phases of created wetlands in temperate Asia. *Fundamental and Applied Limnology / Archiv für Hydrobiologie* 184(1): 35-49. (in English) ["We quantified the colonization rate and pattern of benthic macroinvertebrate communities in 2 created small-sized wetlands (non-planted and planted) and a nearby older man-made wetland in Korea. We sampled benthic macroinvertebrates at monthly intervals and surveyed the vegetation dynamics every 2 months from May 2009 to October 2010. We determined the colonization rate using the newly adopted colonization index (CI), and evaluated the colonization pattern using multivariate analyses, including nonmetric multidimensional scaling (NMS) and indicator species analysis (ISPAN). As predicted, the species richness and diversity of benthic macroinvertebrates increased markedly in early successional phases in the 2 created wetlands, and initial planting accelerated colonization of benthic macroinvertebrate communities; in comparison, the older man-made wetland showed a more gradual increase. The CI (range 100–0) decreased over time in the created wetlands; this decrease was more rapid in the planted wetland than in the non-planted wetland. After 400 Julian days, the benthic macroinvertebrate community in the planted wetland showed 90 % similarity with

that in the older man-made wetland. The NMS results revealed that the colonization pattern of benthic macroinvertebrates differed significantly according to vegetation (non-planted versus planted [$p = 0.000$]), season ($p = 0.001$), and year ($p = 0.014$). The ISPAN results showed that the indicator species in the non-planted and planted wetlands were the burrowing mayfly (*Ephemera orientalis*) and *Ischnura asiatica*, respectively. Our findings demonstrate the validity of using the CI to quantify the colonization rate of benthic macroinvertebrate communities in typical small-sized temperate wetlands." 14179. Knorp, N.E.; Dorn, N.J. (2014): Dissimilar numerical responses of macroinvertebrates to disturbance from drying and predatory sunfish. *Freshwater Biology* 59(7): 1378-1388. (in English) ["(1) Disturbances caused by drying can eliminate fully aquatic organisms and alter wetland communities. However, the net effects of pulsed drying followed by re-wetting on populations of benthic macroinvertebrates with greater tolerance to drying have been poorly studied. (2) We quantified the population responses of two large macroinvertebrates, dragonflies (*Libellulidae*) and a crayfish (*Procambarus fallax*), to variable drying history and predatory sunfish (Family: Centrarchidae) in experimental subtropical wetlands. To simulate naturally occurring combinations of drying and sunfish presence, the experimental treatments included a drying and re-wetting sequence that either eliminated sunfish or did not, with a third treatment of continuously flooded conditions with sunfish present. (3) The activity of adult dragonflies was similar over all experimental wetlands, but larval density after 6 months was highest in continuously flooded wetlands (with sunfish) and some species (*Erythemis simplicicollis*, *Celithemis eponina*) were absent from wetlands that experienced drying. There was no evidence that sunfish limited larval density. (4) After 6 months, overall crayfish biomass was greatest in wetlands that had dried and lacked sunfish. Crayfish density was similar in all wetlands, but individual crayfish body mass (g) was greatest in wetlands that lacked sunfish. Because of sunfish predation, few crayfish survived to full juvenile size. In the presence of sunfish, drying did not affect crayfish biomass or individual body mass. (5) The abundance of libellulid dragonfly larvae was indirectly reduced by the drying. In wetlands where submerged vegetation was reduced by drying, we suggest that libellulid populations were limited by a small-bodied fish (*Gambusia holbrooki*). In contrast, survival of juvenile crayfish was directly limited by sunfish, and therefore, crayfish (but not libellulid) populations could be temporarily enhanced by drying events when and where sunfish populations are reduced." - 14183.** Kosterin, O.E. (2014): Odonata briefly observed on the islands of Bali and Lombok, Lesser Sundas, Indonesia, in the late February 2014. *International Dragonfly Fund Report* 74: 1-48. (in English) ["In the second half of February 2014, Odonata were searched for nine days on Bali and four days on Lombok, the western Lesser Sundas, Indonesia. One species, *Orthetrum chrysis* has been for the first time recorded for Bali and six species, *Nososticta emphylla*, *Idionyx murcia*, *Brachydiplax chalybea*, *Agrionoptera insignis*, *Neurothemis ramburii*, *Rhyothemis phyllis* have been for the first time recorded for Lombok. The previous literature concerning the two islands is analysed. To the moment, 55 Odonata species (3 unidentified) are known for Bali and 39 for Lombok, although the actual faunas of both islands are supposed to be equally rich, and further studies on Lombok are necessary. Odonata faunas of Bali and Lombok mirror each other in respect of high shares, 29 and 23%, of Odonata species ranging to the west and east of the two islands, respectively. Efficiency of Lombok Strait as a biogeographical boundary was estimated as high as 0.6, so Wallace Line is of importance for Odonata. Some diagnostic characters of *N. emphylla*, *N. ramburii*, *R. phyllis* *phyllis* and *Procordulia sambawana* and a taxonomical situation around *Prodasineura autumnalis* and *P. humeralis*, which is not justified biogeographically, are discussed. Short notes on habitats and assemblages of Odonata are added." (Author)] Address: Kosterin, O.E., Institute of Cytology & Genetics SB RAS, Acad. - 14184.** Kulijer, D. (2014): Odonata fauna of karst streams and rivers of South Herzegovina (Bosnia and Herzegovina, West Balkan). *International Dragonfly Fund - Report* 72: 1-50. (in English) ["Results of the odonatological survey in the Neretva River Basin in South Herzegovina karst region of Bosnia and Herzegovina conducted from April to August 2013 are presented. The area had been pre-assessed as insufficiently known in term of its Odonata fauna, but believed to be important habitat for several species of conservation concern, particularly *Coenagrion ornatum*, *Ceriatagrion tenellum*, *Calliaeschna microstigma*, *Lindenia tetraphylla* and *Cordulegaster heros*. Moreover, freshwater habitats of the region are increasingly threatened due to climate change and the habitat destruction due to infrastructure and hydroenergy production projects. The focus of the study was set on the streams and rivers in Neretva, Trebižat, Trebišnjica and Bregava river valleys, Hutovo blato wetland, Mostarsko blato, Dabarsko and Fatnicko polje. The survey resulted in 482 Odonata records of 49 species from 52 surveyed localities. Notable results include new distribution data on species of conservation concern, particularly six new localities of *C. ornatum*, nine of *C. microstigma* and five of *C. heros*. Comments on species of conservation concern and brief description of habitats at all surveyed localities are provided. New data on species of conservation concern are important for better conservation planning of dragonfly species and habitats in Bosnia and Herzegovina." (Author)] Address: Kulijer, D., National Museum of Bosnia and Herzegovina, Zmaja od Bosne 3, 71000 Sarajevo, Bosnia and Herzegovina. Email: dejan.kulijer@gmail.com
- 14185.** Kutcher, T.E. (2014): Biological indicators for assessing freshwater wetland condition in Rhode Island. *Dissertations and Master's Theses (Campus Access)*. Paper AAI1555662. <http://digitalcommons.uri.edu/dissertations/AAI1555662>: 98 pp. (in English) ["There is a growing need to identify assessment methods that can provide managers and researchers with a relative indication of wetland condition. Biological indicators (bioindicators) are considered to be the most effective and precise indicators of environmental condition. This study focuses on the develop-

ment of bioindicators based on the concept of species conservatism, or intolerance to human disturbance. In theory, the aggregate conservatism of a species assemblage should indicate the environmental quality of a natural area. In the first part of this study, I applied the conservatism concept to adult Odonata composition to create a novel bioindicator for open-canopy wetland systems. I used an extensive existing Odonata dataset to develop a conservatism-based Odonata index of wetland integrity and test it against rapid assessment and landscape-scale reference measures. The Odonata index was well predicted by both reference measures and showed no evidence of dependence on sampling effort, wetland size, or geomorphic class. My findings suggest that conservatism of adult Odonata averaged across species may provide a robust indicator of freshwater wetland integrity that is practical for wetland assessment. The conservatism concept is more typically applied to Floristic Quality Assessment (FQA), using vascular plant species. FQA index variants incorporating species richness, nativeness, and abundance have been empirically tested as indicators of freshwater wetland integrity, but less attention has been given to clarifying the mechanisms controlling FQA functionality; consequently, disagreement remains in identifying the most effective variant. In the second part of this study, I tested commonly-used FQA variants against landscape, rapid, and biological reference measures in open canopy wetlands. FQA variants incorporating species richness did not correlate with any reference measures and were influenced by wetland size and hydrogeomorphic class. In contrast, FQA variants disregarding species richness showed strong, monotonic relationships with all three reference measures, independent of wetland size and class. Incorporating non-native species improved performance over using only native species, and incorporating relative species abundance improved performance further. Non-richness variants responded linearly to individual and aggregate stresses, suggesting broad response to cumulative degradation, or decreasing integrity. These findings support the following recognized theories: aggregate plant species conservatism declines with increased disturbance; plant species richness increases with intermediate disturbance and increasing unit area; non-native species are favoured by human disturbances; and the proportional abundance of species is an important functional component of ecosystem health. This suggests that an abundance-weighted FQA variant incorporating non-native species and disregarding species richness should provide the most highly-relevant and effective FQA measure of ecological integrity for open-canopy vegetated wetlands." 14186. Laister, G.; Lehmann, G.; Martens, A. (2014): Exotic Odonata in Europe. *Odonatologica* 43(1/2): 125-135. (in English) ["Between 1991 and 2011, more than 1,000 adults of exotic odonate species were recorded from glasshouses of a wholesaler dealer of aquarium

plants near Wels, Austria. Twenty-three species could be identified to species level. All species were accidentally introduced as eggs or larvae. The majority are widely distributed and common southeastern Asian species. About 17 taxa are first recorded from Europe bringing the list of exotic Odonata in Europe to 41 taxa. These odonates are mainly introduced via aquarist trade and many species have emerged from home aquaria and glasshouses. Currently, tropical plants for aquarists are mainly imported to Europe from Singapore, Indonesia and Thailand, which suggests that the exotic Odonata originated in those countries. So far, the introduction of exotic Odonata species into Europe is not ecologically relevant because none of the introduced species have become established in the wild. However, this study will improve understanding of the significance of trading connections in establishing exotic species which could become invasive." (Authors)] Address: Laister, G., Hans-Hofmann-Ring 3, 4470 Enns, Austria. E-mail: glaister@aon.at

14187. Lee, S.-D.; Miller-Rushing, A.J. (2014): Degradation, urbanization, and restoration: A review of the challenges and future of conservation on the Korean Peninsula. *Biological Conservation* 176: 262-276. (in English) ["Highlights: •We review the current state of conservation challenges on the Korean Peninsula. •The peninsula hosts many endemic species and is critical for bird migrations. •Conservation challenges include development, pollution, and deforestation. •Biodiversity on the peninsula is poorly documented. Documentation is improving. •Conservation solutions include habitat restoration and conservation planning. Human history on the Korean Peninsula has left natural resource managers with a number of serious challenges regarding the preservation of biodiversity and ecosystem functions. The Korean Peninsula covers 222,403 km² and contains a mountainous interior, many islands, and biodiversity-rich coastal and marine areas. Biodiversity on the peninsula is not well documented, especially in North Korea, but the peninsula is estimated to host at least 100,000 species, and perhaps manyfold more. Roughly 6% of species identified to date are endemic, and among vertebrate species in South Korea, 29% of mammals, 14% of birds, 23% of freshwater fishes, 48% of reptiles, and 60% of amphibians are estimated to be at risk of extinction or have been extirpated from the peninsula. The situation is likely worse in North Korea. Species still occurring on the Korean Peninsula have survived near total deforestation of the landscape, heavy fishing, pollution, and, in South Korea, a period of rapid urbanization since the end of the Korean War in 1953. Conservation challenges are particularly dire in North Korea, where environmental degradation has impaired the country's ability to sustain agriculture, clean air and water, and other fundamental ecosystem services. Conservation faces significant challenges in South Korea, too, given the country's goal to continue to develop one of the world's most advanced and urbanized economies. Natural resource managers in both North and South Korea are pursuing large-scale restoration of forests, wetlands,

lakes and rivers, and coastlines as a primary conservation strategy. In addition, South Korea is aggressively developing a "green economy" and is hosting international environmental meetings, attempting to take a leadership role as a convener of innovative thinking in conservation. North and South Korea are also implementing more common land protection techniques, such as the creation of national parks and other protected areas. These protected areas include the exceptional case of the 100,000-ha (250 km × 4 km) Demilitarized Zone (DMZ) that forms the border between North and South Korea. The DMZ was not created for conservation reasons, but has provided an important refuge for many species. Other well-known protected areas include Jeju Island and Baekdu Daegan Mountain, both of which host many species important for conservation. Together, these conservation actions show promise and may allow the Korean Peninsula to preserve its biodiversity and regain some of its important ecosystem services. South Korea, in particular, provides an example for attempting to balance economic development and conservation in an area with a long history of human exploitation. North Korea is much farther behind in its conservation efforts, but is now beginning planning for large-scale restoration projects, which if implemented may help reverse its long trend of environmental degradation." (Authors) *Libellula angelina* was selected to demonstrate the situation of a species Critically Endangered globally. It was detected at just 18 localities in 2000, and is threatened by habitat destruction and degradation and predation by non-native species. A second dragonfly listed by IUCN is *Nehalennia speciosa*.] Address: Lee, S.-D., Department of Environmental Science and Engineering, GT5 Research Program, College of Engineering, Ewha Womans University, Seoul 120-750, Republic of Korea. 14189. Marino, J.A.; Holland, M.P.; Maher, J.M. (2014): Predators and trematode parasites jointly affect larval anuran functional traits and corticosterone levels. *Oikos* 123(4): 451-460. (in English) ["Non-consumptive predator effects may have dramatic consequences for host-parasite interactions by influencing the ability of prey items to avoid, resist, or tolerate infection. Both predators and parasites can affect host traits, such as growth rates and behaviour, and these effects may in part be mediated through shared physiological pathways (e.g. the glu-

cocorticoid stress hormone, corticosterone [CORT]). Here, we examined the effects of trematode parasites (*Digena*: *Echinostomatidae*) and predator (larval odonate; *Anax* spp.) exposure on larvae of two amphibian species (*Rana sylvatica* and *R. clamitans*) in laboratory experiments. First, we measured behaviour and CORT responses of tadpoles exposed to predator chemical cue in combination with parasite cue or under direct exposure to parasites. We then measured the combined effects of predator cue and parasite infection on survival and traits. Evidence for effects of parasite cue in our study was equivocal, but we found novel interactive effects of parasites and predators on larval frogs. Parasites and predators had antagonistic effects on CORT, behaviour, and morphology, and negative synergistic effects on development. In addition, parasite infection and predator cues additively reduced activity levels of both species and growth in wood frogs. Negative effects of parasite infection on survival and traits were dose-dependent for both species, although wood frogs generally experienced stronger effects of infection than green frogs. Our results emphasize the importance of considering effects of parasites as well as predators, since both can have strong effects on survival and the combination can have both additive and non-additive effects on key traits. These effects likely have important implications for amphibian population dynamics, community structure, and conservation." (Authors)] Address: Marino, J.A. Jr., Dept of Ecology and Evolutionary Biology, Univ. of Michigan, Ann Arbor, MI 48103, USA. E-mail: jamarino@umich.edu

14190. Marinov, M. (2014): An undescribed colour variation of female *Antipodochlora braueri* (Odonata: Corduliidae). *Odonatologica* 43(1/2): 105-114. (in English) ["Four *Antipodochlora braueri* (Selys, 1871) specimens (2 males, 2 females) were collected in the North Island of New Zealand. One female from the Taranaki region had a wing colouration previously unknown. The new colour variation is described here and is compared to what had been so far reported of female *A. braueri*. Important diagnostic features, such as appendages and vulvar scales, are illustrated. The colour variant female is also compared to the female of *Procordulia smithii* because of the similarity of the wing pattern, which had caused confusion in the past. A male collected together with the female had wings more tinged with yellow than other known males." 14191. McCauley, S.J.; Davis, C.J.; Werner, E.E.; Roberson, M.S. (2014): Dispersal, niche breadth, and population extinction/colonization ratios predict range size in North American dragonflies. *Journal of Animal Ecology* 83: 858-865. (in English) ["(1) Species' range sizes are shaped by fundamental differences in species' ecological

and evolutionary characteristics, and understanding the mechanisms determining range size can shed light on the factors responsible for generating and structuring biological diversity. Moreover, because geographic range size is associated with a species' risk of extinction and their ability to respond to global changes in climate and land use, understanding these mechanisms has important conservation implications. (2) Despite hypotheses that dispersal behaviour is a strong determinant of species range areas, few data are available to directly compare the relationship between dispersal behaviour and range size. Here, we overcome this limitation by combining data from a multi-species dispersal experiment with additional species-level trait data that are commonly hypothesized to affect range size (e.g. niche-breadth, local abundance, and body size, etc.). This enables us to examine the relationship between these species-level traits and range size across North America for fifteen dragonfly species. (3) Ten models based on a priori predictions about the relationship between species traits and range size were evaluated and two models were identified as good predictors of species range size. These models indicated that only two species' level traits, dispersal behaviour and niche breadth were strongly related to range size. The evidence from these two models indicated that dragonfly species that disperse more often and further had larger North American ranges. (4) Extinction and colonization dynamics are expected to be a key linkage between dispersal behaviour and range size in dragonflies. To evaluate how extinction and colonization dynamics among dragonflies were related to range size we used an independent data set of extinction and colonization rates for eleven dragonfly species and assessed the relationship between these populations rates and North American range areas for these species. (5) We found a negative relationship between North American range size and species' extinction to colonization ratios. Our results indicate that metapopulation dynamics act to shape the extent of species' continental distributions. These population dynamics are likely to interact with dispersal behaviour, particularly at species range margins, to determine range limits and ultimately species range sizes." 14192. McCormack, S.; Regan, E. (2014): *Insects of Ireland: An illustrated introduction to Ireland's common insect groups*. The Collins Press: 154 pp. (in English) ["Over 11,000 species of insects occur in Ireland but most are very small and escape notice. Identifying them accurately can be difficult or impossible. This comprehensive compact guide to over 120 of Ireland's most popular insects includes all Irish species of butterflies, bumblebees, dragonflies, ladybirds, grasshoppers and shield bugs. All are illustrated in colour with clear descriptions enabling accurate identification." (Publisher)] Address: not stated

14193. Melfi, J.; Leonardo, A.; Wang, Z.J. (2014): Roll dynamics in a free flying dragonfly (Abstract: F1.00015). *Bulletin of the American Physical Society, 67th Annual Meeting of the APS Division of Fluid Dynamics, Volume 59, Number 18, Sunday–Tuesday, November 23–25, 2014; San Francisco, California: (in English) [Verbatim: Dragonflies are capable of executing fast turning maneuvers. A typical free-flight maneuver includes rotations in all three degrees of freedom; yaw, pitch, and roll. This makes it difficult to identify the key changes to wing kinematics responsible for controlling each degree of freedom. Therefore we focus on a single motion; roll about the body longitudinal axis in a combined experimental and computational study. To induce rolling, a dragonfly is released from a magnetic tether while inverted. Both wing and body kinematics are recorded using multiple high speed cameras. The kinematics are replayed in a computer simulation of the flight, with forces and torques based on quasi-steady aerodynamics. By examining the effect of each kinematic change individually, we determine the key changes a dragonfly uses to both instigate, maintain, and end a rolling motion.]* Address: not stated

14194. Merkel-Wallner, G. (2014): *Insekten im Rainer Wald. Beiträge zur bayerischen Entomofaunistik 13: 1-65.* (in German, with English summary) [This is an overview of the known insects from the "Rainer Wald", a 250-acre hardwood floodplain forest in Danube valley near Straubing, Bavaria, Germany. On pages 8-10, 25 local Odonata species are listed and briefly discussed.] Address: Merkel-Wallner, Gisela, Bühläcker 3, 93444 Bad Krotzing, Germany

14195. Monroe, E.M.; Britten, H.B. (2014): Conservation in Hine's sight: the conservation genetics of the federally endangered Hine's emerald dragonfly, *Somatochlora hineana*. *Journal of Insect Conservation* 18: 353-363. (in English) ["*S. hineana* is distributed in discrete fen and wet meadow habitats over its range from Ontario, Canada, to Missouri, USA. Habitat destruction in the vicinity of Chicago, IL, and other areas lead to its designation as an US federal endangered species in 1995. Our main goal was to delineate the population genetic structure of the species within the northern recovery unit centered on the Door Peninsula in Wisconsin and the southern recovery unit in the Des Plaines River Valley near Chicago, IL. Sites on the Door Peninsula, WI, are in a matrix of agricultural development and second-growth forest and were used as a best available approximation of a pristine system for the dragonfly. We nondestructively sampled 557 adults and larvae from 16 sites in Illinois, Michigan, and Wisconsin from 2008 through 2011 and used ten microsatellite markers to estimate levels of genetic variability, and genetic structure. Mean allelic richness across all sites and years was 5.03 (± 0.64) and expected heterozygosity was 0.52 (± 0.032). Northern and southern recovery units as designated in the original recovery plan were genetically distinct. We delineated two genetic populations in the northern unit and three within the southern

including two disjunct sites." (Authors)] Address: Monroe, Emy, Department of Biology, University of South Dakota, 414 E. Clark St., Vermillion, SD, 57069, USA. E-mail: emymonroe@gmail.com

14196. Mourão, M.A.N.; Peixoto, P.E.C. (2014): Do morphological and physiological characteristics of males of the dragonfly *Macrothemis imitans* determine the winner of territorial contests? *Journal of Insect Science* 14(89): 10 pp. (in English) ["Males of many animal species show intraspecific disputes for mating territories that range from displays without physical contact to physical fights with risk of injury. This variation motivated the proposition of different models that suggest possible rules used by rivals to decide the contest winner. To evaluate those models, it is necessary to identify how males behave during the fight and the individual attributes that determine their fighting ability (resource holding potential). For this, males of *M. imitans* were used to evaluate two hypotheses conditioned on the occurrence of physical contact during the fight: if the contests occur with physical contact, features related to size should determine male resource holding potential, and if males do not exhibit physical contact during the contests, features that confer greater endurance should determine resource holding potential. To assess these hypotheses, we collected males that had ownership of territories (resident males) and males that occupied the territory after we removed the resident males (substitute males). After the capture, the resident and substitute males were transferred to the laboratory for measurements of wing area, dry weight, thoracic muscle mass, and fat content. The results showed that resident males do not differ in any measured trait from substitutes. Because the fights occur with physical contact, it is intriguing that resident males do not possess higher fighting capacity than intruders. Perhaps physical contact does not incur high costs during the fight, and other asymmetries, such as motivation associated with prior residency of the disputed territory, determine the contest winner." 14197. Na, Y.; Sun, C.; Li, T.; Li, Y. (2014): The insect oviposition firstly discovered on the Middle Jurassic Ginkgoales leaf from Inner Mongolia, China. *Acta Geologica Sinica (English Edition)* 88(1): 18-28. (in Chinese, with English summary) ["Although the evidence of insect oviposition on plant organs has been reported from the late Paleozoic to the Miocene, record from the middle Jurassic is still blank. This paper reports a significant evidence of insect oviposition on plant leaf from the middle Jurassic for the first time. The ovipositional scar is distributed on the abaxial surface of *Sphenobaiera* leaf (Ginkgoales) from the middle Jurassic Daohugou Formation of Inner Mongolia, China. A new ichnospecies *Paleoovoidus venustus* sp. nov. is described. The scar is elliptic to oval, arranged in longitudinal rows between leaf veins with al-

most regular distance, with its long axis paralleling to the leaf venation. This discovery adds new information to the morphology of insect endophytic oviposition probably produced by Odonata existed in a terrestrial ecosystem ~165 Ma ago. The new materials also provide important data for the study of insect reproductive biology, plant-insect interaction and coevolution, as well as understanding the paleoclimate and palaeoenvironment during that time in northeast China." 14203. Nilsson-Örtman, V.; Stoks, R.; Johansson, F. (2014): *Competitive interactions modify the temperature dependence of damselfly growth rates*. *Ecology* 95: 1394 -1406. (in English) ["Individual growth rates and survival are major determinants of individual fitness, population size structure and community dynamics. The relationships between growth rate, survival and temperature may thus be important for predicting biological responses to climate change. Although it is well known that growth rates and survival are affected by competition and predation in addition to temperature, the combined effect of these factors on growth rates, survival and size structure has rarely been investigated simultaneously in the same ecological system. To address this question, we conducted experiments on the larvae of two species of damselflies and determined the temperature-dependence of growth rates and survival and the resulting cohort size structure under three scenarios of increasing ecological complexity: no competition, intraspecific competition and interspecific competition. In one species, the relationship between growth rate and temperature became steeper in the presence of competitors whereas that of survival remained unchanged. In the other species, the relationship between growth rate and temperature was unaffected by competitive interactions but survival was greatly reduced at high temperatures in the presence of interspecific competitors. We also found that the combined effect of competitive interactions and temperature on cohort size structure differed from the effects of these factors in isolation. Together, these findings suggest that it will be challenging to scale up information from traditional, single-species laboratory studies to the population and community level." 14204. Norma-Rashid, Y.; Saleeza, S.N.R. (2014): *Ecofriendly control of three common mosquito larvae species by Odonata nymphs*. *Basic and Applied Aspects of Biopesticides 2014*: 235-243. (in English) ["This chapter revealed the efficacy of three predominant dragonfly species found in a natural population where the survey of mosquito population was conducted. Nymphs of dragonflies belonging to family *Libellulidae*, *Neurothemis fluctu-*

ans, *Orthetrum sabina*, and *Orthetrum chrysis*, were used as predators on the IV instar of mosquito larvae, *Aedes albopictus*, *Aedes aegypti*, and *Culex quinquefasciatus*. The daily feeding rates varied among predators and mosquito species. The mean numbers of mosquito larvae consumed by the predators were different between the mosquito species. *Aedes aegypti* was the most preferred prey for *Orthetrum sabina* and *Neurothemis fluctuans*. However, *Orthetrum chrysis* consumed more of *Culex quinquefasciatus* in contrast to other prey species. Feeding activities peaked during light-on in contrast to light-off. The results of variation factors that influenced the predation activities were significant and further discussed in this chapter. The factors that were assessed in the experiments included the water volume, predator species, predator density, and prey density and species. This chapter lends support to the potential use of Odonata species as an eco-friendly method of mosquito population eradication." (Authors)] Address: Y. 14208. Nyffeler, M.; Pusey, B.J. (2014): Fish predation by semi-aquatic spiders: A global pattern. *PLoS ONE* 9(6): e99459. doi:10.1371/journal.pone.0099459: 21pp. (in English) ["More than 80 incidences of fish predation by semi-aquatic spiders – observed at the fringes of shallow freshwater streams, rivers, lakes, ponds, swamps, and fens – are reviewed. We provide evidence that fish predation by semi-aquatic spiders is geographically widespread, occurring on all continents except Antarctica. Fish predation by spiders appears to be more common in warmer areas between 40°S and 40°N. The fish captured by spiders, usually ranging from 2–6 cm in length, are among the most common fish taxa occurring in their respective geographic area (e.g., mosquitofish [*Gambusia* spp.] in the southeastern USA, fish of the order Characiformes in the Neotropics, killifish [*Aphyosemion* spp.] in Central and West Africa, as well as Australian native fish of the genera *Galaxias*, *Melanotaenia*, and *Pseudomugil*). Naturally occurring fish predation has been witnessed in more than a dozen spider species from the superfamily Lycosoidea (families Pisauridae, Trechaleidae, and Lycosidae), in two species of the superfamily Ctenoidea (family Ctenidae), and in one species of the superfamily Corinnoidea (family Liocranidae). The majority of reports on fish predation by spiders referred to pisaurid spiders of the genera *Dolomedes* and *Nilus* (>75% of observed incidences). There is laboratory evidence that spiders from several more families (e.g., the water spider *Argyroneta aquatica* [Cybaeidae], the intertidal spider *Desis marina* [Desidae], and the 'swimming' huntsman spider *Heteropoda natans* [Sparassidae]) predate fish as well. Our finding of such a large diversity of spider families being engaged in fish predation is novel. Semi-aquatic spiders captured fish whose body length exceeded the spiders' body length (the captured fish being, on average, 2.2 times as long as the spiders). Evidence suggests that fish prey might be an occasional prey item of substantial nutritional importance." (Authors) The publication includes a small compilation of studies with information on estimated fresh weight (g/prey item) and caloric value (kJ/g dry weight) of Odonata used by semi-aquatic spiders: Fresh weight: 0.1–1.5; Caloric value: 21–22.] Address: Nyffeler, M., Section of Conservation Biology, Dept of Environmental Sci., Univ. Basel, Basel, Switzerland. E-mail: martin.nyffeler@unibas.ch

14209. Obata, A.; Shinohara, S.; Akimoto, K.; Suzuki, K.; Seki, M. (2014): Aerodynamic bio-mimetics of gliding dragonflies for Ultra-Light Flying robot. *Robotics* 3(2):

163-180. (in English) ["A detailed investigation including a low-speed flow study is presented on the development of ultra-light dragonfly mimetic flying robots with a focus on the dragonfly's remarkable gliding capability. It is revealed that the dragonfly's corrugated wing structure and cruciform configuration provide superior flying characteristics for fixed wing robots in low Reynolds number flight. It was also found that the dragonfly configuration has additional merit in its compatibility with propellers or high lift devices. This combination with such classic aero-engineering makes possible robots with broader flight envelope than conventional fixed-wing flying robots." 14210. O'Connor, J.H. (2014): Manipulation of larval and winter habitat reveals potential effects of urbanization and climate change on Wood Frogs in Connecticut. Master's Theses, University of Connecticut: 69 pp. (in English) ["Runoff from urban development and agricultural activity increases sediment input and water turbidity in many aquatic systems. These factors are known to affect fish and invertebrate communities but effects on amphibians are poorly understood. Runoff can transport nitrogenous compounds, heavy metals, pesticides, and other pollutants in addition to sediment. Our goal was to isolate the effect of sediment input from these other potential aquatic stressors. We manipulated silt addition in mesocosms to determine if sediment input affected survival, growth, or development of larval wood frogs (*Lithobates sylvaticus*). We also crossed our silt addition treatment with a predator (*Libellula cyanea*) presence treatment to assess interactive effects of multiple stressors. We found no effect of silt addition or predator presence on survival. Furthermore, addition of a large amount of silt during the early larval period resulted in earlier metamorphosis ($F_{1,30} = 5.111$, $p = 0.031$) at a larger size ($F_{1,30} = 36.244$, $p < 0.001$), traits generally viewed as positive for population dynamics. Non-lethal predator presence did not affect either mass at or time to metamorphosis. Results suggest that suspended sediment by itself is not directly harmful to wood frogs and potentially may serve as an additional food resource. Manipulating turbidity in mesocosms has advantages over studying turbidity in natural systems because treatments can be controlled and replicated sufficiently. Future research should investigate the relationship between sediment organic content and tadpole growth and survival and the interaction between water turbidity and other wetland stressors." (Author)] Address: O'Connor, J.H., Dept of Natural Resources and the Environment, University of Connecticut, Storrs, CT, USA. E-mail: jason.h.oconnor@uconn.edu

14211. Orlofske, S.A.; Jadin, R.C.; Hoverman, J.T.; Johnson, P.T.J. (2014): Predation and disease: understanding the effects of predators at several trophic levels on pathogen transmission. *Freshwater Biology* 59(5): 1064-1075. (in English) ["Predators can directly and indirectly

influence host-parasite interactions by consuming infected individuals, by removing infectious parasite stages and by changing host traits (e.g. behaviour). Because such effects can affect infection positively or negatively, understanding the net effects of predation on pathogen transmission under natural conditions is important. We conducted a mesocosm experiment to examine the effects of predators on interactions between tadpole hosts (*Pseudacris regilla*) and trematode parasites (*Ribeiroia ondatrae*). We manipulated the presence of (non-lethal, i.e., caged) predators of tadpoles (dragonfly larvae) and (potentially lethal) parasite predators (damselfly larvae) to evaluate their individual and combined effects on host infection. We expected that dragonflies would reduce tadpole activity and thereby increase parasite infection through a reduction in antiparasite behaviour. Because damselflies can consume parasites in the laboratory, we predicted that damselflies would lower infection by consuming parasites before they infected tadpoles. Our goal was to evaluate the net consequences of these predator-mediated effects for host/prey infection. The presence of caged dragonflies reduced tadpole activity, resulting in a ~50% increase in average infection load compared to treatments without predators. In contrast to our prediction that damselflies would reduce infection, damselflies elicited behavioural and morphological changes in hosts similar to dragonflies, with a comparable increase in parasite transmission. Thus, predator-mediated effects were evident predominantly through changes in host/prey behaviour, rather than through changes in the abundance of parasites. The lack of a direct effect of predators on infection (i.e. via consumption of parasites) could be the result of the presence of alternative prey (zooplankton) or a mismatch in timing between visual predators feeding during the day and parasites released from the first intermediate host and infecting amphibians at night. The presence of predators also stimulated morphological defences in their tadpole prey, including increased tail and body depth. Interestingly, we found that parasite infection also induced morphological changes in tadpole tail and body depth, similar to changes produced by (non-lethal) cues from predators. Parasites caused malformations in tadpoles, but there were no effects on tadpole growth or development from either parasites or predators. This research has key implications for linking predation and infectious disease in aquatic ecosystems. Our results emphasise the importance of indirect effects of predators on infection and highlight possible trade-offs in mitigating the concurrent risks of predation and disease. Parasites can also alter host morphology through trait-mediated effects similar to predators, supporting a broader inclusion of parasites in the study of the ecology of natural enemies." 14216. Piersanti, S.; Frati, F.; Conti, E.; Rebora, M.; Salerno, G (2014): The sense of smell in Odonata: An electrophysiological screening. *J. Insect Physiol.* 70: 49-58. (in English) ["Volatile chemicals mediate a great range of intra- and interspecific signalling and information in insects. Olfaction has been widely investigated mostly in Neoptera while the knowledge of this sense in most basal insects such as Paleoptera (Odonata and Ephemeroptera) is still poor. In the present study we show the results of an electrophysiological screening on two model species, *Libellula depressa* and *Ischnura elegans*, representatives of the two Odonata suborders Anisoptera and Zygoptera, with the aim to deep the knowledge on the sense of smell of this insect order. The antennal olfactory sensory neurons (OSNs) of these two species responded to the same 22 compounds (out of 48 chemicals belonging to different functional groups) encompassing mostly amines, carboxylic acids or aldehydes and belonging to green leaf volatiles, vertebrate related volatiles and volatiles emitted by standing waters bacteria. The properties of Odonata OSNs are very similar to those of ionotropic receptors (IRs) expressing OSNs in other insects." 14217. Quisil, J.C.; Nuñez, O.M.; Villanueva, R.T. (2014): Impact of mine tailings on the species diversity of Odonata fauna in Surigao del Sur, Philippines. *Journal of Biodiversity and Environmental Sciences* 5(1): 465-476. (in English) ["Odonata is very sensitive to changes in habitat, making it a reliable bio-indicator of environmental health. This study was conducted to assess the impact of mine tailings on the species diversity of Odonata in Surigao del Sur, Philippines. Eight sampling sites were surveyed comprising four sites with mine tailings and four sites without mine tailings. Opportunistic sampling using sweep nets was conducted on August 24-27, 2013 and October 26-29, 2013. Eighteen species were documented belonging to sixteen genera and six families. Over-all endemism was low at 22%. Seven species were recorded under sub-order Zygoptera, and eleven under sub-order Anisoptera. Species diversity and evenness were significantly different between areas with mine tailings and those without. Sites without mine tailings had higher

abundance, species richness, and endemism than sites with mine tailings. Results indicate that mine tailings adversely affect species diversity of Odonata." 14219. Ramsey, A. (2014): Odonata to joy. *OneVoice* March 2014: 8. (in English) [Nevada, USA; Verbatim: Back in late September of last year, NNSS scientists guided visiting dragonfly specialists Neil McDonal and Bruce Lund on a one-day trip to the site to collect samples of the elaborately coloured insect. In total, the group visited sites in five regions of the NNSS. Bad weather, however, proved to be an obstacle. "Only four specimens were captured due to cold windy weather," said National Security Technolgtes biologist Paul Greger. "Fortunately, we were able to collect one new species for the site, the black fronted fork-tail. [*Ischnura denticollis*]" Working under the National Wildlife Refuge System, McDonal and Lund recently completed a regional study of Odonata - a division of carnivorous insect that includes the dragonfly and the smaller damselfly. They are seeking to build up on their research by sampling in areas that are farther north from their original southern Nevada study area. McDonal and Lund were able to identify nine Odonata species from an existing NNSS collection of Odonata archived in the 1990s. Additional field work is planned for 2014.] Address: not stated

14220. Ratna, O.P. (2014): Morphological characters and dietary diversity of Great Crested Canopy Lizard (*Bronchocela jubata* Dumeril & Bribon, 1837) along Opak riverside in Daerah Istimewa Yogyakarta. *Fakultas Biologo, Universitas Gadjah Mada, Yogyakarta*: 46 pp. (in Indonesian, with English summary) ["Java is one of the biggest island in Indonesia and divided into east, middle, and west regions. Each of them differ in landscapes, climates, and any other enviromental conditions. Those can lead to variation of animal characters on each regions. Biodiversity in Yogyakarta are very high. It is supported by various of ecosystems within the province. One of the riparian ecosystem in Yogyakarta is Opak River. It becomes a water source for animals live along the riverside, include for the herpetofauna *Bronchocela jubata*.

This insectivorous lizard has an important role in food chain within riparian ecosystem. This research was conducted to find out the morphological characters and dietary diversity of *B. jubata* at Opak riverside. VES (Visual Encounter Surveys) method was used for sampling. Then 60 morphological characters of each specimens were observed and measured. Specimens were identified based on Book of Identification and paratype specimens from Lembaga Ilmu Pengetahuan Indonesia (LIPI). All data were analyzed with NTSYSpc 2.1 to understand the similarity value of each individual. The ventriculus of each individual were preserved and then dissected. Food substances within ventriculus were observed using stereo microscope. The results showed that specimens of *B. jubata* at Opak riverside had more similarity with West Java specimens than with Sulawesi specimens. Similarity value of Opak specimens and paratype specimens from West Java was 62%. Whereas similarity of Opak specimens and paratype specimens from Sulawesi was just 54%. Specimens *B. jubata* at Opak riverside have observation of ventriculus contents showed that *B. jubata* mostly preyed on Insects from Order Hymenoptera, Lepidoptera, Odonata, Hemiptera, Orthoptera, and Coleoptera. Conclusion of this research, *B. jubata* at Opak riverside were similar with paratype specimens from West Java. *B. jubata*'s prey consist of 6 orders of insect, most of them were members of Order Odonata and Orthoptera." 14221. Ratti, J.; Vachtsevanos, G.J. (2014): Inventing a biologically inspired, energy-efficient Micro Aerial Vehicle. In: Kimon P. Valavanis, & George J. Vachtsevanos (eds.): *Handbook of Unmanned Aerial Vehicles*. Springer: 1385-1413. (in English) ["In recent years, research efforts have focused on the design, development, and deployment of unmanned systems for a variety of applications ranging from intelligence and surveillance to border patrol, rescue operations, etc. Micro aerial vehicles are viewed as potential targets that can provide agility and accurate small area coverage while being costeffective and can be easily launched by a single operator. The small size of MAVs allows such flight operations within confined space but the control effectors must provide sufficient maneuverability, while maintaining stability, with only limited sensing capability onboard the platform. To meet these challenges, researchers have long been attracted by the amazing attributes of biological systems, such as those exhibited by birds and insects. Birds can fly in dense flocks, executing rapid maneuvers with g-loads far in excess of modern fighter aircrafts, and yet never collide with each other, despite the absence of air traffic controllers. This chapter introduces a novel framework for the design and control of a micro air vehicle. The vehicle's conceptual design is based on biologically inspired principles and emulates a dragonfly (Odonata-Anisoptera). A sophisticated multilayered hybrid and linear/non-linear controller to achieve extended flight times and improved agility compared to other rotary and flapping wing MAV designs. The chapter addresses the design and control fea-

tures of the proposed QV design and gives an overview on the developmental efforts towards the prototyping of the flyer. The potential applications for such a high-endurance vehicle are numerous, including airdeployable mass surveillance in cluster and swarm formations. The disposability of the vehicle would help in battlefield deployment as well, where such a, MAV would be made available to soldiers for proximity sensing and threat level assessment. Other applications would include search and rescue operations and civilian law enforcement." (Authors)] Address: Ratti, J., Robotics & Intelligent Machines, TechJect Inc., Atlanta, GA, USA. 14222. Reborá, M.; Gaino, E.; Piersanti, S. (2014): The epipharyngeal sensilla of the damselfly *Ischnura elegans* (Odonata, Coenagrionidae). *Micron* 66: 31-36. (in English) ["Highlights: •No ultrastructural investigation has been performed so far on Odonata epipharynx. •We investigated the sensilla on the labrum of damselfly adults (*Ischnura elegans*). •On its ventral side the epipharynx shows sensilla (articulated hairs and small pegs). •The hairs, with a socket and a tubular body, have the structure of mechanoreceptors. •The pegs, with a tiny apical pore, have features typical of contact chemoreceptors. The knowledge on Odonata adult mouthparts sensilla is scanty and, notwithstanding the epipharynx in the labrum is considered an organ of taste, no ultrastructural investigation has been performed so far on this structure in Odonata. The labrum of the adult of *I. elegans* shows on its ventral side the epipharynx with sensilla represented by articulated hairs and by small pegs located at the apex of slightly raised domes. Under scanning and transmission electron microscope, the articulated hairs, with a well developed socket and tubular body, have the typical structure of bristles, the most common type of insect mechanoreceptors, usually responding to direct touch; the pegs, showing an apical pore together with a variable number of sensory neurons (from two to five), the outer dendritic segments of which show a dendrite sheath stopping along their length, have features typical of contact chemoreceptors." The distributions of *Aphylla theodorina* and *Caenis tenella* (Caenidae) are extended to the Yungas (both previously known for the NE of Argentina). New records are also included for: *Neoneura confundens*, *Anax amazili*, *Brachymesia furcata*, *Erythemis plebeja*, *Erythrodiplax melanorubra*, *E. nigricans*, *Macrothemis imitans imitans*, *M. musiva*, *Miathyria marcella* and *Micrathyria hesperis*,

Progomphus complicatus and *P. joergenseni*." (Authors)] Address: Rodríguez, J.S., Instituto de Biodiversidad Neotropical CONICET-UNT, Horco Molle, s/n, (4107), San M. de Tucumán. E-mail: josephum@hotmail.com

14224. Roh, C.; Gharib, M. (2014): Modulation of a flow field by dragonfly nymph valve kinematics (Abstract: R7.00003). *Bulletin of the American Physical Society*, 67th Annual Meeting of the APS Division of Fluid Dynamics, Volume 59, Number 18, Sunday–Tuesday, November 23–25, 2014; San Francisco, California: (in English) [Verbatim: Previously, we visualized a respiratory jet and a propulsive jet of a dragonfly nymph using laser induced fluorescence. A more quantitative measurement of the dragonfly nymph's underwater breathing was investigated using digital particle image velocimetry. Simultaneously, dragonfly's anal valve kinematics were recorded using high-speed videography. The result shows an active usage of the valve during exhalation and inhalation to modulate the flow field. Calculating a Lagrangian particle path by time integration of the velocity field showed that the exhaled fluid is not inhaled back. This result suggests that the anal valve modulation of the flow field prevents the rebreathing of the exhaled jet.] Address: not stated

14226. Ruokonen, T.J.; Karjalainen, J.; Hämäläinen, H. (2014): Effects of an invasive crayfish on the littoral macroinvertebrates of large boreal lakes are habitat specific. *Freshwater Biology* 59(1): 12-25. (in English) ["(1) Invasive crayfish are widely acknowledged to have negative effects on benthic food webs in lakes, but few studies have investigated such effects at wider spatial scales and in varying habitats under natural conditions. (2) We examined the effects of introduced signal crayfish (*Pacifastacus leniusculus*) on the macroinvertebrate assemblages of different habitats in two large boreal lakes. We evaluated whether the density, taxon richness and

species composition are altered by the non-native crayfish and whether the responses are similar for stony and vegetated habitats and across a depth gradient. We also studied the influence of crayfish on periphyton biomass at stony sites, as a potential link to changes in macroinvertebrate communities. (3) In both lakes, macroinvertebrate density was similar between crayfish and non-crayfish sites across the habitats and depths studied. However, macroinvertebrate taxon richness was significantly lower, and community composition was altered in the presence of crayfish at stony sites. No similar pattern was detected at vegetated sites or in deeper sublittoral areas. The amount of periphyton was similar regardless of the presence of crayfish, and no clear direct or indirect crayfish–periphyton interaction was detected. (4) Our results suggest that introduced signal crayfish can have negative effects on the littoral macroinvertebrates of large boreal lakes, but that these effects are habitat specific. Our findings highlight how the evaluation of possible effects of invasive species needs to be carried out comprehensively across different habitats and spatial scales if conclusions are to be robust." 14229. Sadeghi, S.; Dumont, H.J. (2014): Variation in the shape of the wings and taxonomy of Eurasian populations of the *Calopteryx splendens* complex (Odonata: Calopterygidae). *Eur. J. Entomol.* 111(4): 575-583. (in English) ["We used geometric morphometrics to determine variation in the morphology of the forewings of individuals in 20 populations of *Calopteryx splendens* s.l. in Eurasia and related these to the circum-specific taxonomy of this taxon. We found differences in shape, with the largest and smallest centroid size of the wings in adjacent northern (*orientalis*) and western (*intermedia*) populations in Iran, respectively, so isolation and relationship are not necessarily determined by distance, but often associated with the stream basin inhabited. The variation in wing shape, however, was much greater. with Populations at the eastern edge of the range (Tajikistan, Kyrgyzstan and East Kazakhstan) uniquely different. Oddly, no taxonomic name is associated with them, although they may be among the oldest representatives of the *splendens* complex. The European and Asian populations are in two separate clades. One of these includes insects with no to a medium-sized wing spot, which does not reach the tip of the wing (*waterstoni*-group), while the other includes insects with very broad wing spots, or, when short, it extends to the very tip of the wings and most females are androchrome (*ancilla* or *intermedia* group). Turkmenistan and northern Iranian population form a separate line inside this clade, which we equate with *Calopteryx orientalis*. South Albanian and Greek populations are in a separate branch corresponding to ssp. *balcanica*; two populations from Ireland and Italy form a branch that has no equivalent in traditional taxonomy, while *Calopteryx xanthostoma* was not identified by its wing shape. Understanding this multitude of phenotypes and the enormous amount of variation within certain populations but not in others becomes easy if one assumes there were two probable late Pleistocene waves of migration, the first of insects lacking spots that migrated east and westwards from the South Black Sea basin, the second, perhaps from the west Caspian, composed of heavily spotted insects with androchromic females. The hybridization between these two waves resulted in the current plethora of colour forms and accounts for why similar phenotypes may turn up independently in widely distant locations." 14231. Sánchez-Guillén, R.A.; Córdoba-Aguilar, A.; Cordero-Rivera, A.; Wellenreuther, M. (2014): Rapid evolution of prezygotic barriers in non-territorial damselflies. *Biological Journal of the Linnean Society* 113(2): 485-496. (in English) ["A central question in evolutionary biology concerns the accumulation of reproductive barriers during speciation. However, separating the reproductive barriers that have led to speciation from those that have secondarily accumulated (i.e. after initial divergence) is a widely recognized problem. Ideal candidate species for overcoming this problem are young species, where time for additional barriers to accrue has been limited. In the present study, we add to previous studies investigating the strength of reproductive barriers between the parapatric damselflies *Ischnura elegans* and *I. graellsii* by quantifying seven prezygotic barriers between the allopatric pairs of *I. elegans* and *I. genei*, as well as *I. graellsii* and *I. genei*. Specifically, we measured four premating (temporal, sexual, mechanical I, and mechanical II) and three postmating (oviposition success, fecundity, and fertility) barriers using experimental approaches and, for first time, we investigated the mechanisms causing mechanical isolation, which is the strongest reproductive barrier in ischnurans. The findings of the present study support the notion that premating barriers are generally strong and contribute significantly to total reproductive isolation in young lineages (65–98%), although they never solely lead to complete isolation. Asymmetry was generally stronger in premating than in postmating barriers, and was driven mostly through asymmetry in mechanical isolation, which is caused by morphological divergence of secondary sexual appendages. We found that barriers act multiplicatively in all species combinations tested, with the exception of sexual isolation, which was not detected. Our results are consistent with a recent allopatric speciation scenario driven by differences in male anal appendages, either impeding copulation or affecting female preferences. Taken together, the results from this and previous studies in diverse odonate genera suggest that premating barriers have evolved rapidly in ischnuran damselflies and, although reproductive isolation in ischnurans is more commonly the result of several barriers acting together, morphological divergence of second-

ary sexual appendages appears to be a common factor facilitating premating isolation in this group." (Authors)] Address: Sánchez-Guillén, Rosa, Depto de Ecología e Biología Animal, E. U. E. T. Forestal, Universidade de Vigo, Pontevedra, Spain. E-mail: rguillen@uvigo.es

14232. Sánchez-Guillén, R.A.; Muñoz, J.; Hafernik, J.; Tierney, M.; Rodríguez-Tapia, G.; Córdoba-Aguilar, A. (2014): Hybridization rate and climate change: are endangered species at risk? *Journal of Insect Conservation* 18: 295-305. (in English) ["Many species are altering their geographic range due to climate change creating new sympatric populations of otherwise allopatric populations. We investigated whether climate change will affect the distribution and thus the pattern of hybridization between two pairs of closely related damselfly species [*Ischnura damula* and *I. demorsa*, and *I. denticollis* and *I. gemina* (this, an endangered species)]. Thus, we estimated the strength of pre and postmating reproductive barriers between both pairs of species, and we predicted future potential distribution under four different Global Circulation Models and a realistic emissions scenario of climate change by using maximum entropy modelling technique. Our results showed that reproductive isolation (RI) is complete in *I. damula* × *I. demorsa* individuals: F1 (first generation) hybrids are produced but do not reach sexual maturation. However, RI in *I. denticollis* × *I. gemina* hybrids is high but incomplete and unidirectional: only *I. gemina* females produced F1 hybrids which mate with males and females of *I. denticollis* and between them producing BC1 (backcrosses) and F2 (second generation) viable hybrids. Maximum entropy models revealed a northern and westward shift and a general reduction of the potential geographic ranges. Based on the pattern of hybridization, for *I. damula* and *I. demorsa* there is a current threat as well as a rapid displacement and/or extinction of *I. gemina* by *I. denticollis*. However, the current pattern of extinction may not continue due to the contraction in ranges of the four species." 14233. Sanogo, S.; Kabre, J.; Ceccji, P. (2014): Spatial-temporal dynamics of population structure for macro invertebrates families in a continuum dam - effluent - river in irrigated system. *Volta Basin (Burkina Faso)*. *International Journal of Agricultural Policy and Research* 2(5): 203-214. (in English) ["A monthly sampling of benthic macro invertebrates was carried out at the hydro-agricultural dam of Boura in the Volta watershed basin (Burkina) during the period of February through July 2012 in order to describe the structuring of insect succession along with changes occurring in habitats of this irrigated dam farming system. The samples of insects were collected from 6 stations located inside the littoral (Station I), the sublittoral (Station II), the sewage channel or effluent (Stations III, IV, V) and the Mouhoun River (Station VI). The sampling method employed is a conventional method by the European Union

named "Directive Cadre sur l'Eau (DCE)" recommended for the survey of benthic macro invertebrates. The survey reveals a community composed majorly of insects (more than 75%) variously distributed. On one hand at the shoreline and the coastal- adjoining zone in the dam, 23 families of macro invertebrates were identified; mostly belonging to the shoreline except for 10 families identified as endemic to the adjoining zone of the coastline. These two zones of the dam shelter the same malacological fauna consisting of the Unionidae, Lymneidae, Ampullariidae, Planorbidae, Valvatidae and Bulinidae families. The survey reveals otherwise that the differences between the Shannon biological diversity indices for these two zones were more pronounced during the month of July, the rainy period in the basin. On the other hand, concerning the dam-effluent-river continuum, a total of 35 families are sampled: 27 from dam water and stations near the irrigated zones; and 32 from the station of the sewage channel far from the irrigated zone and the river. The identification of individuals belonging to the family of the Baetidae and the Ephemereididae (order of Ephemeroptera) in the river water highlights a subsequent reconstruction of the biodiversity in the river as the presence of both families is an indicator of fertile water. Further analysis on the spatial and temporal distribution involved 17 families out of the 35 sampled not common to all habitats. This lead to the conclusion that changes in natural habitats dictate the clustering patterns of macro invertebrates populations during the year long." (Authors) Taxa - including Gomphidae, Libellulidae and Coenagrionidae - are treated at family level.] Address: Kabre, A., Lab. de Recherche et de Formation en Peche et Faune (LaRFPF/ IDR), Université de Bobo-Dioulasso, BP. 1091 Bobo 01, Burkina Faso. 14234. Sato, M.; Nishijima, S.; Miyashita, T. (2014): Differences in refuge function for prey and tolerance to crayfish among macrophyte species. *Limnology* 15: 27-35. ["The invasive crayfish *Procambarus clarkii* is an omnivore and an ecosystem engineer whose feeding mechanism has reduced the abundance of many native invertebrates and macrophytes. Since macrophytes provide refuges for aquatic insects, macrophyte depletion by crayfish might have indirect negative effects on animal prey in aquatic habitats. We postulated that the prey refuges provided by macrophytes and macrophyte tolerance to crayfish cutting and feeding vary among macrophyte species. We conducted two experiments to (1) investigate differences in macrophyte refuge function for dragonfly larvae against crayfish, and (2) test the tolerance to crayfish cutting and feeding among macrophyte species. *Elodea nuttallii* (submerged plant), *Potamogeton crispus* (submerged plant), and *Carex idzuroei* (emergent plant) had greater refuge effects than *Trapa japonica* (floating-leaved plant), an effect that might result from the larger total cover of *E. nuttallii*, *P. crispus*, and *C. idzuroei*, and the hardness of *C. idzuroei* leaves. Tolerance to crayfish cutting and feeding was greater in *C. idzuroei* than in the other species. As the macro-invertebrate as-

semblages in submerged vegetation are more abundant and species-rich than those in emergent and floating-leaf vegetation, conservation of *E. nuttallii* and *P. crispus* should be prioritized for restoring native aquatic animals in ecosystems invaded by the introduced crayfish. We examined four macrophyte treatments (*E. nuttallii*, *P. crispus*, *T. japonica*, and *C. idzuroei*) and a control (no macrophyte), and measured the predation rates of red swamp crayfish (*Procambarus clarkii*) on a native dragonfly (*Sympetrum baccha matutinum*) in each treatment. Crayfish were collected from Iwata, in Shizuoka Prefecture, while dragonfly larvae were collected from Kashiwa, in Chiba Prefecture. Results: Crayfish predation on dragonfly larvae: In the treatment without crayfish, 97 of 100 dragonfly larvae survived ($n = 2$, ten containers) the entire experiment: the *E. nuttallii*, *P. crispus*, and no macrophyte treatments each had one dead larva. Multiple regression analysis showed that the interaction between macrophyte treatment and day (day represents repeated measures), and day itself were significant for the number of dragonfly larvae, although the number of dragonfly larvae did not differ significantly among macrophyte treatments. This means that the time-related effect of crayfish on the number of dragonfly larvae differed among macrophyte treatments. The rate of decrease in dragonfly larvae was greater in the *T. japonica* and no macrophyte treatments than in the others. The *E. nuttallii* treatment had a greater rate of decrease in dragonflies compared to that of *C. idzuroei*. Logistic regression analysis demonstrated that the interaction between macrophyte species and mass, and mass itself were significant for the survival of dragonfly larvae, whereas macrophyte species was not significant. The significance of the interaction term indicates that the slopes of the relationship between dragonfly larvae survival and macrophyte mass differed among macrophyte species within the given range of macrophyte mass. Post hoc comparisons showed that the slope in the presence of *E. nuttallii*, *P. crispus*, and *C. idzuroei* was significantly greater than that in the presence of *T. japonica*. However, there were no other significant pairwise differences." 14238. Siesa, M.E.; Padoa-Schioppa, E.; Ott, J.; De Bernardi, F.; Ficetola, G.F. (2014): Assessing the consequences of biological invasions on species with complex life cycles: Impact of the alien crayfish *Procambarus clarkii* on Odonata. *Ecological Indicators* 46: 70-77. (in English) ["Highlights: •Invasive species can have complex consequences on species with complex life cycle. •We assessed the impact of *P. clarkii* on the richness of odonate life history stages. •The richness of adult odonates did not reveal any impact of the crayfish. •The richness of larvae and exuviae was negatively affected by the crayfish. •Aquatic life stages are better indicators of the crayfish impact, compared to adults. Abstract: The

temporal dimension is a key parameter when analysing the impact of invasive alien species. Studies on early invasion stages allow a better understanding of how ongoing processes modify native communities, helping to plan effective management actions. *P. clarkii* is an invasive crayfish influencing multiple features of invaded wetlands, but unravelling its impact on organisms with complex life cycles is difficult. We monitored 107 wetlands in Northern Italy, and evaluated the relationships between *P. clarkii* and the richness of three life history stages of odonates: adults, larvae and exuviae. We measured environmental features of each wetland and the natural vegetation in the surrounding landscape. We used an information-theoretic approach to relate species richness of the three life history stages of odonates to: wetland features, features of the surrounding landscape; crayfish presence. We used a spatially explicit technique (Moran Eigenvector Mapping) allowing the integration of spatial autocorrelation into analyses. Wetland and landscape features explained a significant amount of community richness. Wetland hydroperiod, canopy cover and stream velocity were the variables most strongly related to odonate richness. Furthermore, we observed significant relationships between *P. clarkii* and the richness of odonate communities, but the effect of the crayfish on the three odonate stages was different. Species richness measured using both larvae and exuviae was negatively related to the crayfish presence, while negative effects on adults were not evident. Furthermore, negative relationships were observed for Anisoptera but not for Zygoptera. A significant effect of eigenvectors representing spatial configuration suggests an important role of dispersal-related mechanisms in maintaining species richness in invaded wetlands, where fitness is likely lower. Larvae and exuviae may be more helpful for the assessment of the impact of invasive species at early stages of the invasions, while adults may better describe the long term consequences of the invasion at the landscape scale. Considering multiple life-history stages improves our understanding of the impact of biological invasions in freshwaters." (in Italian, with English summary) ["The dragonfly fauna of the moraine amphitheater of Ivrea (Piedmont, NW Italy), an area rich in lentic habitats, including some of the larger lakes of Piedmont, is described. With 48 species, this is one of the most important dragonfly areas of NW Italy. Among the most relevant species in regional scale, the occurrence of *Coenagrion pulchellum*, *Brachytron pratense*, *Onychogomphus uncatus*, *Cordulia aenea*, *Oxygastra curtisii* and *Sympetrum vulgatum* is highlighted. Three species previously recorded for the study area have not been

confirmed during the study (*Symplocma paedisca*, *Erythromma najas*, *Anax ephippiger*)." (Authors)] Address: Sindaco, R., c/o Museo Civico di Storia Naturale, via San Francesco di Sales 88, I-10022 Carmagnola, Italy

14240. Skoglund, L. (2014): Artsamhällen av trollsländor (Odonata) i norrländska tjärnar: identifiering av möjliga indikatorarter för artmångfald. Independent thesis Basic level (degree of Bachelor), Halmstad University, School of Business and Engineering (SET): 18 pp. (in Swedish, with English summary) ["A field study of dragonfly larvae was performed in 20 lakes situated in boreal forest in northern Sweden (in the southeast of Norrbotten county), accompanied by the study of several habitat variables within the locales; fish presence, composition of water vegetation, forestry and the distribution of Sphagnum moss. None of these variables had a proven effect on the species composition of Odonata. This may be due to the fact that species occurring in the north part of the country are generally more tolerant to environmental variables compared to species with a more southern focus of distribution. A shorter growth season implies prolonged life cycles and should in all probability bring about a greater need for habitat tolerance. When a species occurrence is not strictly random the species richness within a region increases/decreases as a result of the presence/absence of specific species which are sensitive to particular variables in their surroundings (deconstructive approach to species richness). Indicator species (indicating general species richness) were distinguished by implementing an analysis of nestedness and the result was compared to a similar study conducted for central Sweden (Sahlén & Ekstubbé, 2001). *E. najas* and *L. quadrimaculata* came forth as suitable indicator species for northern boreal freshwater habitats in this study. In the north they displayed specialist tendencies and were highly selective in their choice of habitats. The same species appears in a very different ecological context when localized to southern Sweden where they are considered trivial species. In addition, temporal follow-ups (repeated stocktakings) of the species composition of small freshwater habitats in this region, and the establishment of accompanying nestedness matrices will allow for the detection of ecological shifts within particular species. These would indicate ongoing restructuring of the Odonate communities and yield information about the impact of climate change." (2014): Photoperiod and variation in life history traits in core and peripheral populations in the damselfly *Lestes sponsa*. *Ecological Entomology* 39: 137-148. (in English) ["(1.) In order to predict evolutionary responses to environmental changes one needs to identify the evolutionary potential in terms of genetic variation of traits and of the traits' plasticity. We studied genetic variance in life his-

tory traits and their reaction norms in response to manipulated photoperiods in central, northern, and northernmost peripheral populations of *Lestes sponsa*. After the central-marginal hypothesis, it is predicted that central populations will express the highest genetic variance. (2.) Northern and northernmost populations showed the highest development and growth rates. All populations expressed shorter development and accelerated growth when raised in a northern compared with a central latitude photoperiod. The slopes of reaction norms differed between regions resulting in a region-by-photoperiod interaction. (3.) There was genetic variation in development time; however, it did not differ across regions. There was no genetic variation in growth rate or in the plasticity of development time and growth rate to photoperiod. (4.) Results did not support the central-marginal hypothesis. However, evidence was found that the development time has the potential to evolve at similar rates across study regions. In contrast, the growth rate seems to be genetically constrained for further evolution, probably because of a strong past directional selection on this trait. The presence of low genetic variation in the slope of the reaction norms could be a result of stabilising selection imposed by seasonality." (in English) ["Resilin is an elastomeric protein found in insect cuticles and is remarkable for its high strain, low stiffness, and high resilience. Since the first resilin sequence was identified in *Drosophila melanogaster* (fruit fly), researchers have utilized molecular cloning techniques to construct resilin-based proteins for a number of different applications. In addition to exhibiting the superior mechanical properties of resilin, resilin-based proteins are autofluorescent, display self-assembly properties, and undergo phase transitions in response to temperature. These properties have potential application in designing biosensors or environmentally responsive materials for use in tissue engineering or drug delivery. Furthermore, the capability of resilin-based biomaterials has been expanded by designing proteins that include both resilin-based sequences and bioactive domains such as cell-adhesion or matrix metalloproteinase sequences. These new materials maintain the superior mechanical and physical properties of resilin and also have the added benefit of controlling cell response. Because the mechanical and biological properties can be tuned through protein engineering, a wide range of properties can be achieved for tissue engineering applications including muscles, vocal folds, cardiovascular tissues, and cartilage." 14243. Sun, J.; Ling, M.; Pan, C.; Chen, D.; Tong, J.; Li, X. (2014): Biomimetic structure design of dragonfly wing

vention using topology optimization method. *Journal of Mechanics in Medicine and Biology* 14, 1450078, DOI: 10.1142/S021951941450078X: 17 pp. (in English) ["Scientists have carried out research for various biomimetic applications based on the dragonfly wings because of the superb flying skills and lightsome posture. The wings of dragonflies are mainly composed of veins and membranes, which give rise to the special characteristics of their wings that make dragonflies being supremely versatile, maneuverable fliers. Mimicking the dragonfly wing motion is of great technological interest from application's point of view. However, the major challenge is the biomimetic fabrication to replicate the wing motion due to the very complex nature of the wing venation of dragonfly wings. In this regard, the topology optimization method (TOM) is useful to simplify object's structure while retaining its mechanical properties. In this paper, TOM is employed to simplify and optimize the venation structure of *Pantala flavescens* wing that is captured by a 3D scanner and numerical reconfiguration. Combined with the material parameters obtained from nanoindentation testing, the quantitative models are established based on a finite element (FE) analysis and discussed in static range. The quantitative models are then compared with the square frame, staggered grid frame and hexagonal frame to examine the potentials of the biomimetic structure design for the fabrication of greenhouse roof." 14245. Sviderskii, V.L.; Plotnikova, S.I.; Gorelkin, V.S.; Severina, I.Yu.; Isavnina, I.L. (2014): Functional role of dragonfly legs before and after wing formation: Rearrangement of coordinatory relationships. *Neuroscience and Behavioral Physiology* 44(7): 804-809. (in English)

["We report here our studies of the characteristics of the structural-functional organization of the leg apparatus of the dragonfly *Aeshna grandis*, in larvae of the final instar, whose legs have a locomotor function, and in adult winged individuals (imagoes), whose legs have lost their locomotor function and are used mainly as traps to catch prey in the air. Neither the shape nor the proportions of individual leg segments in imagoes were significantly different from those in larvae, and all changes in the functional role of the legs in imagoes occur as a result of changes in the mechanisms controlling the functioning of the leg muscles and the corresponding rearrangements in coordinatory relationships. These rearrangements, as evidenced by the data reported here, affect the mechanisms generating motor commands, the appearance of a tight correlation in the operation of the wing muscles and the leg apparatus, and various others. These mechanisms are discussed." (Authors) Address: Sviderskii, V.L., Sechenov Institute of Evolutionary Physiology and Biochemistry, Russian Academy of Sciences, 44 M. 14246. Tajima, Y.; Watanabe, M. (2014): Counter-adaptation in response to sperm removal by stimulating the sensory system in female *Ischnura asiatica* (Odonata: Coenagrionidae). *Odonatologica* 43(1/2): 115-124. (in English) ["The male *Ischnura asiatica* (Brauer, 1865) has a pair of horns on its penis head. Because each horn is shorter than the spermathecal duct, the spermatheca is inaccessible to the male. Thus, males can not directly displace spermathecal sperm using the horns. Nevertheless during copulation displacement of sperm from the spermatheca does occur. By stimulating vaginal sensilla that communicate the presence of an egg to the muscles surrounding the sperm storage organs, sperm ejection can be induced as fertilization is anticipated by the female. Males with a large penis head might be better adapted to stimulate the sensilla and displace more sperm than those with a small penis head. From the viewpoint of females, on the other hand, there are costs if complete sperm displacement occurs. Decreasing the number of sensilla might make it difficult for the male's stimulation to displace spermathecal sperm, especially where a population includes males with a large penis head. To test this hypothesis, the width of the penis head and the number of sensilla were measured in several local populations, with different body sizes, distributed in mainland Japan. The number of sensilla decreased with the width of the penis head. Therefore, a low number of sensilla in the females might be a counter-adaptation against the male sensory stimulation." 14247. Takahashi, Y.; Kagawa, K.; Svensson, E.I.; Kawata, M. (2014): Evolution of increased phenotypic diversity enhances population performance by reducing sexual harassment in damselflies. *Nature communications* | 5: 4468 | DOI: 10.1038/ncomms5468: 7 pp. (in English)

["The effect of evolutionary changes in traits and phenotypic/genetic diversity on ecological dynamics has received much theoretical attention; however, the mechanisms and ecological consequences are usually unknown. Female-limited colour polymorphism in damselflies is a counter-adaptation to male mating harassment, and thus, is expected to alter population dynamics through relaxing sexual conflict. Here we show the side effect of the evolution of female morph diversity on population performance (for example, population productivity and sustainability) in damselflies. Our theoretical model incorporating key features of the sexual interaction predicts that the evolution of increased phenotypic diversity will reduce overall fitness costs to females from sexual conflict, which in turn will increase productivity, density and stability of a population. Field data and mesocosm experiments support these model predictions. Our study suggests that increased phenotypic diversity can enhance population performance that can potentially reduce extinction rates and thereby influence macroevolutionary processes." 14252. Therry, L.; Gyulavári, H.A.; Schillewaert, S.; Bonte, D.; Stoks, R. (2014): Integrating large-scale geographic patterns in flight morphology, flight characteristics and sexual selection in a range-expanding damselfly. *Ecography* 37: 1012-1021. (in English) ["While geographic trait variation along environmental clines is widespread, associated patterns in sexual selection remain largely unexplored. Geographic patterns in sexual selection may be expected if 1) phenotypes vary geographically and sexual selection is dependent on the local phenotypes in the population, and if 2) sexual selection is influenced by geographically structured environmental conditions. We quantified geographic variation in flight-related traits and flight performance in mated and unmated males and tested for geographic variation in sexual selection on these traits in the poleward range-expanding damselfly *Coenagrion scitulum* across a set of eleven core and edge populations ordered along thermal gradients in the larval and in the adult stage. We found little support for trait differentiation between core and edge populations, instead we found considerable geographic trait variation along the larval and adult thermal gradients. As expected under time constraints, body mass decreased with shorter larval growth seasons. Lower temperatures during the adult flight period were associated with a higher body mass, a higher flight speed and a higher fat content; these traits likely evolved to buffer flight ability at subop-

timal temperatures and to optimize starvation resistance. Across the large geographic scale, we found a consistent higher flight duration in mated males. Instead, sexual selection for higher fat content was stronger in populations with lower adult flight temperatures and sexual selection for lower body mass acted only in edge populations. Our results indicate sexual selection on flight performance to be consistent over a large geographic scale and this despite the clear geographic patterns in sexual selection on the underlying morphological traits. Our results highlight that to fully understand the fitness implications of geographically changing trait patterns, researchers should consider the entire phenotype–performance–fitness axis and incorporate effects of geographically structured life-stage specific environmental conditions on this axis." 14255. Touchon, J.C.; Wojdak, J.M. (2014): Plastic hatching timing by Red-eyed treefrog Embryos Interacts with larval predator identity and sublethal predation to affect prey morphology but not performance. *PLoS ONE* 9(6): e100623. doi:10.1371/journal.pone.0100623: 9 pp. (in English) ["Many animals respond to predation risk by altering their morphology, behavior, or life-history. We know a great deal about the cues prey respond to and the changes to prey that can be induced by predation risk, but less is known about how plastic responses to predators may be affected by separate plastic responses occurring earlier in life, particularly during the embryonic period. Embryos of a broad array of taxa can respond to egg- or larval-stage risks by altering hatching timing, which may alter the way organisms respond to future predators. Using the red-eyed treefrog (*Agalychnis callidryas*), a model for understanding the effects of plasticity across life-stages, we assessed how the combined effects of induced variation in the timing of embryo hatching and variation in the larval predator community impacted tadpole morphology, pigmentation and swimming performance. We found that *A. callidryas* tadpoles developed deeper tail muscles and fins and darker pigmentation in response to fish predators, either when alone or in diverse community with other predators. Tadpoles altered morphology much less so to dragonfly naiads (*Pantala flavescens*) or water bugs. Interestingly, morphological responses to predators were also affected by induced differences in hatching age, with early and late-hatched tadpoles exhibiting different allometric relationships between tail height and body length in different predator environments. Beyond induced morphological changes, fish predators often damaged tadpoles' tails without killing them (i.e., sublethal predation), but these tadpoles swam equally quickly to those with fully intact tails. This was due to the fact that tadpoles with more damaged tails increased tail beats to achieve equal swimming speed. This study demonstrates that plastic phenotypic responses to predation risk can be influenced by a complex combination of responses to both the embryo and larval environments, but also that prey performance can be highly resilient to sublethal predation." 14256. Umezu, S.; Tanabe, N.; Hashimoto, H. (2014): Fabrication of comb shape of leading edge wing of dragonfly. *Key Engineering Materials* 625: 182-186. (in English) ["Research on Micro air vehicle (MAV) has been carried out by many researchers to gather information in environmental monitoring, security and so on. When the earthquake, fire, smoke take place, it is difficult for human beings to investigate the detail because of dangerous condition. However, MAV has possibility to investigate the detail because MAV can fly freely around. Recently, dragonfly is highly focused by many researchers because dragonfly has high flight performances those are high efficiency flight, unintended acceleration, rapid turn and hovering. In general, these characteristics have root that wing is corrugation shape. We focus on microstructures on wing and its aerodynamic characteristics because there are many unique microstructures. We focused on micro spikes on dragonfly wing. Over three thousands of spikes exist on two sides of wing. The length and shape of spikes are 10 to 100 micron meters and oblique circular cone. It is important to clear the aerodynamic effect of the oblique circular cone. Artificial wing was fabricated by following processes. We fabricated micro spikes utilizing electro polishing. Fabricated micro spikes were set on plate utilizing micro spot bonding. We investigated the flow around the artificial wing and found that the flow around wing was controlled by micro spikes on wing. In this paper, we focused on comb shape of leading edge of wing. Comb shape is fabricated utilizing micro-EDM. We investigate flow characteristics of comb shape." 14257. Van, K.D.; Janssens, L.; Debecker, S.; Stoks, R. (2014): Warming increases chlorpyrifos effects on predator but not anti-predator behaviours. *Aquatic Toxicology* 152: 215-221. (in English) ["Highlights: •Pesticide effects on predator and antipredator traits may depend on temperature. •We tested for temperature-sensitivity to chlorpyrifos in damselfly larvae. •Chlorpyrifos reduced key predator behaviours stronger at the higher temperature. •Chlorpyrifos reduced escape speed to the same extent at the high temperature. •Temperature dependence of the pesticide effects was similar at different latitudes. Abstract: Recent insights indicate that negative effects of pesticides on aquatic biota occur at concentrations that current legislation considers environmentally protective. We here address two, potentially interacting, mechanisms that may contribute to the underestimation of the impact of sublethal pesticide effects in single species tests at room temperature: the impairment of predator and antipredator behaviours and the stronger impact of organophosphate pesticides at higher temperatures. To address these issues we assessed the effects of chlorpyrifos on the predator and antipredator behaviours of larvae of the damselfly *Ischnura elegans*, important in-

termediate predators in aquatic food webs, in a common-garden warming experiment with replicated low- and high-latitude populations along the latitudinal gradient of this species in Europe. Chlorpyrifos reduced the levels of predator behavioural endpoints, and this reduction was stronger at the higher temperature for head orientations and feeding strikes. Chlorpyrifos also impaired two key antipredator behavioural endpoints, activity reductions in response to predator cues were smaller in the presence of chlorpyrifos, and chlorpyrifos caused a lower escape swimming speed; these effects were independent of temperature. This suggests chlorpyrifos may impact food web interactions by changing predator-prey interactions both with higher (predators) and lower trophic levels (food). Given that only the interaction with the lower trophic level was more impaired at higher temperatures, the overall pesticide-induced changes in food web dynamics may be strongly temperature-dependent. These findings were consistent in damselflies from low- and high-latitude populations, illustrating that thermal adaptation will not mitigate the increased toxicity of pesticides at higher temperatures. Our study not only underscores the relevance of including temperature and prey-predator interactions in ecological risk assessment but also their potential interplay and thereby highlights the complexity of contaminant effects on predator-prey interactions being differentially temperature-dependent pending on the trophic level." 14258. Van Buskirk, J.; Krügel, A.; Kunz, J.; Miss, F.; Stamm, A. (2014): The rate of degradation of chemical cues indicating predation risk: An experiment and review. *Ethology* 120(9): 942-949. (in English) ["Many prey taxa use kairomones or alarm pheromones to assess the risk of predation in aquatic environments, and the rate at which these cues attenuate determines how precisely they indicate the local density of predators. We estimated the rate of degradation of chemical cues generated by *Aeshna* dragonfly larvae feeding on *Rana temporaria* tadpoles. The half-life of the cue was 35 h and was not influenced by whether it was aged in pond water or tap water or whether other tadpoles were present in the container in which cue-aging occurred. A review of other published estimates of predator cue half-life revealed values of 0.2–126 h, and variation among studies was unrelated to the type of aging water, the venue in which water was aged or prey behaviour observed (laboratory, field), or the type of behaviour that was recorded. We conclude that factors affecting the persistence of predator cues remain uncertain in spite of their importance for understanding the evolution of induced defenses." 14259. Van Praet, N.; De Bruyn, L.; De Jonge, M.; Vanhaecke, L.; Stoks, R.; Bervoets, L. (2014): Can dam-

selfly larvae (*Ischnura elegans*) be used as bioindicators of sublethal effects of environmental contamination?. *Aquatic Toxicology* 154: 270-277. (in English) ["The present study measured various pesticides and trace metals, together with sublethal effect biomarkers (lipid, protein and glycogen levels, acetylcholinesterase (AChE) and glutathione-S-transferase (GST) activities) in damselfly larvae (*Ischnura elegans*) at sixteen sampling sites in Flanders (Belgium). Four pesticides (chloridazon, dichlorvos, terbutylazine, metolachlor), some of them hardly measurable in surface water, and all trace metals were above the limit of quantification in damselfly tissue. A principal component analysis (PCA) on the accumulated pollutant concentrations returned five pollutant axes explaining 85.8% of the total variation. Based on these PCA-axes a hierarchical cluster analysis revealed that the 16 sampled ponds could be classified in 7 groups. Increasing dichlorvos levels in the animals resulted in a lower body mass. Body mass was negatively correlated with GST and AChE activities, lipid and glycogen levels. The present findings provide evidence of toxicity-induced sublethal stress of dichlorvos accumulation in natural populations of *I. elegans*." 14264. Weerakkodi, W.G.I.S.; Amarasinghe, L.D. (2014): Rice field and marshland inhabiting mosquitoes and some physico-chemical and biological parameters affecting their abundance. *Proceedings of the 33th annual sessions of the institute of biology*, 27th September 2013. Abstract number 1-11: (in English) [Verbatim: Mosquito larval survey was carried out in rice fields and marshlands in Kelaniya area, Gampaha District, Sri Lanka from March to July 2012 to determine the variation of mosquito larval density and diversity. Further, the study investigated the physico-chemical and biological parameters associated with mosquito larval density in the two habitats. Larval sampling and recording of physico-chemical and biological parameters was carried out biweekly within the study period in five sampling sites per habitat within an extent of 20 km² in Kelaniya area. Larval samples

were identified up to the species level using keys in the laboratory using 4th instars and adult mosquitoes. Morphological identification of 1071 mosquito larvae collected from rice fields and 576 mosquito larvae collected from marshlands (150 scoops per habitat) revealed 08 species of mosquitoes of 04 genera in rice fields and 08 species of 03 genera from marshlands. Both habitats were dominated by Genus *Culex* (97.5% in rice fields and 95.4% in marshlands). *Culex tritaeniorhynchus* and *Culex gelidus* were represented the majority of samples. Mosquito larval density in rice field and marshland habitats in Kelaniya area was not significantly different ($P > 0.05$). Rice fields are the most diverse habitats from two selected habitat types in Kelaniya area (Shannon wiener diversity index/ $H^1 = 1.35$ in rice fields and $H^1 = 1.25$ in marshlands). However, they were mainly associated with high Total Dissolved Solid (>10.00 mg/L), 6-8 pH level, low Dissolved Oxygen (5.0-6.0 mg/L), < 5.0 mg/L nitrate and less than 1.0mg/L phosphate levels. They can tolerate a range of BOD levels in water. Further their habitats were positively associated with Chironomid larvae, phytoplanktons of Family Zygnemataceae, Clamydomonadeceae and Family Oscillatoriaceae and zooplanktons of Family Acanthocystis and Daphniidae, whereas negatively associated with larvae of Family Libellulidae of Order Odonata. Fourteen families of phytoplankton and 16 families of zooplankton were recorded associating mosquito larvae from rice fields and marshlands.] Address: Amarasinghe, L.D.D, Department of Zoology, University of Kelaniya, Sri Lanka. 14265. Weihrauch, F. (2014): Editorial. *Odonatologica* 43(1/2). *Odonatologica* 43(1/2): 1. (in English) [Verbatim: Nothing in life is as certain as change. However *Odonatologica* has seemed to defy this rule, as it has persisted practically unchanged for an extraordinary 42 years under the editorship of Professor Bastiaan Kiauta. This remarkable feat of endurance must be ranked a signal success in the history of our science. I am not entirely sure why Bastiaan chose me to become his successor. I have to admit that I have been quite reluctant for almost two years to accede to his proposal because I was and still am well aware that the footprints he has left, highly visible in the recent past, are impossible to emulate no matter how hard I try. On the other hand, I have served with enthusiasm as editor of the German journal *Libellula* for almost a decade. As a passionate producer of dragonfly journals, this was an offer I simply could not refuse and I suppose Bastiaan knew that. However, in undertaking this task, I look back at Bastiaan's life's work with immense respect and admiration, and with some trepidation promise to do my best to repay his confidence in me. Too many names have been involved in the production of *Odonatologica* during the past 42 years to list them all here – they include associate editors and members of the editorial board, S.I.O. officers, peer reviewers, authors, and many, many more. An appraisal of most names can be found in Bastiaan's Editorial in *Odonatologica* 42 (4) and, because they established the foundation

on which I can build today, my sincere thanks go out to all of them. I would particularly like to single out two individuals from the S.I.O. board of trustees for special gratitude. They are Kiyoshi Inoue, President of the S.I.O, and Marianne Kiauta, the guardian angel of *Odonatologica*, who both in my eyes not only carry the banner of *Odonatologica*'s past success, but who have also welcomed me into my new role with a warmth and friendliness that was both irresistible and touching. I look forward to a fruitful collaboration with all members of the odonatological society in the near and more distant future, and hope to receive many manuscripts, so that *Odonatologica* may remain as it always has been – a seminal and attractive journal for everyone interested in dragonfly research.]" Address: Weihrauch, F., Jägerstr. 21A, D-85283 Wolnzach, Germany. E-mail: Florian.Weihrauch@t-online.de

14266. Westermann, E. (2014): Erfolgreiche Entwicklung der Großen Heidelibelle (*Sympetrum striolatum*) im Oberen Hotzenwald (Hochschwarzwald) auf 900 m Meereshöhe. *Naturschutz am südlichen Oberrhein* 7: 226-227. (in German, with English summary) [Germany. "In 2012 at least 15 Common Darters emerged successfully at the Hierholzer Weiher (community of Dachsberg, district of Waldshut) at 900 m a.s.l. This species was probably not present at this location from 2003 to 2005 and in 2013. So far reproduction has not been recorded above 800 m in Baden-Württemberg." 14267. Westermann, K.; Westermann, E. (2014): Die Libellenfauna des Klosterweihers im südlichen Hochschwarzwald. *Naturschutz am südlichen Oberrhein* 7: 228-234. (in German, with English summary) [Baden-Württemberg, Germany. "From 2000 to 2003 and in particular from 2011 to 2013 the dragonflies around the Klosterweiher (community of Dachsberg, district of Waldshut) were recorded over 34 days. In 1953 this pond, which is located at 944 m above sea level, was formed over moorland and currently has a size of almost three hectares. Over the last decades a wide siltation zone with reed and moor areas has developed which has been protected since 2005 by the „Friedrich-August-Grube“ nature reserve. The part open to the public is intensively used for bathing. On an easily accessible part, which is also very attractive for dragonflies, exuviae were collected and imagoes were recorded. From a total of 20 species recorded, at least 16, possibly 17, developed successfully almost every year. Outstanding species were the moor dragonflies *Coenagrion hastulatum*, *Aeshna juncea* and *Aeshna subarctica*. However, from the latter, only one exuvia has been found so far. The Klosterweiher was shown to be highest known emergence site in the Black Forest for *Lestes viridis* and *Platycnemis pennipes*. The habitats of the dragonflies in the siltation zone can only be secured in the medium term by regular management measurements." (Authors)] Address: Westermann, K., Buchenweg 2, 79365 Rheinhausen, Germany. E-mail: fosor@t-online.de

14268. Westermann, K.; Westermann, E. (2014): Zur Emergenz großer Populationen des Spitzenflecks (*Libellula fulva*) und des Frühen Schilfjägers (*Brachytron pratense*) im kühlen Frühjahr 2005 an einem kleinen Quellgewässer der Rheinniederung. *Naturschutz am südlichen Oberrhein* 7: 210-218. (in German, with English summary) [Baden-Württemberg, Germany. "During the cool and rainy spring of 2005 I investigated daily the emergence of huge populations of *L. fulva* and *B. pratense* in a small, largely reed-covered spring water body in the Rhine plain of the northern part of the district of Emmendingen. the emergence period lasted for approximately five weeks with a peak period of 12 and 14 days, respectively. A synchronization of the metamorphosis was not detectable in either species. Seven days after the first emergence of a *Brachytron* male the first territorial flight was observed. the corresponding time period in *L. fulva* was 20 days and therefore three times longer. the recordable losses were small in both species although the weather was unfavourable. At the same water body *Cordulia aenea* and *Somatochlora flavomaculata* also emerged in significant numbers. Among the four species significant differences in the selection of places for emergence were noted. *L. fulva* was by far the most frequent species with a minimum of 485 freshly emerged adults. For this species further data regarding selected substrate for emergence, weather impact, mechanisms for prevention of losses and inhomogeneity of the time course of emergence between the sexes were recorded." (Authors)] Address: Westermann, K., Buchenweg 2, 79365 Rheinhausen, Germany. E-mail: fosor@t-online.de

14269. Westermann, K.; Westermann, E. (2014): Eine autochthone Population der Speer-Azurjungfer (*Coenagrion hastulatum*) in Moorgewässern des Oberen Hotzenwalds – Erste Nachweise für den südlichen Hochschwarzwald. *Naturschutz am südlichen Oberrhein* 7: 219-225. (in German, with English summary) [Baden-Württemberg, Germany. "In 2012 and 2013 local populations of *C. hastulatum* were recorded for the first time in the upper Hotzenwald (district of Waldshut). Currently, autochthonous local populations exist in the siltation zone of the Klosterweiher (community of Dachsberg), and in the moor ponds of the Föhrenmoos (community of Ibach). Due to progressive siltation a population decrease is expected in both water bodies. Possible protection measures for the permanent conservation of a self-sustaining regional population are discussed." (Authors)] Address: Westermann, K., Buchenweg 2, 79365 Rheinhausen, Germany. 14270. Wlasichuk, C. (2014): The impacts of cattle grazing on stream ecosystems in Grasslands National Park of Canada, Saskatchewan. M.Sc. thesis, Department of Entomology, University of Manitoba, Winnipeg: XIII + 177 pp. (in English) ["Cattle are responsible for the deterioration of aquatic and riparian ecosystems throughout the North American prairies. Marked preference for riparian areas has resulted in vegetation loss, stream bank de-

stabilization, changes in sediment particle size, and increased nutrient loads in the streams. A grazing experiment in Grasslands National Park of Canada manipulated the density of cattle to represent a range of grazing intensities (from no grazing to very heavy grazing, 70% forage utilization). This experiment provided the opportunity to study how streams in the semi-arid mixed-grass prairie environment respond to a range of grazing pressure. Nine experimental pastures located on previously ungrazed land within the park boundary and four located within the adjacent community pastures were created, each subjected to a specified grazing treatment. Sampling occurred in the autumn from 2007 to 2009 and included the measurement of 33 physical, chemical, and biological habitat metrics and the characterization of the aquatic invertebrate community. Linear regressions were performed to determine if the habitat variables had a significant relationship to grazing intensity ($P < 0.05$). Of the habitat variables, two sediment particle size categories were significantly related to grazing intensity: per cent of fine gravel (4-8 mm diameter) ($P = 0.003$) and per cent of medium gravel (8-16 mm diameter) ($P = 0.007$). The only other habitat variable with a significant linear relationship to grazing intensity was the concentration of suspended carbon in the stream water ($P = 0.050$). Three invertebrate community metrics were focused on for their expected response to changes associated with cattle impacts: iii per cent Chironomidae (%Chiron), per cent Ephemeroptera, Odonata, and Trichoptera (%EOT), and taxa richness. There was a significant non-linear relationship between %Chiron ($P = 0.005$) and grazing intensity, no linear or non-linear relationship between %EOT and grazing intensity, and a non-linear trend between richness and grazing intensity ($P = 0.083$). A Reference Condition Approach was used to test for the effects of grazing on the invertebrate community. Multiple regression was used to create a model predicting the invertebrate community from habitat metrics. Of the three community metrics, only richness resulted in a model with acceptable predictive ability. The predicted richness values for each test site were calculated and their residuals were determined and compared to the distribution of residuals observed in the reference sites. Using this technique, I determined that 73.3% of the sites subjected to grazing deviated significantly for the reference condition and were therefore deemed to be impacted. There was no significant relationship between the test site residuals and grazing intensity. The macroinvertebrate community in this semi-arid environment is already under a lot of stress, the addition of cattle to the environment, even at low intensities, pushed the community beyond the reference condition." (Author)] Address: Wlasichuk, Cynthia. University of Manitoba, Canada

14271. Wojdak, J.M.; Touchon, J. C.; Hite, J.L.; Meyer, B.; Vonesh, J.R. (2014): Consequences of induced hatching plasticity depend on predator community. *Oecologia* 175(4): 1267-1276. (in English) ["Many prey species face trade-offs in the timing of life history switch points like

hatching and metamorphosis. Costs associated with transitioning early depend on the biotic and abiotic conditions found in the subsequent life stage. The red-eyed treefrog, *Agalychnis callidryas*, faces risks from predators in multiple, successive life stages, and can hatch early in response to mortality threats at the egg stage. Here we tested how the consequences of life history plasticity, specifically early hatching in response to terrestrial egg predators, depend on the assemblage of aquatic larval predators. We predicted that diverse predator assemblages would impose lower total predation pressure than the most effective single predator species and might thereby reduce the costs of hatching early. We then conducted a mesocosm experiment where we crossed hatchling phenotype (early vs. normal hatching) with five larval-predator environments (no predators, either waterbugs, dragonflies (*Pantala flavescens*), or mosquitofish singly, or all three predator species together). The consequences of hatching early varied across predator treatments, and tended to disappear through time in some predation treatments, notably the waterbug and diverse predator assemblages. We demonstrate that the fitness costs of life history plasticity in an early life stage depend critically on the predator community composition in the next stage." 14272. Xu, M.; Cerreta, A.L.; Schultz, T.D.; Fincke, O.M. (2014): Selective use of multiple cues by males reflects a decision rule for sex discrimination in a sexually mimetic damselfly. *Animal Behaviour* 92: 9-18. (in English) ["Discriminating between the sexes when one sex resembles the members of the other sex may be challenging. When sexual mimicry imposes costs on signal receivers, receivers can minimize confusion by using nonmimetic cues that differ between the models and the mimics. We tested this hypothesis in a female-specific polymorphic damselfly *Enallagma hageni*, whose blue coloration of andromorphic females resembles that of males, whereas the heteromorphic females have a distinctive green colour. Both female morphs share an abdominal pattern that differs from the males'. We predicted that males selectively use both colour (the mimetic cue) and pattern (the nonmimetic cue) in sex recognition: they use the nonmimetic cue only when the encountered individual has the mimetic colour. We modified the abdominal pattern of males, andromorphs and heteromorphs to resemble that of the opposite sex, and recorded males' reactions to pattern-altered and control individuals both in an arena and in the field. Our results supported our hypothesis. We then derived and tested potential male decision rules based on the two visual cues for sex recognition. We presented focal males with unnatural, orange females possessing either a male or female abdominal pattern, and recorded the reactions of mate-searching males to individuals with a novel pink-painted phenotype. Males reacted sexually to orange- and pink-painted individuals regardless of the abdominal pattern. Collectively, our re-

sults support a male discrimination rule of 'if not blue, then female', providing insights into the origin of phenotypic novelty in colour-polymorphic species." 14276. Yoshimura, M.; Akama, A. (2014): Radioactive contamination of aquatic insects in a stream impacted by the Fukushima nuclear power plant accident. *Hydrobiologia* 722: 19-30. (in English) ["The Fukushima Daiichi Nuclear Power Plant accident emitted radioactive substances into the environment, contaminating a diverse range of organisms. Stream algae, litter, sand substrate, aquatic insects and fishes are among the organisms that have been impacted. Radioactive Cs contaminations in the litter and sand substrate were elevated where the atmospheric dose rate in the air was high. Radioactive Cs contaminations in algae and aquatic insects varied irregularly; nevertheless, radioactive Cs contaminations in aquatic insects in pools were consistently higher than those in stream riffles. Contamination by the radioactive Cs differed by species, location and stream velocity. This study was undertaken in a limited number of samples and sites, with more extensive studies planned to fully determine the impact of radionuclides on aquatic ecosystems. ... Small sample sizes for the Perlidae, Heptageniidae, Stenopsychidae and Hydropsychidae in the pool and for the Chloroperlidae, Ephemeridae and Gomphidae (*Davidius nanus*) in the riffle made statistical analysis difficult, but there was trend toward lower radioactive Cs values in the riffle compared to those in the pool. The radioactive Cs values of the sand substrate in the riffle were 30 ± 4.12 Bq/kg for ^{134}Cs and 58 ± 12.9 Bq/kg for ^{137}Cs . The radioactive Cs values of the sand substrate in the pool were 14 ± 2.98 Bq/kg for ^{134}Cs and 25 ± 3.08 Bq/kg for ^{137}Cs ." 14280. May, M.L. (1997): The status of some species of *Enallagma* (Odonata: Zygoptera: Coenagrionidae). Ent. news. 108(2): 77-91. [I have investigated the identity and generic placement of five little known species of coenagrionid damselflies usually assigned to *Enallagma*. Of these, *E. camerunense* is shown not to belong to *Enallagma* but probably to be an aberrant *Pseudagrion*. *E. kauderni*, commonly regarded as a subspecies of *E. nigridorsum*, appears to be as well-differentiated from the latter as either is from *E. vansomereni*. so I consider *E. kauderni* to be a full species. Examination of the type of *E. melanotum* demonstrated it to be identical with *Agrion* (now *Cercion*) *sexlineatum*. *E. pseudelongatum* has been incorrectly placed as a synonym of *E. elongatum* in recent catalogs, probably owing to misinterpretation of Eraser's (1947) comparison of these distinct species. Finally, *E. strouhali* is apparently identical with the earlier described *E. risi*; I also discuss the possible relations of these taxa to *E. cyathigerum* and *E. boreale*.] (Author)]

14288. Wada, S. (2000): Observation on a Y-shaped triple connection of *Lestes temporalis* Selys. Tombo 42: 61-62. (in Japanese, with English summary) ["A Y-shaped triple connection, two males simultaneously in tandem with a female of *L. temporalis* was observed from its formation to separation at Sano-cho, Fukui-shi, Fukui Pref. on September 25, 1999 and some pictures of this unusual connection including pre-formation were taken during the observation. At that time, more than 30 tandems of the species were observed and there was no single female excepting one caught in a web, so a single male had no chance but to snatch a female in tandem. Moreover, the tandem interrupted by the single male was being caught in a tree and could not shake off the interrupting male easily. And the superior appendages of a male of the species is relatively longer than those of other species, and the period of the species in tandem is longer than other species, which seem to make it easier for the species to form this kind of unusual connection." (Author)] Address: Wada, S., 3-8-18 Nishikida, Fukui 918-8004, Japan

14289. Wada, S. (2000): New records of *Davidius moiwanus tarui* Asahina et Inoue from Fukui Prefecture. Tombo 42: 69-70. (in Japanese, with English summary) ["Some adults and larvae and exuviae of *Davidius moiwanus tarui* were collected at Shinjo, Mihama-cho, Fukui Pref. mainly in the spring of 1999. These are the first records of the species from Fukui Pref., Japan. Average lengths of the collected males' abdomen and hind wing are 31.68mm and 23.50mm respectively, and the females' are 27.86mm and 24.86mm respectively. These individuals seem to come close to those of the Hira Mountains rather than the Noto Peninsula judging from the size of them." (Author)] Address: Wada, S., 3-8-18 Nishikida, Fukui 918-8004, Japan

14290. Wada, S. (2000): A record of a teneral female of *Anax guttatus* in Fukui Prefecture. Tombo 42: 71. (in Japanese, with English summary) ["A female of *Anax guttatus* just after emergence was collected at Hananao-naka 2-chome, Fukui-shi, Fukui Pref., central Japan on October 22, 1999. In the last year 1998, exceedingly many adults

of the species were observed all over Fukui Pref., but in this year no adults observed except for the teneral female in the prefecture." (Author)] Address: Wada, S., 3-8-18 Nishikida, Fukui 918-8004, Japan

14291. Yokota, H.; Watanabe, Y. (2000): Larval breeding record of *Stylurus annulatus* (Djakonov). Tombo 42: 49-53. (in Japanese, with English summary) ["In September 1996, a female *S. annulatus* was caught at the shore of Lake Biwa, Shiga Prefecture. The eggs had brandy glass shaped process which adhere to settle, and the first instar larvae had two rows of spine like structures which disappear in the second instar. These features are common to the other two Japanese *Stylurus* species. The eggs hatched in two weeks and the larvae were bred in the laboratory. Rapid growing group hibernated in the fifth instar, and four males and four females emerged in July and August 1997. Slow growing group larvae hibernated in the third or fourth instar, and again in the final instar in the next winter. Four males and two females emerged in May and June, 1998 from the latter group." 2004

14296. Futahashi, R.; Futahashi, H. (2004): Record of the type 0 triple-connection of *Anax nigrofasciatus nigrofasciatus* Oguma, 1915. *Aeschna* 41: 37-38. (in Japanese, with English summary) ["We observed the type 0 triple-connection of *Anax nigrofasciatus nigrofasciatus*. At first, a second male of *Anax nigrofasciatus nigrofasciatus* connected with a female copulating with the first male. They were flying a few minutes and fell on the ground, making a mass resulting in type 0 triple-connection. Then, the second male separated, leaving the female copulated with the first male only by his copulatory organs." (Authors)] Address: Futahashi, R., National Institute of Advanced Industrial Science and Technology (AIST), Central 6, Tsukuba, Ibaraki 305-8566 Japan. E-mail: ryo-futahashi@aist.go.jp

14297. Futahashi R., Hayashi F. (2004): Distribution patterns of two damselfly species, *Mnais costalis* and *M. strigata*, in the Bôshô Peninsula, Chiba Prefecture. *Tombo* 47: 41-46. (in Japanese, with English summary) ["A total of 106 *Mnais* damselflies collected from the Bôshô Peninsula, Chiba Prefecture, central Japan, were classified into *M. strigata* Selys, 1853 (48 males, 9 females), *M. costalis* Selys, 1869 (40 males, 8 females), and their hybrid Fr1 (1 female) based on DNA sequences of a nuclear ribosomal internal transcribed spacer I (ITS I). The peculiar form *edai Asahina*, 1976 known from this peninsula was identified as one wing-colour form of *M. strigata*. The two species were distributed parapatrically with a narrow contact zone: i. e., *M. strigata* was restricted to the southern mountainous area of the Bôshô Peninsula, while *M. costalis* was distributed in the northern area of the Kanto plain. The two species were quite similar in their external morphology, excluding some different relationships between head width and forewing length and between pterostigma length and width. (Authors)] Address: Futahashi, R., National Institute of Advanced Industrial Science and Technology (AIST), Central 6, Tsukuba, Ibaraki 305-8566 Japan. E-mail: ryo-futahashi@aist.go.jp

14298. Hayashi, F.; Dobata, S.; Futahashi, R. (2004): A new approach to resolve the taxonomic and ecological problems of Japanese *Mnais* damselflies (Odonata: Calopterygidae) (1) General remarks. *Aeschna* 41: 1-14. (in

Japanese, with English summary) ["Several hypotheses coexist about taxonomy of Japanese *Mnais* damselflies (Odonata: Calopterygidae), having some discrepancies on their distributional ranges and ecological consideration. Recent phylogenetic studies based on sequences of the nuclear ribosomal DNA (ITS1 region) suggested that they consist of two closely related species, *M. costalis* and *M. strigata*, with sympatric distributions in a wide range of western Japan. These two species are usually distinguished by wing length:head width ratio and pterostigma length: width ratio of adult males, and also by the caudal gill shape of larvae (Havashi et al., 2004a, b). On the other hand, the sequences of the mitochondrial DNA (COI region) suggested that introgressive hybridization had occurred between the two species because of interspecific similarity (often identical) in mtDNA haplotypes at the same localities (Ilayashi et al., unpublished data). In the present paper, based on this new taxonomic hypothesis, were compared some other morphological characters between the two species, and reviewed their ecological knowledge from literature. The marking pattern on the metapoststemum, that had been used previously to distinguish some populations, varied individually. Both species included individuals with yellow-striped and unstriped metapoststemum, and therefore, this was not a species-specific character. Wing colour patterns also varied among individuals and were polymorphic. The pattern could be divided into three wing morphs; uncoloured (entirely hyaline), partially-coloured (coloured with orange to dark brown at about apical 3/4 area, but hyaline at the basal 1/4), and entirely-coloured (coloured with pale orange nearly all area). All morphs were found in male *M. costalis*, while the entirely-coloured wing morph was rarely found in male *M. strigata*. Females of *M. costalis* consisted, of the two wing morphs, uncoloured and entirely-coloured, but all females of *M. strigata* had uncoloured wings. Males with partially-colored wings are known to territorial fighters and those with uncoloured or entirely-coloured wings are non-territorial sneakers. Males with the latter two wing morphs may mimic females for sneaky copulation around the territorial males. Interspecific combinations of the wing colour morphs differed geographically. Two wing morphs, uncoloured and partially-coloured, were seen in males of both species when living allopatrically. In their sympatric ranges, however, males had completely reciprocal morphs (only partially-coloured wings in *M. costalis* and only uncoloured wings in *M. strigata*) in a part of western Japan, but all morphs coexisted in another part of western Japan. This pattern suggests that a reproductive character displacement occurs between the two species, as already pointed out by Suzuki (1984c). In general, the wing colour and its pattern may be important signals for damselflies to recognize mates by their large compound eyes. If hybrids are at a selective disadvantage, mating between the two species under speciation leads to wasted reproductive effort and, to avoid it, the character displacement is predicted to occur. If speciation goes further and they are completely isolated reproductively, coexistence of interspecifically similar morphs will be allowed. In the future, the mechanisms of

reproductive isolation and differences in the degree of isolation in local populations must be examined experimentally between these two closely related damselflies." (Authors)] Address: Futahashi, R., National Institute of Advanced Industrial Science and Technology (AIST), Central 6, Tsukuba, Ibaraki 305-8566 Japan. E-mail: ryo-futahashi@aist.go.jp

14299. Tsuji, I.; Tosaka, H.; Suda, S.; Futahashi, R. (2004): Records of andromorphic type of *Anax nigrofasciatus nigrofasciatus* Oguma, 1915. *Aeschna* 41: 33-35. (in Japanese, with English summary) ["We found three females of andromorphic type of *Anax nigrofasciatus nigrofasciatus* in the Kanto District in 2003 and 2004. This type was recorded in Taiwan and Nepal but rarely recorded in Japan." 14300. Artemiadou, V.; Lazaridou, M. (2005): Evaluation score and interpretation index for the ecological quality of running waters in central and northern Hellas. *Environmental Monitoring and Assessment* 110(1-3): 1-40. (in English) ["The present study aims at creating an evaluation system for the quality of running waters, based on the analysis of benthic macroinvertebrate records from Hellenic rivers (473 samples from 8 river basins). The proposed evaluation system (Hellenic Evaluation Score and its Interpretation Index) may be used for waters sampled with the cost effective semi-quantitative sampling method of "3 min kick-sweep" and requires benthic macroinvertebrates to be identified to the taxonomic level of family. Though resulting from a modification of the Spanish score BMWP, it differs from it in the following characteristics: a) it includes the relative abundance of benthic macroinvertebrates and b) it takes into consideration the habitat diversity of the studied site, classifying it as "poor" or "rich", based on some parameters of the System B of the Water Framework Directive (2000/60/EU). Its interpretation is also based on a five-scaled classification system, consistent with the provisions of the same Directive." (Authors) Odonata are considered at the family level.] Address: Artemiadou, Vassilia, Laboratory of Zoology, Department of Zoology, School of Biology, Faculty of Science, Aristotle University of Thessaloniki, 54124, Thessaloniki, Greece. 2006

14306. Aydin, G. (2006): Evaluation of insects as bio-indicators for sustainable land use in Çukurova delta. PhD thesis, Inst. Natural and Applied Sciences, Dept Plant Protection, University Çukurova: XXXVI + 269 pp. (in Turkish, with English summary) ["In this research was conducted to use insects as indicator for habitat description, environmental impacts and different human activities within the Çukurova Delta between 2003 and 2004. Hence sand

dune (Km), salt marsh (TB) and salt meadow (TÇ) , forest with *Pinus* sp. (Or), afforestation area with *Eucalyptus* sp. (A), aquatic (S) and beach (Ky) biotopes were evaluated in Çukurova Delta. Natural, semi-natural and unnatural habitats were chosen as 3 different human activity levels under each biotope and sampling methods were used in all sampling areas according to habitat properties. The data included 709 species and 86958 individuals of beetles collected during two years using pitfall trap, sweep, insect net and light trap sampling methods. Indicator species analysis produced to find indicator species for habitat description. In this respect some insect species *Platynemesis dealbata*, *Trithemis arterosia*, *Ischnura elegans ebneri*, *Lestes barbarus*, *Trithemis annulata* and *Orthetrum sabina* were most abundant in aquatic biotope, *Megacephala euphratica euphratica* was most abundant in salt marsh biotope, *Siagona europaea*, *Scarites planus*, *S. subcylindricus*, *Acinopus megacephalus* and *Idaea aversata* were most abundant in salt meadow biotope, *Pimelia bajula solieri* was most abundant in afforestation biotope, *Zophosis dilatata* was most abundant in sand dune biotope and *Lophyridia concolor* was most abundance in beach biotope showed a significant indicator level for habitat description. The analyses of Binomial (present-absent) and Guassian were used by generalized linear modelling produced to find indicator species for human activities. In this respect; 20 species from Coleoptera, 1 species from Hymenoptera, 5 species from Lepidoptera and 4 species from Odonata showed a significant indicator level for human activities such as cattle and sheep/goat grazing (Km, TB, TÇ, A), agriculture land (TB, TÇ, S), tourism (OR, A, Ky), garbage dump (TÇ), cutting and burning plant (Km)." 14320. Chen, X.; Feng, Y.; Chen, Z. (2009): Common edible insects and their utilization in China. *Entomological Research* 39: 299-303. (in English) ["This paper reviews the common edible insects and their use in China. One-hundred and seventy-eight insect species from 96 genera, 53 families and 11 orders are commonly eaten in China. Preparation of edible insects includes frying, braising, stewing, stewing after frying, boiling and roasting. The insect forms eaten range from eggs to adults; however, in restaurants most are larvae and pupae. More than 50 species have been analyzed for their nutritive elements and nutritional value and these data are reviewed here. Insect health foods sold in the Chinese market are also briefly discussed. Six to seven species of dragonfly larvae of Odonata are edible. The common species are *Crocothemis servilia*, *Gomphus cuneatus* and *Lestes praemorsa*. The nutritive elements of three species have been analyzed (Feng et al. 2001b). Naiad is the common stage for eating." - 14327.** Campbell, W.B.; Novelo-Gutiérrez, R.; Gómez-Anaya, J.A. (2010): Distributions of odonate richness and diversity with elevation depend on windward or leeward aspect: implications for research and conservation planning. *Insect Conservation and Diversity* 3(4): 302-312. (in English) ["(1.) Assessing species richness (SR) and diversity along environmental gradients is important to see whether abiotic differences alter patterns of species distribution and composition. (2.) We examined distributions of odonate SR, average taxonomic distinctness (ATD) and functional diversity (FD) (using the Shannon Index on proportions of plant-dependent and non-dependent species) with elevation and slope provided from an exploratory survey along a transect in the Sierra de Coalcomán Mountains, Michoacán State, Mexico. Adults were collected along both sides of a 500 m stream segment for 6 h day⁻¹ site⁻¹ in each of eight sites, and these species lists were complemented by collecting mature larvae. (3.) Species richness and FD declined with elevation among windward sites, while ATD increased. Among leeward sites, SR peaked at mid-elevation, and there was no trend for FD or ATD with elevation. Leeward sites were similar in species composition, whereas windward sites were dissimilar. Slope was correlated with elevation among windward sites, and influenced most variables, but not among leeward sites. FD was negatively correlated with ATD among sites along both aspects. Mean values of SR, ATD and FD between aspects were similar. (4.) The Energy-Richness Hypothesis best explained the species distributions along the windward aspect. Local abiotic influences appeared more important in community assembly among windward sites. Among leeward sites, the potential for Mid-Domain and Rapoport Effects suggest interspecies interactions control community assembly; providing greater potential for expansion of species elevational ranges, and an increase in range expansion of alien and non-endemic species along this aspect." - 14330.** Niesel, J. (2010): Invertebrate occurrence in relation to water permanence and fish in shallow wetlands at Öland, Sweden. MSc. thesis, Dept of Biology and Environmental Science, Senior Lecturer in Biology Univ. of Kalmar: 18 pp. (in English) ["Activity traps were used to study the effects of water permanence and fish predation on the ratio of invertebrate predator and prey species and overall invertebrate abundance in June 2002 in eight shallow calcareous lakes and two small ephemeral water bodies at Öland, southeastern Sweden. The invertebrate predator prey ratio was expected to decrease with decreasing water permanence since invertebrate predators are highly sensitive to drying. Fish was not expected to affect the ratio, since fish selectively feed on large prey species with no care taken to whether the prey is an invertebrate predator or not. The total abundance of invertebrates was expected to decrease both with decreasing water permanence and presence of fish because of drying mortality and selective predation by fish on large invertebrates. Parametric analyses of covariance (ANCOVA) on the lake data revealed no significant effect of fish or maximum depth (used as a measure of permanence) on the ratio of invertebrate predators and prey in the studied wetlands. Fish significantly negatively affected the invertebrate abundance and the mean abundance was twice as high in fishless wetlands as in wetlands with fish. The significant fish effect is however dependent on only one value and is therefore no longer significant when the interaction variable is excluded in the analysis. Maximum depth did

not significantly affect the abundance even if the relationship was close to significant. Since both maximum depth and the interaction variable were close to significant, increased replication of fishless wetlands might produce significant effects of these variables on the invertebrate abundance. Although tench (*Tinca tinca*) is an effective benthic forager, the overall invertebrate abundance was not more affected in the one local with tench than it was in the other wetlands with northern pike (*Esox lucius*). This indicates that one cause of the decrease in waterfowl density and diversity observed during the 20th century might be found in the benthic invertebrate community (e.g. chironomids and others)." (Author) The list of taxa includes Lestidae indet., Aeshnidae indet., and Libellulidae indet.] Address: not stated

14331. Popova, O.N. (2010): The dragonfly larvae population (Odonata) in a temporal water pond. Eurasian Entomological Journal 9(2): 239-248. (in Russian, with English summary) ["The structure and seasonal dynamics of the Odonata population of a temporary pond in Baraba forest-steppe (SW Siberia, Russia) are presented. Despite the extreme instability and poor conditions prevailing in the pond, the population is taxonomically rich (21 species), composed of a large number of individuals, resulting in high odonate biomass compared to that of the other aquatic insects. The adaptations for survival in temporary ponds for Odonata are discussed." (Author)] Address: Popova, O.N., Inst. Anim. Syst. & Ecol. Russ. Acad. Sei, Frunze 11, RUS-630091 Novosibirsk

14332. Qin, C.-H.; Yao, L.; Chen, C.; Zhang, C.-C.; Li, J.-H. (2010): Insect community structures and dynamics analysis in different aquatic vegetable areas in Wuhan. Chinese Bulletin of Entomology 47(1): 76-81. (in Chinese, with English summary) ["The insect community structure in different types of aquatic vegetables in Wuhan (Hubei province, China) were investigated with visual method and net method from May to October of 2008. The results showed that there were 9 169 individuals belonging to 11 orders, 48 families, 104 species. *Rhopalosiphum nymphaeae* (L.), *Prodenia litura* (Fabricius), *Saccharosyne procerus* (Matsumura), *Scirpophage praelata* (Scopoli) and *Galerucella birmanica* (Jacoby) were the main pests, and Odonata (*Agriocnemis femina*, *Crocothemis servilia*, *Ischnura senegalensis*, *Acisoma panorpoides*) and Coccinellidae were the primary natural enemies. The analyses on community structure indicated that the diversity index of insect community were remarkably different in different vegetations, which was the highest in water dropwort, and was the lowest in lotus. Insect community structure on water dropwort was the most stable, and water chestnut was at the second place. The diversity index of insect community in lotus was high in middle period, but low in early and late periods, whereas that in water bamboo was low in middle period, but high in early and late periods." (Authors)] Address: Qin, C.-H., College of Plant Science and Technology, Huazhong Agricultural University, Wuhan 430070, China

14333. Rowan, B. (2010): Nine years on: Revisiting the pond communities of the Lizard Peninsula, UK. The Plymouth Student Scientist 3(2): 40-59. (in English) ["Ponds contribute in various amounts to freshwater biodiversity and in some regions can be of considerably high biodiversity value compared to other freshwaters. The ecology of pond communities has been studied by numerous authors, yet many of these studies represent only a snapshot in time. This study explored the macroinvertebrate communities of a selection of ponds on the Lizard Peninsula, UK and revisited these ponds after a nine year period, examining changes in composition, environmental variables structuring the communities and their conservation value. Ponds in both years formed distinct groups, based on community similarities. In both years area was an important environmental variable structuring the communities and in the first year visited water chemistry and number of plant species also contributed. Between the two years the number of macroinvertebrate species remained similar, 72 in 2000 and 74 in 2009, but the identity of the species within the pond communities differed. The conservation value of the pond communities between the two years did not significantly differ. With regards to conserving these Lizard ponds, turnover in ponds has not affected their biodiversity value and management should allow for such processes to take place." (Author) *Lestes sponsa* is the single odonate species mentioned.] Address: Rowan, B., School of Marine Science & Engineering, University of Plymouth, Drake Circus, Plymouth, PL4 8AA, UK

14338. Buckland-Nicks, A.H. (2011): Mercury bioaccumulation in dragonflies (Odonata: Anisoptera) from two lakes in Kejimikujik National Park Nova Scotia. Bachelor of Science thesis, Acadia University: xi, 105 pp. (in English) ["Mercury biomagnification is a concern due to neurotoxic effects in higher trophic organisms. Dragonflies (Odonata: Anisoptera) are vectors for MeHg in aquatic and terrestrial food chains. Dragonfly naiads, adults, and exuviae were collected from two lakes in Kejimikujik National Park, Nova Scotia. Samples were dried, digested, and analyzed for methylmercury (MeHg), divalent mercury (Hg(II)), and total mercury (THg) using gas chromatography-atomic fluorescence spectroscopy (AFS). Big Dam West lake dragonfly samples had greater MeHg, Hg(II), and THg than Big Dam East; reflecting higher water mercury concentrations and indicating potential as biomonitors. MeHg concentrations in naiads (n=64) ranged widely (mean: $0.2337 \pm 0.1129 \mu\text{g g}^{-1}$) and %MeHg was high (mean: $92\% \pm 4\%$). Adults (n=28) had similar dry weight MeHg but higher wet weight MeHg and THg, and lower %MeHg than naiads. Exuviae (n=32) had 50-fold lower MeHg than naiads and adults but nearly equal Hg(II). Emerging adults had similar MeHg to naiads and mature adults; however, they had between 1.5 and 3-fold higher Hg(II). Bioaccumulation patterns of Hg(II) in dragonfly life stages may provide information on MeHg detoxification. MeHg and THg increased with naiad age and weight, with a large increase in variation. Oldest and heaviest naiads had both the lowest and highest MeHg. Hg(II) had an opposite pattern to MeHg, with concentrations and variation decreasing with age and weight. Results indicate that dragonflies may have mechanisms of MeHg detoxification; however, they still have a high potential for transferring substantial amounts of MeHg to aquatic and terrestrial food chains." 14339. Cardoso, P. (2011): Habitats Directive species lists: urgent need of revision. *Insect Conservation and Diversity* 5(2): 169-174. (in English) ["(1.) The European Habitats Directive is the main legislative work regarding Europe's nature conservation policy. It lists the protected habitats and species in the European Union. The species lists include 122 arthropods. (2.) The current lists of arthropods (Annexes II and IV) present, possibly among other, five obvious biases: taxonomic, geographic, range, size and aesthetic biases. Species of selected taxa (Lepidoptera, Coleoptera, Odonata and Orthoptera), from Northern or Central Europe, relatively widespread, of a large body size and attractive are favoured over species of other taxa,

from southern and Mediterranean Europe, endemic or relatively small or inconspicuous. Such biases are obstacles to the effective protection of the European fauna. (3.) Two main strategies should be followed to avoid these problems and therefore increase the effectiveness of conservation policies: (i) the adoption of objective and transparent criteria for the listing of protected species, and (ii) implement regular updates and amendments to the lists based on such criteria." (Author)] Address: Cardoso, P., Smithsonian Institution, National Museum of Natural History, Washington DC, USA

14340. Corso, A. (2011): Migrating dragonflies as a food source for breeding Eleonora's Falcons and migrating raptors. *British Birds* 104: 670-675. (in English) ["In July 2009, during the boat trip from Lampedusa to Lampione (Italy, Mediterranean Sea), we encountered many migrant dragonflies at sea, mostly *Anax ephippiger* and *Sympetrum fonscolombii*. As we approached Lampione we realised that several Eleonora's Falcons *Falco eleonora*, which breed on the island, were actively hunting the dragonflies, which they caught readily in flight. Similar behaviour has previously been documented at other Sicilian sites, including Lampedusa, the Eolie Archipelago and Pantelleria (Lo Cascio 1999; pers. obs.). Lampione is a small islet (700 m x 180 m) and, compared with larger islands, attracts relatively few passerines during migration. At times when avian prey is scarce or absent, it seems likely that migrating dragonflies constitute an important food source for Eleonora's Falcons during the breeding season." 14342. Farkas, A.; Jakab, T. (2011): Data on the dragonfly (Odonata) fauna of the floodplain area Borsodi-Tisza-hullámter (NE-Hungary). *Studia odonotol. hung.* 13: 89-96. (in Hungarian, with English summary) ["The paper presents faunistical data on dragonflies (larvae, exuviae and adults) (*Stylurus flavipes*, *Gomphus vulgatissimus*) collected along the impounded reach of the River Tisza in the floodplain area Borsodi-Tisza-hullámter (a geographical microregion inside the mesoregion Közép-Tisza-vidék, NE-Hungary). Firstly the authors present the methods em-

ployed in the collection of the specimens and in data processing, and introduce the literature considered in the identification of species and in reporting faunistic data. Thereafter they provide a detailed survey of the faunistic results from the sampling sites and finally summarize and evaluate the data on the dragonfly fauna. Collections were made in 1 year (2009), with the participation of 1 specialists on 31 days and 6 localities altogether, in 3 cells (DT 87, DT 88, DT 89) of the 10×10 km UTM grid map. In the report information on 3311 specimens (with undetermined sex) is given in detail (3289 exuviae; further 10 larvae and 12 adults collected as dead specimens), representing altogether 202 faunistic data (10 larvae, 180 exuviae, 12 adults). In this study 2 species (2 Anisoptera) were recorded in the area out of which 1 belongs to the less frequent and 1 to the rare class of country-wide occurrence frequency." (Authors)] Address: Farkas, Anna, Department of Hydrobiology, Centre of Arts, Humanities and Sciences, Faculty of Science and Technology, University of Debrecen, Egyetem tér 1, H-4032 Debrecen, Hungary. 14343. Farkas, A.; Jakab, T.; Devai, G. (2011): Emergence behaviour of riverine dragonfly (Odonata: Gomphidae) larvae along the Tisza river system based on exuviae surveys. *Acta Biol. Debr. Oecol. Hung.* 26: 53-66. (in Hungarian, with English summary) ["Emergence behaviour of riverine gomphid larvae, i.e. emergence distance, selection of emergence support and mortality during emergence are discussed. The study was based on the systematic collections of exuviae at reaches of the rivers Tisza and Szamos with different characteristics. Notes were made about the chosen emergence structure and the distance from the water line. In addition, mortality events were also recorded at the river reach at Tiszafüred characterized by the highest abundance of gomphids. Based on our results the larvae of the studied species differ significantly in their distance travelled from the water line to the emergence site. It was confirmed, that among the studied gomphid species the larvae of the earliest emerging *G. vulgatissimus* move away the farthest from the water line. According to our data, the distance crawled by the larvae to the emergence site correlates positively with the water level and negatively with the water temperature. At a given river reach the ratios of supports chosen by the larvae were similar in the different species, while in the same species it varied in higher degree between the studied river reaches. Thus, support-selection for emergence was primarily dependent on the frequency of structures and the distance crawled from the water line. At Tiszafüred bird predation on the abundant *G. flavipes* caused significant mortality. In contrast, in the case of *G. vulgatissimus*, emerging in small numbers, mortality was found to be negligible." 14350. Pham, T.T. (2011): A real-time neural signal processing system for dragonflies. MSc. thesis, Dept Electrical & Computer Engineering, University of Arizona: 93 pp. (in English) ["This thesis focuses on hybrid bio-robotics (robots incorporating living animals as sensors) and visual electrophysiology in insects. The motivation of this study is solving a current problem of perception in neuromorphic systems. When imitating biological sensors, we have not completely understood the early processing of the input to reproduce artificially. Building hybrid systems with both artificial and real biological components is a promising solution. In hybrid bio-robots using a dragonfly as a living sensor, the early processing of visual information is performed fully in the brain of the dragonfly. The only significant remaining tasks are recording neural signals and processing, along with interpreting neural information in software and/or hardware for a robot platform. Based on existing works which focused on recording neural signals,

this thesis adds a software application of neural information processing to make a visual processing module for dragonfly hybrid bio-robots. After a neural signal is recorded in real-time, spikes of this signal can be detected either promptly by a hardware module using a simple threshold-based detection method or more accurately by a software module using an energy-based detection algorithm. Features of spikes are then extracted using a wavelet decomposition method. Finally, the system matches spikes with templates to find relevant neurons. The output of the whole visual processing module will be used to control other parts of a dragonfly hybrid bio-robot." (Authors)] Address: Pham, Thuy T., Dept of Electrical and Computer Engineering and Department of Neuroscience, University of Arizona, AZ USA 85716

14351. Szalay, P.E. (2011): Book review [BROOKS, S. (edit.) 2010: Field guide to the dragonflies and damselflies of Great Britain and Ireland. 4th revised edition. – British Wildlife Publishing, Gillingham, 160 pp. *Studia odonatol. hung.* 12: 93-95. Szalay, P.É.; Gyulavári, H.A.; Szabó, L.J.; Miskolczi, M.; Cserhádi, C.S.; Dévai, G (2011): Comparative morphometric analysis of male adults of small red-eyed damselfly (*Erythromma viridulum* CHARPENTIER, 1840) collected from four North-East Hungarian populations. *Studia odonatol. hung.* 12: 5-32. (in Hungarian, with English summary) ["Our objective was to develop a reference baseline for this species of discussed taxonomical status relying on populations from the Pannonian Ecoregion, in order to provide a starting point for later comparisons. Specimens were collected at four NE-Hungarian water bodies representing different types. For each population 16 body marks and 9 wing marks in 15 male adults were analysed, respectively. The mean, minimum, maximum and deviation values; the difference between the minimum and maximum values relative to the mean, as well as the coefficients of variation were calculated. The position of the populations was described via principal component analysis and cluster analysis supported by KRUSKAL&WALLIS and MANN&WHITNEY tests. The strength of correlation between the marks was evaluated via linear regression analysis. Our results suggest that on the basis of all marks and wing marks the population from Kati-ér is the most distinct, whilst individuals from Bodzási-nyágyödrök or Tisza-hullámtér differ most considerably from the other three populations on the basis of body marks." 14355. Vajda, C.; Szabó, L.J.; Miskolczi, M.; Devai, G. (2011): The morphometry of adult Southern Emerald Damselfly [*Lestes barbarus* (FABRICIUS, 1798)] based on the study of a population in North-East Hungary. *Studia odonotol. hung.* 13: 5-25. (in Hungarian, with English summary) ["There is very few data in the literature about the morphometry of dragonfly species including *Lestes barbarus*. Our work aimed at increasing the amount of data concerning this species, exploring the variation in the focal marks and comparing the sexes. The study is based on the body- and wing-marks of 15 male and 15 female adults from the marsh Fancsikai-mocsár, North-East Hungary. We measured the following parameters: total body length, total abdomen length, five marks on the head, two on the legs, 12 on the anal appendages of the males and seven on the abdominal tip of the females. We measured the area of the wings and the distance between eight selected points on them. The cross-veins in three rows of cells and the cells in eight rows of cells were counted as well. We used not only the mean, SD, maximum and minimum values to the comparison, but the coefficient of variation and the difference between the minimum and maximum values relative to the mean values. Furthermore we used SHAPIRO & WILK, Student-t and MANN & WHITNEY tests, principal component analysis, canonical discriminant analysis and linear regression between selected

marks. We found that total body length and total abdomen length of the males were significantly larger than the females', although females were significantly larger in the marks of head, legs and in wing-size. In case of the body-marks, variance was more significant in the abdominal tip. Considering the wings, larger differences were found in the number of cross-veins and cells. Principal component analysis showed a slight overlap in the convex hull of the body-marks and the wing-sizes of the two sexes, while discriminant analysis showed a full separation in both cases. Linear regression showed highly significant correlation for 20 mark-pairs but found no significant correlation in 68 cases. The total body length showed the maximal number of highly significant correlations, while the most numerous correlations with the different marks were at the head's marks." (Authors)] Address: Vajda, C.S., Department of Hydrobiology, Centre of Arts, Humanities and Sciences, Faculty of Science and Technology, University of Debrecen, Egyetem tér 1, H-4032 Debrecen, Hungary

14362. Buczynski, P. (2012): Dragonflies (Odonata) of the left-bank Bug River valley between Włodawa and Kodeń (middle-eastern Poland). *Zeszyty naukowe uniwersytetu Szczecińskiego NR 728 Acta Biologica* 19: 47-69. (in English, with Polish summary) ["The presented paper analyses the occurrence of dragonflies in the left-bank (Polish) part of the Bug River valley between Włodawa and Kodeń (65 km of the river course, 51°32'–51°55' N, 23°31'–23°38' E). In total, 40 species were recorded. The key sites for dragonflies were oxbow lakes, the Bug River and its tributaries. Species diversity was found to be relatively low due to a lack of peatlands and dystrophic waters, as well as strong eutrophication of small water bodies. The effects of strong water pollution in the Bug River were evident. The species composition of dragonflies was typical, but densities of Gomphidae (particularly *Ophiogomphus cecilia*) suggested an adverse state of the environment. This is caused by surface runoffs of agricultural wastewater in Poland, but also by strongly polluted rivers in the territory of Ukraine. The study includes a review of earlier research conducted in the upper course Bug River valley. Considering both the old and new data, 54 dragonfly species were recorded in the Middle Bug River valley between

Golêbie and Kodeń (246 km of the river course at the border of Poland with Ukraine and Belarus). It is an area of high importance for the protection of dragonflies in terms of species diversity and species assemblages." (Author)] Address: Buczynski, P., Dept of Zool., Maria Curie-Skłodowska University, Akademicka 19, PL-20-033 Lublin, Poland. E-mail: pawbucz@gmail.com

14364. Eggers, J.T. (2012): Effects of substrate on habitat selection by libellulid dragonflies. Ms. thesis, Northern Illinois University: 88 pp. (in English) ["Habitat selection is a complex process with both biotic and abiotic factors acting to influence the habitat a species occupies. Larvae of the odonate family Libellulidae are predominantly benthic, although some species are frequently associated with vegetation rooted in the sediments. The purpose of this study was to investigate how sediment type influences habitat selection in larvae of four libellulid species: *Pachydiplax longipennis*, *Libellula quadrimaculata*, *Tamea lacerata*, and *Libellula luctuosa*. Another aim was to investigate the influences of vegetation, prey availability, and predators on habitat selection. Both laboratory and field data were utilized in this study. The laboratory research consisted of eight experiments. Experiments 1–4 were designed to determine if sediment type was a factor in habitat selection in the presence and absence of different vegetation types. Experiment 5 and 6 examined the influence of prey availability and hunger with respect to sediment and vegetation. To determine if characteristics of a habitat alter the larva's response to a predator, Experiment 7 was designed to expose larvae to different combinations of sediment and vegetation with and without a predator present. Experiment 8 examined influences of sediment type in early instar larvae habitat selection. Field data was obtained via dragonfly larval sampling from May to October 2011. In laboratory experiments, libellulid larvae discriminated among sediment despite influences from other factors such as vegetative structure, prey availability, and predator presence. Whether the simulated vegetation was with screening or plants, larvae were found significantly more often with vegetation than bare soil with the exception of *L. quadrimaculata*. With the addition of a predator, all species of larvae were observed closer to the predator cage when on the previously established "preferred" soil

type than when on the other sediments. With the addition of prey, there was no difference in habitat selection between starved and fed individuals except in the case of *P. longipennis*. The most distinct similarity in the results for all four species was a significant avoidance of sand. Field data showed that the four species in this study demonstrated non-random association with substrate. The larvae species studied were found most often in natural sites that reflected the established "preferred" substrate from lab experiments, except in the case of *T. lacerata* larvae. For *T. lacerata*, substrate composition may be less important in habitat selection than other factors." (Author)] Address: Eggers, Jennifer Terese,

14365. Farkas, A.; Móra, A.; Devai, G. (2012): Mortality during emergence in *Gomphus flavipes* and *G. vulgatissimus* (Odonata: Gomphidae) along the Danube. *Acta Biol. Debr. Oecol. Hung.* 28: 65-82. (in Hungarian, with English summary) ["The mortality during emergence of the two closely related Hungarian Gomphus species was studied along the branches of the River Danube surrounding the island Szentendrei-sziget. Exuviae, dead and damaged specimens as well as dragonfly wings left behind by birds were collected daily to quantify the rates and the causes of mortality. The mortality rate remarkably differed between the species, such as the factors contributing to mortality. Total mortality during emergence proved to be relatively low in both species, but it was nearly two times higher (6.37%) in *G. flavipes* than in *G. vulgatissimus* (3.4%). In *G. vulgatissimus* mortality was mainly attributed to predation (1.36%) and natural physical factors (1.36%), particularly weather conditions. Whereas, in *G. flavipes* predation and artificial waves (generated by watercrafts) accounted for the major part of mortality (3.44% and 2.16% respectively). Our results suggest that the differences between the two species in mortality are in relation with the population size and the emergence strategy. Although the artificial waving influenced a small proportion of *G. flavipes* population, it should be considered as an important factor in point of view of nature protection." (Authors)] Address: Farkas, Anna, Dept of Hydrobiology, Centre of Arts, Humanities and Sciences, Faculty of Science and Technology, University of Debrecen, Egyetem tér 1, H-4032 Debrecen, Hungary. 14370. Geraeds, R.; Muusse, T.O.V. (2012): The rediscovery of *Coenagrion mercuriale* in the Dutch province of

Limburg. *Brachytron* 15(1): 25-3. (in Dutch, with English summary) ["*C. mercuriale* has always been rare in the Netherlands. Only two reliable sightings are known: in 1903 and 1926. However, on the 1st of June 2011, four or five male Southern damselflies were found in the Beesels Broek in the Dutch province of Limburg. In the following days. Southern damselflies were seen almost daily up and until the 13th of June; after the 13th none were spotted. Only males were seen, maximally five animals at a time. All animals were seen along a small part of the Huilbeek brook and a small seepage stream. Both streams do not look wry suitable for the species. There is a lack of submerged vegetation that is suitable as larval habitat. Besides that, the Huilbeek brook is densely grown with *Phragmites australis*. Because of this, and the short 13-day period (early in the flight period that animals were seen), it is possible that there is no population present in this area of the Beesels Broek. It is most likely that the damselflies are vagrants from a nearby (undiscovered) population." (Authors)] Address: Geraeds, R.P.G., Bergstraat 70, NL-6131 AW Sittard, The Netherlands

14371. Geraeds, R. (2012): Habitat of larvae of *Gomphus vulgatissimus* in some streams in the Dutch province of Limburg. *Brachytron* 15(1): 3-15. (in Dutch, with English summary) ["The locations and timing of emergence of Gomphidae in the river Rur have been thoroughly investigated in recent years. It is assumed that gomphid dragonflies generally emerge close to their larval habitat. Since surveys of actual larval habitats in the Netherlands have been very rare, four transects of the Rur were checked for the presence of larvae of Common Clubtail (*Gomphus vulgatissimus*) during the years 2006-2009. The aim of this study was to discover what type of substrate the larvae prefer, and if the places where the dragonflies emerge are indeed situated close to the actual larval habitats. The larvae were caught with a hand brailer, which is normally used for fish and amphibian surveys. For each of the larvae caught, the type of substrate in which it was caught and its distance to the river bank were noted. Most of the 615 larvae were found within one metre distance of the river bank, and almost 50% even within 0,5 metre from the bank. The largest distance from the bank at which larvae were caught was 5 metres. Most larvae were found in mixed substrates, dominated by a combination of silt and detritus. Only a few larvae were found in substrates dominated only by silt, detritus, sand or gravel. Because the river Rur is too deep to investigate the whole streambed, it was not certain if the results were a good representation of the actual situation. Therefore, in 2009 and 2010 three smaller streams were investigated, using the same method as in 2006-2009. During this period, 51, 108 and 62 larvae were caught in the rivers Swalm, Vlootbeek and Worm respectively. These results were similar to the situation in the river Rur. In the three streams most larvae (53% to 63%) were caught within 0,5 metre from the bank as well. Same as in the Rur most larvae were found in mixed substrates, which were dominated by a combination of silt and detritus. In substrates that consisted of just

one type, almost no larvae were caught. Most likely, the preference for locations near the river banks is a result of the greater diversity in types of substrate. Further up the streambed, the streaming velocity is too high for sedimentation of silt and detritus. Therefore, the diversity of types of substrate is much higher along the banks. The majority of larvae of *Gomphus vulgatissimus* were found close to the banks, and it is most likely that they emerge near the larval habitat." 14375. Joger, U.; Dujsebayaeva, T.; Belyalov, O.V.; Chikin, Y.; Guicking, D.; Grachev, Y.A.; Kadyrbekov, R.; Miaud, C. (2012): Fauna of the Aralkum. In: Breckle, S.W., W. Wucherer, L.A. Dimeyeva & N.P. Ogar (eds.): *Aralkum - a man-made desert. The desiccated floor of the Aral Sea (Central Asia)*. *Ecological Studies* 218: 199-269. (in English) ["The fauna of the Aralkum has been studied only partly. But the lists of mammals of the Kazakhstan part of the Aral Sea region, the migratory breeding bird species and rare winter visitors, the resident breeding bird species, passage visitors (birds), vagrant birds, reptiles collected around Aral Sea in 2002-2004, and taxonomical diversity of insect orders and other groups are documented. The ecological disaster of the Aral Sea reduced the faunistic diversity of the area in a selective manner. Aquatic and semiaquatic animal species such as fish-eating birds, waterfowl, Amphibia, water snakes and aquatic insects suffered dramatic reductions in numbers. Some freshwater

species and species of riverine forest died out or left the area completely. On the other hand, desert species and certain eurybionts were able to extend their ranges into the Aralkum. Further monitoring of the fauna of the Aralkum is strongly recommended to document the very active migrations to and invasions of the dynamic new ecosystems." (Author) In table 11.13 *Ischnura aralensis*, *Calopteryx virgo*, *Anax imperator*, *Orthetrum sabina*, and *Selysiothemis nigra* are classified as "Rare insect species of the Aral Sea".] Address: Joger, U., Staatliches Naturhistorisches Museum, Pockelsstr. 10, 38106 Braunschweig, Germany. (2012): Morphometric study of an adult Dark Emerald Damselfly [*Letes macrostigma* (Eversmann, 1836)] population from a Hungarian alkaline pond. *Studia odonotol. hung.* 14: 81-102. (in Hungarian, with English summary) ["Although exact information about different species are necessary for ecological and hydrobiological researches we found very few about the *L. macrostigma*. So our aim was to provide more information concerning this species. Furthermore we explored the variation of the examined body and wing traits and compared the sexes. The study is based on male and female adults collected from a Hungarian alkaline pond (Kelemen-szék) in the area between the rivers Danube and Tisa. Our results showed that males had larger body than females however this difference was not significant. Females nevertheless had significantly bigger head and wings. The multivariate analysis could not divide the sexes clearly based on body traits, but based on the wing measurements. Interestingly the traits of the head was correlated mostly with other traits." 14389. Adriaens, D.; Adriaens, T.; De Knijf, G.; Hendrickx, F.; Maes, D.; Van Landuyt, W.; Vermeersch, G.; Louette, G. (2013): Soorten en biotopen in Oost-Vlaanderen: prioriteit en symbolwaarde voor het natuurbeleid. *Rapporten van het Instituut voor Natuur- en Bosonderzoek 2013* (1040772). Instituut voor Natuur- en Bosonderzoek, Brussel: 387 pp. (in Dutch, with English summary) ["Many species and biotopes are struggling to survive in the Flemish region of Belgium, an area that is highly impacted by human presence. Nature policy tries to halt the current biodiversity crisis by implementing both area and species based conservation measures. Area based conservation measures aim to guarantee a minimum level of quality that serves a broad spectrum of species and biotopes. This is achieved by creating a broad network of areas and managing them in favour of biodiversity. However, for several nature values these area based measures do comply only partially or not at all with their ecological requirements. They also need habitat features that lie outside protected areas. In this case, additional and specific measures are needed to protect particular species and biotopes from disappearing. While the Flemish regional government mainly adopts an area based approach by setting apart nature reserves, the provincial governments (5 in Flemish region) rather focus on conserving biodiversity outside the network of nature reserves. For the latter, an extensive set of measures is required, tailored to the specific needs of species and biotopes. As they are applied outside protected areas, public support is a critical success factor. Indeed, not only provincial and local authorities have their role to play, but also individual citizens can contribute to the conservation of biodiversity. Both financial and logistic means to stop the biodiversity crisis are limited, however. Therefore, priorities have to be set: for which species and biotopes are conservation measures most urgent. It is obvious that provinces with a large share of the distribution or population of threatened nature values, bear a large responsibility for the conservation at the regional, national and even European level. With the finalisation of this report, each province in Flanders now has a list of species for which they contribute most to their conservation. These lists share a common methodology. Hence, they ensure that if the appropriate measures are applied, each province contributes to the maximal extent to the halt of biodiversity loss. In addition, and for the first time, this report also makes a prioritisation of the biotopes (in fact these are spatial units with specific environmental characteristics and a corresponding set of species) in the province of Eastern Flanders, based on area covering inventories in Flanders (Biological Valuation Map). The adopted methodology can easily be applied to make a list of the most

important biotopes in each of the other provinces of Flanders too. In this report, 155 species are listed as important biodiversity values for which the province of Eastern Flanders can further elaborate its biodiversity policy. Species were selected among 10 taxonomical groups. About one third of the species are present with more than a third of their Flemish distribution or population within the boundaries of the province of Eastern Flanders, or at least their share is higher as expected compared with the other provinces. Moreover, these species are among the most threatened in Flanders and are thus considered to take the most advantage of conservation measures. They are called priority species for the province. The other two thirds of the 155 species can be seen as symbol species for several other reasons. For example, they are explicitly protected by European legislation or are currently facing a steep decrease in numbers, extent or area of occupancy. Other species especially take advantage of the efforts to connect the actual nature reserves by creating stepping stones and corridors in the intervening landscape, a task for which the provincial government is qualified. Also species with most of their distribution or population size within the provincial territory are listed as symbol species. Analogously, about 20 biotopes with high importance within the province of Eastern Flanders were selected. They cover a broad spectrum: from mud flats and salt marshes, over creeks, wetlands, grasslands and tall herbs, to shrub and woodlands. Small landscape elements like rows of trees or shrub, embankments, fortresses and bunkers are considered as well. The choice of species and biotopes is consolidated by recent, objective and trustworthy data. The ecology, distribution, threats and conservation measures are described for each of the biodiversity values. The degree to which the distribution or population is spatially covered by nature reserves or areas with nature oriented management is determined too and can be used as an extra criterium to decide upon the sense of urgency for conservation action. The compilation of a list of species and biotopes of high conservation priority at the provincial level is an essential step in the design of a strategic policy that aims to spend the available funds as efficiently as possible for the conservation of biodiversity." (Authors) The following odonate species are treated in detail: *Cordulegaster boltonii*, *Coenagrion pulchellum*, *Aeshna isoceles*, *Libellula fulva*, *Leucorrhinia pectoralis*, *Calopteryx virgo*, and *Somatochlora flavomaculata*] Address: Knijf, G. de, Instituut voor Natuurbehoud, Kliniekstraat 25, B-1070 Brussel, Belgium. 14391. Baa-Poku, J.; Asante, F.; Amakye, J.S. (2013): Impact of urban effluents on the macroinvertebrates of a

creek in Accra, Ghana. *West African Journal of Applied Ecology* 21(1): 97-109. (in English) ["Five study stations were selected along the reaches of the creek. Water and benthic samples were collected and analyzed between September 2005 and February 2006. The study showed that the effluent discharges caused a significant increase in BOD, COD and NH₃ at the stations that received the effluents. The high levels of total and faecal coliforms at the midstream sections of the creek (626.0 x 10⁴ cfu/100 ml and 75.30 x 10⁴ cfu/100 ml, respectively) indicated increased pollution levels compared to the reference stations (446.0 x 10³ cfu/100 ml and 133.0 x 10³ cfu/100 ml). The Nima Creek showed characteristics of a disturbed urban creek. A total of 19 macroinvertebrate taxa, comprising a total of 11,613 individuals, were collected. Estimated Shannon-Weiner Diversity Index (H') was low at the midstream section of the creek, H' = 1.14, where the effluents were concentrated than at the upstream H' = 1.44 or downstream H' = 1.38 sections of the creek. Chironomina and Physa were the most abundant taxa within the creek, dominated by the genus *Chironomus*, which is known to be tolerant to pollution, which confirmed the polluted state of the creek. Rigorous and regular assessment and monitoring of effluents from waste treatment plants and other sources that discharge into the creek, with the aim of complying with the Environmental Protection Agency (EPA) guidelines are some of the mitigative measures suggested to protect life in the creek." 14392. Baird, I.R.C.; Burgin, S. (2013): An emergence study of *Petalura gigantea* (Odonata: Petaluridae). *International Journal of Odonatology* 16(3): 193-211. (in English) ["Emergence studies in Odonata provide information on the behaviour, ecology and fundamental demographic parameters in population studies. This paper reports on a study of sex ratio at emergence, pattern and duration of the emergence season, and potential cohort splitting in *Petalura gigantea*. Sex ratio at emergence varied among years, habitat patches and swamp types. Across all collections, sex ratio varied significantly from a 1:1 ratio, with a bias towards females. The duration of the emergence season varied between sites and years, from at least 45 to at least 70 days, potentially commencing by late October and extending into early January and possibly beyond. Although some evidence suggested cohort splitting, it was not confirmed. Observations of spatially and temporally aggregated emergence clusters are consistent with observed oviposition patterns of individual females, suggesting cohort emergence. Observations of mortalities at emergence and of emergence location are provided; the latter should assist researchers and resource managers in identifying breeding sites in heterogeneous swamp vegetation." 14393. Brown, J.R.; Müller, T.; Kerby, J.L. (2013): The interactive effect of an emerging infectious disease and an emerging contaminant on Woodhouse's toad (*Anaxyrus woodhousii*) tadpoles. *Environmental Toxicology and Chemistry* 32(9): 2003-2008. (in English) ["Two factors influencing amphibian population declines are infectious diseases and exposure to anthropogenic contaminants. We examined an emerging fungal pathogen, *Batrachochytrium dendrobatidis* (Bd), and its interaction with an emerging contaminant, the antimicrobial triclosan. We first conducted, a two x two x four factorial study to examine the interactive impacts of dragonfly predator cues, Bd, and triclosan (0, 10, 100, 1000µg/L) on Woodhouse's toad tadpoles. We measured the lethal and sub-lethal impacts of these stressors on tadpoles over four weeks. All tadpoles in the 100 and 1000µg/L concentrations of triclosan died within 24h of exposure, but tadpoles in the low concentration (10µg/L) survived. Tadpoles exposed to only Bd (no triclosan) exhibited a low survival rate (67.5%) while those exposed to both 10µg/L triclosan and Bd exhibited a high survival rate (91.1%) implying that triclosan inhibits Bd on tadpoles. Bd and predator cue exposure individually increased the developmental rate of the surviving tadpoles but this effect was absent when these factors were combined with triclosan. In a follow-up study we found Bd growth in culture was significantly inhibited at 10µg/L concentration of triclosan and completely inhibited at 100µg/L. These findings suggest that interactions among multiple stressors can be complex and require examination in conjunction with one another to evaluate actual impacts to aquatic fauna."(Authors)] Address: Brown, Jennifer, Dept of Biology, University of South Dakota, Vermillion, SD, USA. 14394. Combes, S.A.; Salcedo, M.K.; Iwasaki, J.M.; Pandit, M.M. (2013): Capture success and efficiency of dragonflies pursuing different types of prey. *Integrative and Comparative Biology* 56(5): 787-798. (in English) ["The dynamics of predator-prey interactions vary enormously, due both to the heterogeneity of natural environments and to wide variability in the sensorimotor systems of predator and prey. In addition, most predators pursue a range of different types of prey, and most organisms are preyed upon by a variety of predators. We do not yet know whether predators employ a general kinematic and behavioural strategy, or whether they tailor their pursuits to each type of prey; nor do we know how widely prey differ in their survival strategies and sensorimotor capabilities. To gain insight into these questions, we compared aerial predation in 4 species of libellid dragonflies pursuing 4 types of dipteran prey, spanning a range of sizes. We quantified the proportion of predation attempts that were successful (capture success), as well as the total time spent and the distance flown in pursuit of prey (capture efficiency). Our results show that dragonfly prey-capture success and efficiency both decrease with increasing size of prey, and that average prey velocity generally increases with size. However, it is not clear that the greater distances and times required for capturing larger prey are due solely to the

flight performance (e.g., speed or evasiveness) of the prey, as predicted. Dragonflies initiated pursuits of large prey when they were located farther away, on average, as compared to small prey, and the total distance flown in pursuit was correlated with initial distance to the prey. The greater initial distances observed during pursuits of larger prey may arise from constraints on dragonflies' visual perception; dragonflies typically pursued prey subtending a visual angle of 1°, and rarely pursued prey at visual angles greater than 3°. Thus, dragonflies may be unable to perceive large prey flying very close to their perch (subtending a visual angle greater than 3–4°) as a distinct target. In comparing the performance of different dragonfly species that co-occur in the same habitat, we found significant differences that are not explained by body size, suggesting that some dragonflies may be specialized for pursuing particular types of prey. Our results underscore the importance of performing comparative studies of predator-prey interactions with freely behaving subjects in natural settings, to provide insight into how the behaviour of both participants influences the dynamics of the interaction. In addition, it is clear that gaining a full understanding of predator-prey interactions requires detailed knowledge not only of locomotory mechanics and behaviour, but also of the sensory capabilities and constraints of both predator and prey." 14398. Degabriele, G. (2013): An overview of the dragonflies and damselflies of the Maltese Islands (Central Mediterranean) (Odonata). *Bulletin of the entomological society of Malta* 6: 5-127. (in English) ["Seventeen species of odonates have been recorded on the Maltese Islands of which *Pantala flavescens* represents a new record. Diagnostic features of the adult and larval stages of these species are described in this work. The work also combines findings from previous literature on Maltese Odonata with information gathered from fieldwork data in order to give an insight on the current situation of the Odonata of the Maltese Islands and serves as an identification guide to both adults and larvae of these insects. The anatomy and physiology of the larval and adult forms of these insects, which are discussed in this work, are adapted to the predatory lifestyle which they lead. The fact that odonate larvae frequent different habitats from adults helps to reduce competition for resources. Adult odonates can be found in a number of local habitats, mostly near freshwater but also brackish water bodies since freshwater is a scarce natural resource on the Maltese Islands. Global warming is affecting the distribution range of odonates in the Mediterranean - while some species may be on the decline, others which can thrive in hot dry environments are progressively being recorded in the Mediterranean and southern Europe, including the Maltese Islands. Relatively little work on the Odonata of the Maltese Islands has been done previous to the present work. Most of this involves listing of locally recorded species; very little research investigates odonate behaviour and distribution. No information exists as to why species such as *Sympetrum striolatum*, and *Orthetrum cancellatum* have become progressively uncommon in recent years, and therefore more research is required on the matter. Because of limiting water resources, freshwater habitats on the Maltese Islands are quickly drained of water, which may be used for agricultural purposes. This may tend to reduce species richness of local odonates. Biologists are now considering dragonflies as biological indicators of a healthy environment and make recommendations in order to preserve the habitats frequented by these insects." 14400. Dorrington, G.E. (2013): On flying insect size and Phanerozoic atmospheric oxygen. *Proceedings of the National Academy of Sciences* 109(50): E3393-E3393. (in English) ["In a recent article in PNAS, Clapham & Karr (Clapham ME, Karr JA (2012) Environmental and biotic controls on the evolutionary history of insect body size. *Proc Natl Acad Sci USA* 109(27):10927-10930) related the maximum wing length (MWL) of different Odonoptera and Orthoptera species to Phanerozoic atmospheric oxygen partial pressure (pO_2) as predicted by the GEOCARBSULF model (2). They argued that the MWL data assigned to 10-Myr periods is well correlated with elevated Paleozoic pO_2 levels, but that the correlation weakens and is ultimately decoupled during the Mesozoic and Cenozoic. To explain the correlation, they assumed that maximum insect size is constrained by a tracheal oxygen supply limit. To explain the decoupling, they referred to the notion that insect size increase results in reduction of flight maneuverability and increased aerial predation by birds (among others), i.e., a selective pressure against size increase also operates. This convenient mixed hypothesis deserves scrutiny. ... Third, in the absence of aerial predation, the emergence of the gigantic Meganisoptera during the Carboniferous and Permian does not necessarily require elevated pO_2 levels when it is assumed that these ancient Odonoptera were weak fliers with relatively low specific maximum power outputs compared with extant Anisoptera (Odonata). Fourth, extant Anisoptera are capable of lifting loads exceeding their own weight during hover (4), indicating substantial power reserves. Large extant aeshnids have also been recorded flying at more than 2,500 m altitude above sea level (5). Therefore, at low altitude, extant Anisoptera must have wide oxygen supply margins when operating in their usual aerobic flight modes. Following Clapham & Karr, the hypothetical removal of aerial predation would result in evolving size increase. However, at the present pO_2 level, scale-up by one order of magnitude would be permissible before the tracheal surface area constrains maximum feasible size. Fifth, there is no evidence that the evasive maneuver capability of extant Anisoptera reduces as body size increases. Territorial dogfights among conspecific males tend to select larger individuals with good maneuverability and higher maximum flight speeds. Finally, the MWL history presented (Clapham & Karr) is reproduced in Fig. 1 with an important difference: two anisopteran species, *Petalura ingentissima* and *Tetracanthagyna plagiata*, have been included. There is no evidence that these large extant species evolved during any relaxation of aerial predation over the past 10 Myr. A more credible proposition is that the fossil record represented in Fig. 1 is incomplete.

The correlation reported by Clapham & Karr would then be premature." (Author)] Address: Dorrington, G.E., School of Aerospace, Mechanical and Manufacturing Engineering, RMIT University, Bundoora, VIC 3083, Australia. E-mail: graham.dorrington@rmit.edu.au

14401. Edia, E.O.; Bony, K.Y.; Konan, K.F.; Ouattara, A.; Gourène, G. (2013): Distribution of aquatic insects among four costal river habitats (Côte d'Ivoire, West-Africa). *Bulletin of Environment, Pharmacology and Life Sciences* 2(8): 68-77. (in English) ["We analysed aquatic insect distribution among four coastal river habitats of southeast Ivory Coast. In each river, two sites were sampled: one upstream and one downstream. In the eight sites, aquatic insects were randomly sampled eight times (i.e. four during the rainy season and four during the dry season) between July 2003 and March 2005. The basic criteria for classifying sampling sites by both the Principal Component Analysis and the hierarchical cluster analysis are mainly the nature of the waterbed substrate and the mineralization of the water. Overall, 115 taxa belonging to 51 families and ten orders were recorded. The richest taxon diversity was observed for Diptera and Ephemeroptera. The Indval method revealed that the most mineralized sites were characterised mostly by dipterans. However, the indicator taxa of weakly mineralized sites are mainly ephemeropterans. Taxa such as *Laccophilus* sp., *Ablabesmyia* sp., *Ceratopogon* sp., *Cryptochironomus* sp., *Labioabaetis gambiae*, *Procloeon sylvicola* and *Nanocladius* sp. were generalist in respect to the substrate nature. *Riolus* sp. *Perla* sp., *Choroterpes* sp., *Cloeon* sp. and *Ephoron* sp. were specialists of sandy substrate. *Compsoneria njalensis* was characteristic habitats whose bottom is muddy." (Authors) The checklist includes 15 Odonata species, among them *Phaon iridipennis*, *Lestinogomphus angustus* and *Phyllogomphus aethiops*.] Address: Edia O Edia, Lab. d'Environnement et de Biologie Aquatique, U.F.R.-S.G.E., Univ. 14405. Henn, M.J. (2013): Effects of artificial light on the drift on macroinvertebrates in urban central Texas streams. M.S. thesis. Texas State University San Marcos, Dept. of Biology: 28 pp. (in English) ["Since the majority of organisms operate on a circadian rhythm, light pollution in urban areas can possibly influence the aquatic community by affecting the drift of macroinvertebrates. The objective of this study is to examine if artificial night lights reduce drifting macroinvertebrates in the Edwards Plateau, by quantifying macroinvertebrate drift under ambient night light conditions and under extreme artificial lighting. This study was conducted in five streams (two large streams and three smaller streams) within urbanized areas of Central Texas.

Drifting macroinvertebrates were sampled using drift nets under two treatments: ambient lighting (control) and extreme artificial lighting. Among all streams, both taxon diversity and richness of drifting insects was similar between treatments, but average abundance of drifting insects was 37% less in artificial lighting treatment than under the control treatment. Treatment effects were more evident in larger streams than smaller streams. Average abundance of drifting insects was 40% less in artificial lighting treatment with larger streams with notable decreases in Simuliidae (58% less than the control), Baetidae (51% less), and Coenagrionidae (50% less). Reduced drift by artificial light conditions found in this study suggests the potential of artificial lighting disrupting dynamics of macroinvertebrate drift. Results of this experiment support a growing body of knowledge on how urbanized systems will influence stream communities and provide evidence to support various management strategies to minimize the effects of artificial lights on aquatic communities." (Author)] Address: Henn, Monika, Dept of Biology/Aquatic Station, Texas State University, San Marcos, TX, USA

(2013): Molecular organization of the nanoscale surface structures of the dragonfly *Hemianax papuensis* wing epicuticle. PLoS ONE 8(7): e67893. doi:10.1371/journal.pone.0067893: 8 pp. (in English) ["The molecular organization of the epicuticle (the outermost layer) of insect wings is vital in the formation of the nanoscale surface patterns that are responsible for bestowing remarkable functional properties. Using a combination of spectroscopic and chromatographic techniques, including Synchrotron-sourced Fourier-transform infrared microspectroscopy (FTIR), x-ray photoelectron spectroscopy (XPS) depth profiling and gas chromatography-mass spectrometry (GCMS), we have identified the chemical components that constitute the nanoscale structures on the surface of the wings of *H. papuensis*. The major components were identified to be fatty acids, predominantly hexadecanoic acid and octadecanoic acid, and n-alkanes with even numbered carbon chains ranging from C14 to C30. The data obtained from XPS depth profiling, in conjunction with that obtained from GCMS analyses, enabled the location of particular classes of compounds to different regions within the epicuticle. Hexadecanoic acid was found to be a major component of the outer region of the epicuticle, which forms the surface nanostructures, and was also detected in deeper layers along with octadecanoic acid. Aliphatic compounds were detected throughout the epicuticle, and these appeared to form a third discrete layer that was separate from both the inner and outer epicuticles, which has never previously been reported." 14407. Janssens, L.; Stoks, R. (2013): Fitness effects of Chlorpyrifos in the damselfly *Enallagma cyathigerum*

strongly depend upon temperature and food level and can bridge metamorphosis. PLoS ONE 8(6): e68107. doi:10.1371/journal.pone.0068107: 7 pp. (in English) ["Interactions between pollutants and suboptimal environmental conditions can have severe consequences for the toxicity of pollutants, yet are still poorly understood. To identify patterns across environmental conditions and across fitness-related variables we exposed *Enallagma cyathigerum* damselfly larvae to the pesticide chlorpyrifos at two food levels or at two temperatures and quantified four fitness-related variables (larval survival, development time, mass at emergence and adult cold resistance). Food level and temperature did not affect survival in the absence of the pesticide, yet the pesticide reduced survival only at the high temperature. Animals reacted to the pesticide by accelerating their development but only at the high food level and at the low temperature; at the low food level, however, pesticide exposure resulted in a slower development. Chlorpyrifos exposure resulted in smaller adults except in animals reared at the high food level. Animals reared at the low food level and at the low temperature had a higher cold resistance which was not affected by the pesticide. In summary our study highlight that combined effects of exposure to chlorpyrifos and the two environmental conditions (i) were mostly interactive and sometimes even reversed in comparison with the effect of the environmental condition in isolation, (ii) strongly differed depending on the fitness-related variable under study, (iii) were not always predictable based on the effect of the environmental condition in isolation, and (iv) bridged metamorphosis depending on which environmental condition was combined with the pesticide thereby potentially carrying over from aquatic to terrestrial ecosystems. These findings are relevant when extrapolating results of laboratory tests done under ideal environmental conditions to natural communities." 14408. Jara, F.G.; Úbeda, C.A.; Perotti, M.G (2013): Predatory insects in lentic freshwater habitats from northwest Patagonia: richness and phenology. Journal of Natural History, 47(43-44): 2749-2768. (in English) ["The main purpose of this work was to study the richness, phenology and abundance of predatory insects throughout the hydroperiod and how they relate to the environmental parameters in lentic bodies of water in northwest Patagonia. Nineteen fishless wetlands and three wetlands with fish were studied, which are located in the surroundings of the Nahuel Huapi National Park. Biotic and abiotic variables were measured during the hydroperiod of each wetland. The dip-netting sampling technique was used to determine the richness of predatory insects and to study the phenology of the dominant species in four wetlands. Species richness in temporary wetlands ranged from one to nine species per wetland and does not differ from that observed in the permanent environments with or without fish predators. Maximum insect richness was recorded in late spring

and was associated with the maximum depth of the wetland and its structural complexity as well as with the duration of the hydroperiod." 14409. Kastner, F.; Buchwald, R. (2013): Zum Vorkommen der FFH-Libellenarten *Coenagrion mercuriale* Charpentier, 1840 und *Coenagrion ornatum* Selys 1850 (Odonata: Coenagrionidae) im Kreis Minden-Lübbecke (Nordrhein-Westfalen). *Drosera* 2011(2013): 111-118. (in German, with English summary) ["On the occurrence of the dragonfly *Coenagrion mercuriale* Charpentier, 1840 and *Coenagrion ornatum* Selys 1850 (Odonata: Coenagrionidae), species of the European Habitat Directive, in the county Minden-Lübbecke (North Rhine-Westphalia). – *C. mercuriale* predominantly occurs in the river plains of Ems, Lippe, Hunte, and Weser in North Rhine-Westphalia. *C. ornatum* was only found in the river plains of Hunte and Weser in the county Minden-Lübbecke in North Rhine-Westphalia. The *C. mercuriale* and *C. ornatum* occur in sunny and warm, permanently flowing ditches with rich aquatic vegetation, usually with *Berula erecta*. For this study we accounted in 2011 the distribution of these two rare and endangered species in the county Minden-Lübbecke (NRW). We consider the presence of *C. mercuriale* in the three ditch systems Tiefenriede, Ilwede with Barlage and Mehner Bruch and of *C. ornatum* in the ditch systems Ilwede with Barlage and Mehner Bruch as autochthonous. *C. mercuriale* was mapped in 38 ditch sections with more than 1400 individuals and *C. ornatum* in seven ditch sections with eleven individuals." 14410. Khelifa, R.; Zebba, R.; Amari, H.; Mellal, M.K. (2013): Does wind affect emergence site selection in Odonata? *African Entomology* 21(2): 383-387. (in English) ["This study at *Erythromma lindenii* was undertaken in a 0.4 ha pond at 3 km northwest from El Fedjoudj province, Guelma, Algeria (36°31'54.30"N 7°22'48.08"E). There was a significant difference in exuvia height between males and females but no differences between sexes were noted in either their choice of support height or the density of the vegetation in which they emerged. Females climbed higher than males probably because females had significantly larger head width. This differential vertical stratification of exuviae between sexes has not been investigated in previous studies. However, it might also be related to differential maiden flight between sexes, i.e. females might climb higher to take a longer flight while males climb lower heights and fly shorter distance. This assumption requires an independent study that takes into account both the exuvia height and maiden flight distance

for each sex. Exuvia height, for both sexes, was highly positively correlated with support height. Mean and maximum wind speed were significantly negatively correlated to exuvia height and support height. However, mean and maximum wind speed were positively related to vegetation density where exuviae were found. That is, when wind speed was high larvae tended to choose lower heights, lower supports, and highly vegetated areas in order to emerge successfully without any damage. Another alternative explanation is that wind might not have behavioural effects in habitat choice but at higher wind speed the exuviae get blown off the plants if they are higher. Indeed, low vegetated sites and upper parts of emergent plants were subject to higher turbulences in windy conditions. In addition, mean and maximum wind speed were not significantly correlated to daily emerging population size. Neither the mean height of exuviae above water nor the mean height of the chosen support were significantly correlated with the daily emerging population size." 14411. Kis, O.; Vajda, C.S.; Gyulavári, H.A.; Szabó, L.J.; Miskolczi, M., Devai, G. (2013): Morphological characterisation of an adult population of Eastern Willow Spreading (*Chalcolestes parvidens*, Artobolevsky, 1929) from NE-Hungary. *Studia odonotol. hung.* 15: 49-72. (in Hungarian, with English summary) ["The taxonomical status of *C. parvidens* is widely controversial in Europe. The taxa *C. parvidens* were described as a subspecies of *Chalcolestes viridis*. Recently some authors consider it as a species by the results of phenotypic features and electrophoretic analysis. We found very few information on the taxa *C. parvidens*, so our aim was to provide a comprehensive morphometric characterization of the taxa based on a NE-Hungarian adult population. In this study we measured body, thorax side and wing traits. The data were processed by descriptive statistics and multivariate analysis. In case of selected traits we examined the correlation between them by linear regression analyses. Our results showed that males had significantly larger body than females. Females nevertheless had significantly wider head and longer wings. The multivariate analysis divided the sexes clearly based on the body and wing measurements. However in case of the thorax side measurements the sexes could not be separated clearly." 14415. Marinov, M. (2013): Contribution to the Odonata the Kingdom of Tonga. *Faunistic Studies in South-East Asian and Pacific Island Odonata* 1: 1-18. (in English) ["New data on the Odonata fauna of the Kingdom of Tonga is provided following research carried out on Tongatapu and 'Eua islands in July 2012. New localities for Tongatapu Island are put on record and previous studies are compared with new phenological data from a period during

which field surveys are rarely conducted on Pacific islands. Although Odonata have been collected before from 'Eua Island, the data presented here is the first published so far. 'Eua Island is assessed as a very important venue for further research on Odonata. Overall the Kingdom of Tonga is very depauperate in water resources with lotic biotopes very restricted in area and found on 'Eua Island, and possibly on Tofua and Late islands, which are both volcanic. This study on the Odonata of 'Eua resulted in records of eight taxa, including with *Teinobasis* sp. nov., which will be described elsewhere. Morphological variation in *Pseudagrion microcephalum stainbergerorum* and *Tramea transmarina* are discussed in the context of their subspecific affiliation. Diagnostic features for easier differentiation are proposed for the first of these taxa; the validation of commonly used diagnostic traits is discussed for the second." 14416. Ottonello, D.; Oneto, F. (2013): Libellule di Liguria (Odonata). *Annali del Museo Civico di Storia Naturale "G. Doria"* 105: 297-425. (in Italian, with English summary) ["Dragonflies from Liguria (Odonata). This paper updates the knowledge about dragonflies observed within the administrative boundaries of Liguria (North-west of Italy) to nearly seventy years since the last paper at regional scale (Capra 1945). The study was carried out through the collection of new data and through a revision of bibliography and museological collections. A geographic database was compiled with approximately 3,000 records, representing a relevant sampling effort with about one record every two square kilometers. Of these, 500 are published and 2,500 are unpublished data, the latter mainly collected in the last seven years (88%). A total of 57 species, 23 Zygoptera and 34 Anisoptera, are recorded for the study area, representing the 61% of the Italian odonotofauna. Four species are recorded as new for Liguria: *Coenagrion pulchellum*, *Ophiogomphus cecilia*, *Libellula fulva* and *Trithemis annulata*. Conversely, five historically-recorded species were not found during the last years: *Coenagrion mercuriale*, *Erythromma najas*, *Sympetrum vulgatum*, *Somatochlora flavomaculata* and *S. meridionalis*. The Ligurian odonotofauna is mainly composed by Palearctic species (84%), followed by Holarctic (7%), Afro-european (5%) and Afro-tropical (4%) species. Specimens were observed in flight from the sea level up to 1700 m a.s.l., with a higher number of species present at elevation of up to 1000 m, and only six species reaching the highest altitude. The flight season is mainly concentrated in the summer with the following number of species observed for each month: January (0), February (1), March (0), April (7), May (25), June (43), July (47), August (45), September (27), October (10), November (4), December (0). The most important areas, for biogeographical reasons or for highest number of species, are located in the "Genoese Apennine" (Aveto valley,

Roccagrande and Orba valley), in the Po valley encompassing the provinces of Genoa and Savona (Stura valley and Erro valley), in the Bormida valley and in the western area (River Centa basin, high Tanaro valley and Roja valley)." 14418. Rivers-Moore, N.A.; Fowles, B.; Karssing, R.J. (2013): Impacts of trout on aquatic macroinvertebrates in three Drakensberg rivers in KwaZulu-Natal, South Africa. *African Journal of Aquatic Science* 38(1): 93-99. (in English) ["Global literature suggests that trout, when introduced as alien species into local streams, have had deleterious impacts on aquatic community structure and function. Prior to defining management actions regarding trout in the rivers of the Ukhahlamba-Drakensberg Park (UDP), data are required on their impacts on local aquatic communities. In February 2007, aquatic macroinvertebrate communities were sampled at three locations in streams in the UDP. Paired sites were separated by waterfalls, with no trout occurring upstream but occurring at low densities downstream. Differences in aquatic macroinvertebrate communities between upstream and downstream sites were apparent but, within the constraints of this study, such differences could not be directly attributed to trout predation. Further studies are recommended in order to provide additional information on seasonal variation in these patterns, as well as on density-dependent effects of trout on aquatic macroinvertebrate communities." 14420. Sanderson, H.; Compennolle, R. van; Dyer, S.D.; Price, B.B.; Nielsen, A.M.; Selby, M.; Ferrer, D.; Stanton, K. (2013): Occurrence and risk screening of alcohol ethoxylate surfactants in three U.S. river sediments associated with wastewater treatment plants. *Science of the Total Environment* 463–464: 600-610. (in English) ["Alcohol ethoxylates (AE) are high production volume (HPV) chemicals globally used in detergent and personal care products and are truly a work-horse for the household and personal care industries. Commercial AE generally consist of a mixture of several homologues of varying carbon chain length and degree of ethoxylation. Homologues that are not ethoxylated are also known as aliphatic alcohols or simply fatty alcohols (FA). This group of homologues represents a special interest in the context of environmental risk, as these are also abundant and ubiquitous naturally occurring compounds (e.g. animal fats and in human feces). Hence, in a risk assessment one needs to distinguish between the natural (background) concentrations and the added contribution from anthropogenic activities. We conducted a weight-of-evidence risk assessment in three streams, documenting the exposure and predicted risk, and compared these to the habitat and in situ biota. We found that the parameters (e.g., habitat quality and total perturbations hereunder total suspended solids (TSS) and other abiotic and biotic stressors) contributed to the abundance of biota rather than the predicted risk from AE and FA. Moreover, the documented natural *de novo* synthesis and rapid degradation of FA highlight the need to carefully consider the procedures for environmental risk assessment of naturally occurring compounds such as FA, e.g. in line with the added risk concept known from metal risk assessment. ... At the species level, twelve species were found only upstream, with a total abundance of 71 animals from all three locations. Of these 71 animals across all streams, only one species, *Boyeria vinosa* ... were found only to be present upstream in more than one stream. In the Bryan upstream location, twenty six *B. vinosa* were identified and one *B. vinosa* was identified in the Wilmington upstream location, suggesting that this was the most sensitive species overall on a qualitative basis." 14430. Wujek, D.E. (2013): Epizootic diatoms on the cerci of Ephemeroptera (Caenidae) naiads. *The Great Lakes Entomologist* 46(1-2): 116-119. (in English) ["Using scanning electron microscopy, epizootic diatoms were observed growing on the cerci of *Caenis amica* Hagen naiads (Ephemeroptera, Caenidae). *Meridion circulare* (Greville) C. Agardh was the most abundant, followed by *Synedra rumpens* Kützing, then *Cocconeis pediculus* Ehrenberg. Other diatom species observed from substrates in Cedar Creek, Isabella Co., Michigan were not observed on the cerci. No diatoms were observed on Ephemeroptera naiads. Epizootic algae are not infrequent on the surfaces of most active animals. The association between slugs and epizootic algae was one of the first to be described showing this unusual and interesting association since such relationships were described (Kuhn in Welcher 1864). Freshwater epizootic algae have been described from a variety of hosts. These include protists (Wiley et al. 1970, Pérez-Martinez et al. 2001); invertebrate animals such as Cladocera (Gaiser and Bachmann 1993, Barea-Arco et al. 2001), Rotifera (Wujek 2006); insects including Trichoptera (Bergey and Resh 1994, Sheath et al. 1995), Diptera (Sheath et al. 1996), and Odonata (Wujek pers. observ.); Crustacea together with Copepods (Russell and Norris 1971) and crayfish (Fuelling et al. 2010)."] (Author)] Address: Wujek, D.E., Dept Biol., Central Michigan Univ., Mt. Pleasant, MI 48859, USA. E-mail: wujek1de@cmich.edu

(2013): Patterns of density dependence in growth, reproduction and survival in the invasive freshwater snail *Pomacea canaliculata* in Japanese rice fields. *Freshwater Biology* 58(10): 2065-2073. (in English) ["Patterns of density dependence in growth, reproduction and survival are important for predicting the population dynamics of a species. The patterns may change with environmental factors, such as the harshness of winter, but very little is known about such patterns and their mechanisms in unmanipulated natural populations of invasive animal species. We studied the extent of density dependence in the growth, reproduction and survival of an invasive freshwater snail, *Pomacea canaliculata*, in rice fields in Nara (cold district) and Kumamoto (warm district), Japan, over 2- and 1-year periods, respectively. In both areas, growth was negatively density dependent within the same generation, and the density of snails in the parental generation negatively affected the growth of offspring. The number of eggs per unit area was independent of adult density, suggesting eggs per adult female were few at high densities. Survival over the cold winter of 2005–2006 was independent of density in Nara. However, survival over the warm winter of 2006–2007 in both Nara and Kumamoto was negatively density dependent. Irrespective of the various negative density-dependent patterns, population density tended to show positive correlations with the density of the previous generation. This appears to reflect the substantial capacity of this snail to resist extremely low densities due to the various negative density-dependent patterns rather than indicating susceptibility to extinction at low densities... Few predators of the apple snail are found in Japanese rice fields (Yusa, Sugiura & Wada, 2006; Yamanishi et al., 2012), and we rarely observed predators of the snail in our study fields, with the exception of some dragonfly larvae (mainly *Pantala flavescens*) after the mid-term .."] (Authors)] Address: Yusa, Yoichi, Faculty of Science, Nara Women's University, Kitaouya-nishi, Nara 630-8506, Japan. 14434. Abelova, M.; David, S. (2014): Morphometry of *Aeshna cyanea* (Müller, 1764) (Odonata: Aeshnidae) exuviae from the territory of Slovakia. *Entomofauna carpathica* 26(1): 1-11. (in Slovakian, with English summary) ["The study elaborates the morphometric analysis of 87 exuviae specimens of *A. cyanea* from 6 localities of Slovakia. Measured and statistically evaluated are 6 morphometric signs for exuviae of *A. cyanea*. We confirmed several distortions of normality of data, partly caused by measurement error. The exuviae of females are larger in measured signs except the length of the thigh (femura) than males. It has been proved that the dependence of signs is often not linearly correlated. The results are also important, because morphometric signs are used in the designation keys and in the research of development stages of larvae and exuviae. We have processed so far the largest data set of morphometric data for Slovakia." (Authors)] Address: Ábelová, Monika, Dept Ecol. & Environ. Sci., Fac. Nat. Sci., Constantine the Philosopher Univ. in Nitra, Tr. A. Hlinku 1, 949 74 Nitra, Slovak Republic. E-mail: monika.abelova@ukf.sk

14436. Altamiranda-Saavedra, M.; Palacino-Rodríguez, F.; Lobo-Hernández, M. (2014): Daily abundance at the breeding site and reproductive behavior of *Polythore gigantea* (Odonata: Polythoridae). *Odonatologica* 43(3/4): 169-182. (in English) ["Daily abundance at the breeding site and reproductive behavior of *P. gigantea* are described in different localities of Antioquia, Colombia. Observations were done between March and June 2009 from 08:00 to 16:00 h. The highest reproductive activity (i.e. maximal abundance of individuals at the breeding site) was observed between 11:06 and 12:12 h. Oviposition lasted 10 min on average. During courtship, the male exhibited rhythmical movements by opening and closing the wings rapidly, getting closer to the female and holding her in tandem. During oviposition, the female inserts the eggs inside wet trunks and little twigs in the surrounding vegetation under the close surveillance of the male. Males exhibit territorial behavior and conspecific aggression to defend the territory. Factors such as vegetation cover, might influence the time of the day in which oviposition occurs. This study provides, for the first time, information on the reproductive behavior of *P. gigantea*." (Authors)] Address: Altamiranda-Saavedra, M., Grupo Microbiología Molecular, Univ. de Antioquia, Apdo. Postal 1226, Calle 67 No. 53-108, off. 5-430, Medellín, Colombia. 14437. Amri, N.; Jamili, S.; Abdolbaghian, S. (2014): Diversity of macrobenthos communities and their relationships with environmental factors in Jajroud River, Iran. *Resources and Environment* 4(2): 95-103. (in English) ["This paper evaluates the diversity of common groups of macrobenthos include: Diptera, Ephemeroptera, Odonata, Plecoptera, and Gastropoda and their relationships with environmental variables in the Jajroud river northeast of Tehran province (capital of Iran). The work has been extended out over a period of 12 months through three stations. Macrobenthos sampling has been carried out monthly with three replications in each station. Water temperature, dissolved oxygen, pH, BOD, phosphate and nitrate concentrations were within ranges usually capable of backing up a diverse biota. The other components such as water depth, water width, water flow and contamination were as well taken. The methodologies applied by a number of research groups were generally similar, making it possible to compare outcomes between different areas. Three metrics were utilized to show the diversity: Margalef richness, Shannon-Weaver's diversity index (.) and evenness index (E). From 108 Surber samples, 29 families, 39 genus and 92 species were identified (42% Ephemeroptera, 38% Diptera, 18% Plecoptera, 1.2% Gastropoda and 0.8% Odonata (*Argia adamsi*; *Aeshna affinis* [sic]) of the total fauna population). Chironomidae, Baetidae and Perlodidae were the most dominant families. The biodiversity of the community of the upper reaches of the river (ST1) was the highest that of the lower reaches (ST2) was the lowest that of (ST3) ranked in the middle. In this work, the presence of pollution-tolerant families in (ST3) indicates that this site is ecologically unhealthy. The diversity of Gastropoda and Chironomidae were significantly affected by pollution (positively) and water depth; whereas the diversity of Ephemeroptera by the dissolved oxygen and water temperature respectively. Besides the diversity of Odonata was affected by stream width. The outcome of a One-Way ANOVA for three metrics indicates the P - value and F-critical 3.1 and 5.1 respectively." (Authors)] Address: Amri, Niusha, Science & Research Branch of Islamic Azad Univ., Tehran, Iran. E-mail: niushaamri@gmail.com

14438. Andersen, E. (2014): *Aeshna viridis* distribution and habitat choices in South and Central Sweden and the possibility to use a database as a tool in monitoring a threatened species. B.Sc. thesis, Halmstad University, School of Business and Engineering (SET), Biological and Environmental Systems (BLESS), Ecology and Environmental Science: 15 pp-["*Aeshna viridis*, a dragonfly generally considered to be a specialist as it in most cases chooses *Stratiotes aloides* as its habitat, have suffered badly from habitat loss and fragmentations throughout Europe under the last century as the human demand of land use have grown. It's thereby considered near threatened on EU red list and is included in the Habitat Directive. This means that it is protected by EU law as all EU Member States is committed to protect, monitor and report back to EU the status of the species. Several European countries

have designed protection plans for *S. aloides* to improve the preservation of *A. viridis*. My study in South and Central Sweden shows that the strong connection between *A. viridis* and *S. aloides* may not be consistent all over the distribution range of *A. viridis*, as my survey showed that larvae occur among other water plants when *S. aloides* is not present. Another aim in this study was to evaluate the possibility to use occurrence data on *A. viridis* and *S. aloides* from the Species Observations System to monitor *A. viridis* distribution and dispersal. My study implies uncertainties of how well the datasets reflects reality and more research is necessary before clarifying if datasets could be a possible tool in conservation management of *A. viridis*." (Author)] Address: Andersen, Emelie, Halmstad University, School of Business and Engineering (SET), Biological and Environmental Systems (BLESS), Ecology and Environmental Science), Sweden

14439. Ayme-Southgate, A.; Crowe, M.; Southgate, R. (2014): The NH2-terminal Ig domains of insect projectin could serve as elastic elements. *Proteomics and Genomics Research* 1(1): 21-33. (in English) ["The connecting C-filaments of insect indirect flight muscles have been proposed as one of the elements providing muscle elasticity for the asynchronous muscle physiology of derived insects. Two large modular proteins, kettin/Sallimus and projectin make up these filaments, and for both proteins the N-terminal sequences span the extensible I-band and are proposed as the elastic segments. The C-filaments have not been studied in insects, such as dragonflies (*Pachydiplax longipennis*), crickets, and Lepidoptera with muscles which are largely synchronous in physiology and display different levels of muscle stiffness. In this paper we focus our efforts on the projectin protein of several insects with synchronous flight muscles; namely dragonfly, cricket, and moth. We provide evidence for the localization of projectin over the sarcomere I-Z-I region that is consistent with the existence of C-filaments in synchronous flight muscles. Additionally, we determine the sequences for the NH2-terminal region of projectin in these insects and describe the presence of alternative splice variants. Using predictors of intrinsically disordered regions, we identify possible unfolded segments, especially around the short linker sequences found between the NH2 Ig domains. We propose a possible picture of projectin NH2-terminal region organized as different segments contributing elastic responses to stretch by either unfolding of highly disordered sequences (PEVK) or reorientation of domains by bending or twisting of disordered linkers between the Ig domains." 14440. Babu, R.; Nandy, S. (2014): Eight new records of dragonflies from Jharkhand State, India (Odonata: Aeshnidae, Gomphidae, Libellulidae). *Notulae odonatologicae* 8(4): 91-93. (in English) ["A field survey carried out in 2008–2010 and examination of the collection of the National Zoological Collection, Zoological Survey of India (ZSI),

Kolkata recorded eight Anisoptera species new for the state of Jharkhand. These are *Anaciaeschna jaspidea*, *Gynacantha dravida*, *Hemianax ephippiger*, *Orthetrum glaucum*, *O. luzonicum*., *Tramea limbata similata*, *T. virginia*, and a yet unidentified species of *Anisogomphus* Selys, 1858. These records increase the number of odonate taxa known from Jharkhand State to 73." (Authors)] Address: Babu, R. Southern Regional Centre, ZSI, Chennai-600 028, India. E-mail: baburzi@gmail.com

14441. Baird, R.C. (2014): Larval burrow morphology and groundwater dependence in a mire-dwelling dragonfly, *Petalura gigantea* (Odonata: Petaluridae). *International Journal of Odonatology* 17(2/3): 101-121. (in English) ["Most species of petalurid dragonflies have a fossorial larval stage, which is unique in the Odonata. Larvae typically excavate burrows in soft peaty soils in mires, seepages or along stream margins, which are occupied by a single larva throughout the long larval stage. This paper reports on a study of burrow morphology in *Petalura gigantea*, with the objectives of describing their burrows, documenting any variability in burrow morphology across the hydrogeomorphic range of habitats used by the species, identifying factors contributing to any such variability, resolving questions in relation to the single previous illustration of a burrow system and identifying the level of groundwater dependence of larvae. The species was found to be an obligate, groundwater dependent, mire-dwelling species with well-maintained and sometimes complex burrows. Burrow complexity and morphological variation are inferred to be a response by larvae to the hydrogeomorphic characteristics of the habitat and substrate attributes. All burrows were occupied by a single larva, consistent with previous observations of other fossorial petalurids, but in contrast to the previous description of a *P. gigantea* burrow complex occupied by multiple larvae. The functional role of identified burrow features is discussed. Although the fossorial larval habit confers ecological benefits, the species' groundwater dependence and restriction to mire habitats places it at increased risk in the event of any reduction in groundwater availability, more intense fire regimes, and the potential compounding effects of rapid climate change." (Author)] Address: Baird, R.C., College of Health and Science, University of Western Sydney, Penrith South DC, NSW 1797, Australia

14442. Baird, R.C. (2014): Mate guarding and other aspects of reproductive behaviour in *Petalura gigantea* (Odonata: Petaluridae). *International Journal of Odonatology* 17(4): 223-236. (in English) ["Territorial behaviour and mate guarding are important components of mating systems in various insect groups, including the Odonata. This paper reports observations of male territorial behaviour associated with potential ovipositing sites, and postcopulatory, non-contact mate guarding in *Petalura gigantea*. This is the first unambiguous and detailed report of mate guarding in the Petaluridae. Additional observations of previously undocumented aspects of reproductive behaviour are also reported. These observations are compared

with other petalurids." (Authors)] Address: Baird, R.C., College of Health and Science, University of Western Sydney, Penrith South DC, NSW 1797, Australia

14443. Ball-Damerow, J.E.; M'Gonigle, L.K.; Resh, V.H. (2014): Local and regional factors influencing assemblages of dragonflies and damselflies (Odonata) in California and Nevada. *Journal of Insect Conservation* 18: 1027-1036. (in English) ["Studies of landscape effects on assemblages and distribution of insects are relatively uncommon, largely because of the lack of occurrence data that span broad spatial or temporal scales. Here, we provide a multi-species analysis using generalized linear mixed models to examine the effects of local and regional variables on richness and occurrence rates of Odonata species at 81 sites throughout central California and north-western Nevada, USA. These study sites were located across a range of ecoregions, including the Sierra Nevada Forests, California Mediterranean, Great Basin Shrub Steppe, and Northern Coastal California Forests. Dynamic regional variables in this study, degree-days and precipitation, influenced the richness of dragonflies, but not the less-mobile damselflies. In contrast, local habitat type influenced the richness of damselflies, but not dragonflies. Overall species occurrence was higher during site visits with higher degree-days, especially for highly mobile groups including dragonflies and migratory species. Dragonflies were also positively associated with total precipitation, but migratory species were not. Probability of presence across species was lower in highly urban sites, particularly for habitat specialists. Further, habitat specialists had lower rates of occurrence overall, suggesting that widespread generalist species may increasingly dominate Odonata assemblages. Our study indicates that Odonata in this semi-arid region are responsive to a combination of local and regional environmental variables." (Authors)] Address: Ball-Damerow, Joan, Dept of Environ. Sci., Policy & Management, Univ. of California, Berkeley, 130 Mulford Hall #3114, Berkeley, CA 94720-3114, USA. E-mail: joan-damerow@gmail.com

14444. Barry, M.J. (2014): Fluoxetine inhibits predator avoidance behavior in tadpoles. *Toxicological & Environmental Chemistry* 96(4): 641-649. (in English) ["Fluoxetine is a selective serotonin re-uptake inhibitor used to treat anxiety and depression in humans. It has been detected as a contaminant in the surface waters in many countries. The effects of fluoxetine (0, 0.03, 0.3, and 3 µg L⁻¹) on the swimming and behavioural responses of *Bufo arabicus* tadpoles to alarm chemicals from predatory dragonfly larvae (*Anax imperator*) were measured. Fluoxetine significantly reduced swimming speed at 0.3 and 3 µg L⁻¹ in the absence of predator alarm chemicals but had no effect in their presence. Tadpoles exposed to predator alarm chemicals avoided open water and preferred to hide. Exposure to fluoxetine at 3 µg L⁻¹ completely eliminated this predator avoidance response, making the tadpoles more vulnerable to predation." (Author)] Address: Barry, M.J., Biology Dep.t, Sultan Qaboos University, Muscat, Oman

14445. Bashar, K.; Reza, M.S.; Razzak, M.A.; Rahman, K.M.Z.; Goda, P.; Howlader, A.J. (2014): Faunistic study of Odonata (dragonfly & damselfly) in some selected regions of Bangladesh. *Journal of Entomology and Zoology Studies* 2(4): 1-6. (in English) ["A study was conducted to investigate the species diversity of Odonata in five selected areas of Bangladesh viz. Dhaka, Moulvibazar, Bandarban, Chuadanga and Khulna during July' 2009 to June' 2010. A total of 3350 individuals belonging to 48 species under 8 families were observed during the study period. Among them 25 species were dragonflies under the families; Libellulidae (22), Aeshnidae (2) and Gomphidae (1), whereas the remaining 23 species were damselflies under five families; Coenagrionidae (16), Platycnemididae (4), Calopterygidae (1), Lestidae (1), Protoneuridae (1). The highest and lowest number of species was observed in Dhaka (31) and Bandarban (23), respectively. Libellulidae was the dominant family whereas few species were found under the family Gomphidae, Lestidae, Calopterygidae and Protoneuridae. Species composition was highest in the family Libellulidae (45.8%) followed by the family Coenagrionidae (33.3%). Post-monsoon represented by 45 species was the optimum season for Odonata. The present surveillance yielded one new species of Dragonfly, *Gynacantha dravida* and five Damselfly species: *Aciagrion pallidum*, *Ceriagrion praetermissum*, *Lestes elatus*, *Copea chantaburii* and *C. ciliata* in the perspective of Bangladesh. The above results indicate that study of Odonate species in other regions of the country would provide insight in updating the checklist of Odonate species in the country, and know their ecology, and their relative importance for the successful conservation strategy and impact of climate change on this group of insects." (Authors)] Address: Bashar, K., Department of Zoology, Jahangirnagar University, Savar, Dhaka-1342, Bangladesh

14454. Brockhaus, T. (2014): Mark-recapture studies on co-occurring *Sympetma fusca* (VANDER LINDEN, 1820) and *S. paedisca* (BRAUER, 1877) (Odonata: Zygoptera: Lestidae). *Polish Journal of Entomology* 83: 225-234. (in English) ["Maturation cohorts and reproductive cohorts of the two *Sympetma* species were studied in Chomutov (Czech Republic) from 2010 to 2013. During individual mark-recapture studies, a total of 705 winter damselflies were recorded, 473 of which were individually marked (375 *S. fusca*, 98 *S. paedisca*). The recapture rates in the maturation habitat and in the reproductive habitat were low. The population estimate using CHAPMAN's method for low recapture rates could not be carried out separately for the two species owing to the low recapture rate of *S.*

paedisca. The proportion of females was greater in the maturation habitat and significantly lower than that of males in the reproductive habitat. The reproductive habitat was predominantly inhabited by territorial males. All the females observed there were engaged in reproductive activities. There was a close correlation between the male density along the shoreline and reproductive activities. *S. paedisca* was less abundant than *S. fusca*. No differences between the two species were observed in reproductive behaviour. However, *S. paedisca* appeared to disperse continuously away from the maturation habitat. Perhaps this species prefers more open areas as maturation and wintering habitats. *S. fusca* was observed here until October." 14456. Buckland-Nicks, A.; Hillier, K.N.; Avery, T.S.; O'Driscoll, N.J. (2014): Mercury bioaccumulation in dragonflies (Odonata: Anisoptera): Examination of life stages and body regions. *Environmental Toxicology and Chemistry* 33(9): 2047-2054. (in English) ["Dragonflies (Odonata: Anisoptera) are an important component of both aquatic and terrestrial food webs and are vectors for methylmercury (MeHg) biomagnification. Variations in mercury content with life stage and body regions may affect the relative transfer of mercury to aquatic or terrestrial food webs; however, there has been little research on this subject. Also, little is known about mercury bioaccumulation in different body regions of dragonflies. To address these knowledge gaps, dragonfly naiads, adults, and exuviae were collected at 2 lakes in Kejimikujik National Park, Nova Scotia, Canada, and mercury concentrations in different life stages and body regions were quantified. Mean whole body concentrations of MeHg were substantial in naiads (232 ± 112 ng g⁻¹ dry wt, n = 66), emerging adults (236 ± 50 ng g⁻¹ dry wt, n = 10), and mature adults (231 ± 74 ng g⁻¹ dry wt, n = 20). Mean MeHg concentrations in exuviae (5.6 ± 4.3 ng g⁻¹, n = 32) were 40-fold lower than in naiads and adults. Emerging adults had 2-fold to 2.5-fold higher Hg(II) concentrations than naiads, mature adults, and exuviae. In body regions of both naiads and adults, some abdomens contained significantly higher concentrations of Hg(II) than heads or thoraces, and this trend was consistent across families. Across families, Aeshnidae had significantly higher concentrations of MeHg and total Hg than Gomphidae and Libellulidae, but not higher than Corduliidae. The Hg(II) concentrations were lower in Aeshnidae and Libellulidae than in Gomphidae and Corduliidae. Shedding of exuviae presents a possible mechanism for mercury detoxification, but mercury concentrations and

burdens in exuviae are low in comparison with naiads and adults. Dragonfly adults retain a high potential for transferring substantial amounts of MeHg to their predators." 14457. Bush, A.; Hermoso, V.; Linke, S.; Nipperess, D.; Turak, E.; Hughes, L. (2014): Freshwater conservation planning under climate change: demonstrating proactive approaches for Australian Odonata. *Journal of Applied Ecology* 51(5): 1273-1281. (in English) ["(1) Climate change represents a major challenge for conservation in the future and undermines protection within reserve boundaries. Freshwater biodiversity is still under-represented within reserves world-wide, and connectivity among reserves will become increasingly crucial if species are to persist under climate change. (2) We tested the likely benefits of including predicted species distributions in systematic reserve design for rivers under climate change and the impact of varying connectivity requirements on future representation. We used the modelled distribution of 126 east Australian Odonata to identify reserve networks using data for current or future (2055 and 2085) distributions either by filling gaps additively, or as separate targets in a single solution. We then assessed the potential improvements to species representation in the future using different types of connectivity penalties that emphasized either longitudinal riverine connections or connections to all neighbouring subcatchments. (3) Solutions that did not include future distributions in the planning stages were 16 to 30% less likely to protect the same species by 2055 and 2085, respectively. Inclusion of species' future distributions in the design phase leads to short-term increases in cost, but in the longer term fewer additional areas are required to meet targets and this strategy is likely to be significantly more efficient than implementing systematic design in stages. In addition, solely targeting riverine connectivity was significantly less likely to protect current species in the future than if cross-catchment connections were included. (4) Synthesis and applications. Where protected areas can be expanded to assist species adaptation to climate change, significant gains in efficiency are possible if longer term goals are considered when selecting sites. Furthermore, to improve the representation of species under future climates, reserve selection should consider inter-catchment connectivity, although the nature of optimal solutions will depend heavily on the range of taxa included, their dispersal capacity, and the availability of climatic refugia." 14458. Bush, A.A.; Nipperess, D.A.; Theischinger, G.; Turak, E.; Hughes, L. (2014): Testing for taxonomic bias in the future diversity of Australian Odonata. *Diversity and Distributions* 20(9): 1016-1028. (in English) ["Aim: Invertebrates are often overlooked in assessments of climate change impacts. Odonata are a significant component of

freshwater macroinvertebrate diversity and are likely to be highly responsive to a changing climate. We investigate whether climate change could lead to significant alteration of continental patterns of diversity and whether vulnerable species are taxonomically clustered. Location: Australia. Methods: Habitat suitability of 270 odonate species was modelled, and a simplified phylogeny was developed based on taxonomic relationships and expert opinion. These maps were then combined to compare species richness, endemism, taxonomic diversity (TD) and taxonomic endemism (TE) under climate change scenarios, and estimate turnover in species composition. Based on the concentration of vulnerable species in regions associated with Gondwanan relicts, we tested the possibility that a focus on species loss would underestimate loss of evolutionary diversity. Results: Species richness of Australian Odonata is concentrated in the Wet Tropics, central-north Australia and south-east Queensland. Several additional regions support endemic assemblages, including the Victorian alpine region, the Pilbara and far south-western Australia. Major shifts in composition are expected across most of the east coast in response to climate change, and Tasmania has the potential to become a major refuge for mainland species. For many regions, the loss of TD is greater than expected based on the changes in species richness, and the loss of suitable habitat was unevenly distributed among families. However, the potential loss of evolutionary diversity among vulnerable species was not significantly different from random. Main conclusions: The major shifts in the distribution of Australian odonate diversity predicted to occur under climate change imply major challenges for conservation of freshwater biodiversity overall. Although major evolutionary losses may be avoided, climate change is still a serious threat to Australia's Odonata and poses an even greater threat to Australian freshwater biodiversity as a whole." 14459. Campos, F., Velasco, T.; Santos, E.; Sanz, G.; Casanueva, P. (2014): Distribución de *Coenagrion mercuriale* (Charpentier, 1840) (Odonata, Coenagrionidae) en el norte de la provincia de Valladolid, España. Boln. Asoc. esp. Ent. 38 (3-4): 279-293. (in Spanish, with English summary) ["This paper analyzes the distribution of *C. mercuriale* in the northern half of the province of Valladolid and the variation of dorsal drawing design of the second abdominal segment (S2) among males of the nearby populations. The species was detected in 61 different locations, the streams being the most numerous (86.9 % of cases), followed by rivers (4.9%), ponds (3.3%), channels (1.6%), upwellings (1.6%) and wells (1.6%). Three designs of the dorsal drawing were found, one of them in 13.7% of males and the another two in 43.7% and 42.6% of males. Since in the study area there are large populations found in small streams that dry up in summer, a better management of the flow in these natural channels as a measure of conservation of the species is suggested." 14460. Chahl, J.; Mizutani, A. (2014): Dragonfly hover is primarily mediated by vision. Proc. SPIE 9055, Bioinspiration, Biomimetics, and Bioreplication 2014, 905516 (8 March 2014); doi: 10.1117/12.2045029: 5 pp. (in English) ["The sensory means by which hover is achieved could be inertial, visual or an unexplained sensory modality. Dragonflies in their natural habitat were shown not to maintain a stationary position in wind. Their position fluctuated significantly while returning to the original position. The movement of the dragonfly is correlated with the movement of vertically standing vegetation. This response would be non-causal with wind for an inertial or putative pressure based internal sensory system. It is postulated that with a substrate of moving water, sensitivity to movement on the visual horizon for controlling hover is a robust strategy." 14461. Chand, S. (2014): Pyrethroid pesticides induced impairments in midgut histo-architecture of naiad of *Trithemis aurora* (Burm.) dragonfly (Odonata: Libellulidae). Advances in BioResearch 5(2): 130-137. (in English) ["The midgut of last instar naiad of *T. aurora* was exposed to LC50 concentrations 2.69 x 10⁻⁵ and 2.50 x 10⁻³ ppm of cypermethrin and deltamethrin pesticides respectively for 40 hrs, exhibited positive histo-pathological derangements in various midgut tissues. High accumulation of cell contents was seen at apical ends of epithelial cells. The displacement of nuclei was observed and nuclear membrane was found damaged. The circular muscles become contracted and longitudinal muscle bundles remained damaged under cypermethrin constrain. The deltamethrin reacted with epithelial folds, separating their latero-apical ends for more pesticidal activity. The intercellular boundaries of epithelial cells were perfectly damaged at the basal portion of epithelial folds. The peritrophic membrane was damaged. The circular and longitudinal muscles were affected by the pesticide." (Author)] Address: Chand, S., P G Department of Zoology, R.P.G. College Jamuhai, Jaunpur - 222 002, India

14462. Chang, Y.-H.; Ku, C.-R.; Yeh, N. (2014): Solar powered artificial floating island for landscape ecology and water quality improvement. Ecological Engineering 69: 8-16. (in English) ["This study uses solar artificial floating islands (SAFI) for water purification and biological conservation. The site of experiment is set up on a lake shore on a university campus, where the eutrophic contents of lake and sewage from the student dormitory are used for result assessment. The study demonstrates that the SAFI is able to reduce the EC of the eutrophic contents by 30% and enhance dissolved oxygen (DO) by 2.8 times. The SAFI is also able to reduce electric conductivity of dormitory sewage by 34% and increase dissolved oxygen by 982 times. After the improvement, the oxidation–reduction property is

above +100 mV and the oxidation activities in samples are vigorous. The habitation of *Ischnura senegalensis*, *Leucauge magnifica* Yaginuma, and *Duttaphrynus melanostictus* can be observed in the SAFI enhanced water area, while the area without the influence of the SAFI lacks dissolved oxygen and water plants, which results in the common Culicidae, *Hirudo nipponica* Whitman, and Chironomida in rotten water. This research shows that the SAFI has determinant influence on the ecology and water quality improvement." 14463. Chauhan, P.; Hansson, B.; Kraaijeveld, K.; de Knijff, P.; Svensson, E.I.; Wellenreuther, M. (2014): De novo transcriptome of *Ischnura elegans* provides insights into sensory biology, colour and vision genes. *BMC Genomics* 2014, 15:808 doi:10.1186/1471-2164-15-808: 14 pp. (in English) ["Background: There is growing interest in odonates as model organisms in ecology and evolutionary biology but the development of genomic resources has been slow. So far only one draft genome (*Ladona fulva*) and one transcriptome assembly (*Enallagma hageni*) have been published. Odonates have some of the most advanced visual systems among insects and several species are colour polymorphic, and genomic and transcriptomic data would allow studying the genomic architecture of these interesting traits and make detailed comparative studies between related species possible. Here, we present a comprehensive de novo transcriptome assembly for *I. elegans* built from short-read RNA-seq data. The transcriptome analysis in this paper provides a first step towards identifying genes and pathways underlying the visual and colour systems in this insect group. Results: Illumina RNA sequencing performed on tissues from the head, thorax and abdomen generated 428,744,100 paired-ends reads amounting to 110 Gb of sequence data, which was assembled de novo with Trinity. A transcriptome was produced after filtering and quality checking yielding a final set of 60,232 high quality transcripts for analysis. CEGMA software identified 247 out of 248 ultra-conserved core proteins as 'complete' in the transcriptome assembly, yielding a completeness of 99.6%. BLASTX and InterProScan annotated 55% of the assembled transcripts and showed that the three tissue types differed both qualitatively and quantitatively in *I. elegans*. Differential expression identified 8,625 transcripts to be differentially expressed in head, thorax and abdomen. Targeted analyses of vision and colour functional pathways identified the presence of four different opsin types and three pigmentation pathways. We also identified transcripts involved in temperature sensitivity, thermoregulation and olfaction. All these traits and their associated transcripts are of considerable ecological and evolutionary interest for this and other insect orders. Conclusions: Our work presents a comprehensive transcriptome resource for the ancient insect order Odonata and provides insight into their biology and physiology. The transcriptomic resource can

provide a foundation for future investigations into this diverse group, including the evolution of colour, vision, olfaction and thermal adaptation." (Authors)] Address: Chauhan, P., Dept of Biology, Lund University, Sölvegatan 37, SE-22362 Lund, Sweden. Email: pallavi.chauhan@biol.lu.se

14464. Collins, S.D. (2014): Fine-scale modeling of riverine Odonata distributions in the northerneast United States. Ph.D, Biology, Graduate Faculty of Texas Tech University: X + 207 pp. (in English) ["The distributions of riverine Odonata was modeled at the scale of individual river segments across the northeastern United States, a 784,982 km² region spanning from Ohio, West Virginia, and Virginia northeast to Maine. The species distribution modeling approach was reviewed with respect to Odonata, and several modeling techniques were compared. Species locality data assigned only to U.S. county is prevalent in invertebrate databases, and it was found that using these data for modeling tends to overpredict the geographic distributions of species. Several techniques to compensate for geographic sampling bias, which is also a characteristic of these largely opportunisticly collected databases, were compared, though the optimum method (thinning data, biased background sampling, or no treatment) depended on the dataset. Watersheds and riparian zones are ecologically relevant for riverine organisms, and models with catchment- and local-scale predictors outperformed models based only on climate. This fine-scale modeling approach is appropriate for the conservation of freshwater diversity, because individual river segments containing suitable species habitat can be identified and prioritized. Climate change is expected to reduce the available habitat for riverine Odonata within the northeastern U.S., though some rivers may serve as climatic refugia, and conservation of these rivers and their watersheds is essential." 14466. Corser, J.F.; White, E.L.; Schlesinger, M.D. (2014): Odonata origins, biogeography, and diversification in an Eastern North American hotspot: multiple pathways to high temperate forest insect diversity. *Insect Conservation and Diversity* 7(5): 393-404. (in English) ["We assessed the origins and historical biogeography of a rich regional odonate fauna in New York State (NYS), North-eastern United States. We computed North American (NA) range centres and NYS range margins and reviewed the taxonomic literature to provide a useful phylogenetic framework for the fauna. We analysed results from a newly completed Odonata atlas using generalised linear anova models to assess the effects of species' origins and zoogeographic affinities on relative frequency and extinction risk metrics. Phylogenetic reconstruction based on taxonomic nomenclature revealed different patterns of diversification. Zygoptera in NYS is mainly of Neotropical origin ~ 60 Ma displaying a pattern of tropical conservatism, but with a burst recent of Plio–Pleistocene speciation in certain groups. Alternatively, Anisoptera contains crown group endemic taxa and other very old lineages from the Mesozoic era before the breakup of Pangaea, highlighting the evolutionary significance of the Appalachian Mountains as an important global centre of temperate forest freshwater diversity. These high regional levels of odonate diversity have been brought about by at least three different mechanisms: dependence on forests, predominance of non-ecological speciation mechanisms, and niche conservatism across hundreds of millions of generations. NYS lies at a crossroads of both ancient and more recent Odonata evolution comprising separate boreal, temperate, and tropical faunas. Those species encountered less frequently and having higher overall extinction risk metrics generally tended to be the boreal species on the rear edge of their range, a widespread phenomenon for the insects of many regions generally attributed to ongoing climate change." 14467. Costa, R.N.; Nomura, F. (2014): Assessment risk and limited behavioral plasticity in tadpoles of *Rhinella ornata* (Anura, Bufonidae). *Iheringia* 104(2): 162-167. (in Portuguese, with English summary) ["Anuran tadpoles are important elements of trophic networks in aquatic environments, being food resource for many types of predators. Thus, the tadpoles exhibit a great variety of defense mechanisms that may be morphological, behavioral and/or physiological. The unpalatability, produced by the accumulation of toxic substances in the skin, is a common mechanism in many frog lineages. However, some predators are not affected by these toxic substances, which may favor the development of alternative mechanisms of defense against predation. In this context, our objective was evaluate if the unpalatable tadpoles of *R. ornata* (Spix, 1824) may present behavioral mechanisms of defense against predation in the presence of predators that are not

affected by toxic substances on its skin. To test our hypothesis, we used two kinds of predators: an aquatic Heteroptera of the genus *Belostoma* and a dragonfly larva of the genus *Aeshna*. The tadpoles were located in aquariums with visual and chemical clues of predators (direct risk experiment), only chemical clues (indirect risk experiment) and by the complete absence of predator signals (control). In both cases, the swimming behavior was observed for 5 minutes. During the experiments there was no alteration in swimming behavior of tadpoles." (Authors)] Address: Costa, R.N., Univ. 14468. Culler, L.E.; McPeck, M.A.; Ayres, M.P. (2014): Predation risk shapes thermal physiology of a predaceous damselfly. *Oecologia* 176(3): 653-660. (in English) ["Predation risk has strong effects on organismal physiology that can cascade to impact ecosystem structure and function. Physiological processes in general are sensitive to temperature. Thus, the temperature at which predators and prey interact may shape physiological response to predation risk. We measured and evaluated how temperature and predation risk affected growth rates of predaceous damselfly nymphs (*Enallagma vesperum*, Odonata: Coenagrionidae). First, we conducted growth trials at five temperatures crossed with two levels of predation risk (fish predator present versus absent) and measured growth rates, consumption rates, assimilation efficiencies, and production efficiencies of 107 individual damselflies. Second, we used a model to evaluate if and how component physiological responses to predation risk affected growth rates across temperatures. In the absence of mortality threat, growth rates of damselflies increased with warming until about 23.5 °C and then began to decline, a typical unimodal response to changes in temperature. Under predation risk, growth rates were lower and the shape of the thermal response was less apparent. Higher metabolic and survival costs induced by predation risk were only partially offset by changes in consumption rates and assimilation efficiencies and the magnitude of non-consumptive effects varied as a function of temperature. Furthermore, we documented that thermal physiology was mediated by predation risk, a known driver of organismal physiology that occurs in the context of species interactions. A general understanding of climatic impacts on ectothermic populations requires consideration of the community context of thermal physiology, including non-consumptive effects of predators." 14476. Drake, D.L.; Anderson, T.L.; Smith, L.M.; Lohraff, K.M.; Semlitsch, R.D. (2014): Predation of eggs and recently hatched larvae of endemic Ringed Salamanders (*Ambystoma annulatum*) by native and introduced aquatic predators. *Herpetologica* 70(4): 378-387. (in English) ["Predation is a key determinant of pond community structure, yet not all predators are equally effective and not all life stages of potential prey are similarly susceptible. Understanding the effects of native and introduced species is essential to informing management strategies, especially for endemic and species of conservation concern. We examined the effects of five common predators (three native: Central Newts [*Notophthalmus viridescens louisianensis*], aeshnid dragonfly naiads [Aeshnidae], and Southern Leopard Frog tadpoles [*Lithobates sphenoccephalus*]; and two introduced: Fathead Minnows [*Pimephales promelas*] and Mosquitofish [*Gambusia affinis*]) on survival of eggs and recently hatched larvae of Ringed Salamanders (*Ambystoma annulatum*). We also examined the effect of supplemental food or cover availability on survival at each stage. Predators primarily showed a binary response to eggs, consuming all or none of them. Supplemental food did not influence whether eggs or larvae were consumed. Larvae were consumed by all predator species although the effect varied. The presence of cover did not reduce the impacts of the other predators on larval survival. Overall, the two introduced fish species had a greater impact on survival of the early stages of Ringed Salamanders than did the native predators. Further inquiries into the susceptibility of different life stages and survival will improve conservation strategies for rare and endemic species such as Ringed Salamanders." 14477. Dumont, H.J. (2014): Odonata from the Tibesti Mountains and the Ounianga Lakes in Chad, with notes on *Hemianax ephippiger* accumulating in the desert. *Odonatologica* 43(1/2): 13-24. (in English) ["Fourteen species of Odonata were collected in Ounianga and Tibesti (Chad, Africa) in March 2014. Among them, only one zygopteran (*Ischnura saharensis*, with a Saharan distribution), one gomphid (the eremian *Paragomphus sinaiticus*), and two aeshnids (*Anax imperator* and *Hemianax ephippiger*) were present. The latter species was not only the most common dragonfly, but also the most abundant insect seen in the desert. It is likely that it was in a phase of accumulating individuals, possibly as a prelude to another

massive trans-Sahara and even trans-Mediterranean migration, for which the species is well-known. The 10 libellulids recorded were almost all Afrotropical species, but several expand to the Maghreb and even Mediterranean Europe. Only *Orthetrum* cf. *hintzi* is a tropical African species that had never been recorded from the desert before." (Author)] Address: Dumont, H.J., Univ. Gent, Inst. Animal Ecology, K.L. Ledeganckstraat 35, B-9000 Gent, Belgium. E-mail: Henri.Dumont@ugent.be

14478. Dziekonska-Rynko, J.; Rokicki, J.; Mierzejewska, K. (2014): In vitro infection experiments with eggs of the nematode *Contraecaecum rudolphii* Hartwich, 1964 (sensu lato) targeting aquatic insect larvae (Odonata: Coenagrionidae and Libellulidae; Trichoptera: Integripalpia) as possible intermediate hosts. *Oceanological and Hydrobiological Studies* 43(2): 165-169. (in English) ["The availability of aquatic insects (Odonata: Coenagrionidae, Libellulidae and Trichoptera: Integripalpia) as potential intermediate hosts for the nematode *Contraecaecum rudolphii* Hartwich, 1964 sensu lato was studied under laboratory conditions. The infective material consisted of nematode eggs, newly hatched larvae, as well as in vitro infected cyclopoid copepods. High prevalence and intensity of infection associated with a low mortality of aquatic insect larvae suggests that they may serve as intermediate hosts for *C. rudolphii* and constitute a major reservoir of *C. rudolphii* larvae in aquatic habitats." 14480. Eck, A.; Byrne, A.; Popescu, V.D.; Harper, E.B.; Patrick, D.A. (2014): Effects of water temperature on larval amphibian predator-prey dynamics. *Herpetological Conservation and Biology* 9(2): 302-308. (in English) ["Predation represents an important driver of species persistence and community structure. Climate change can influence predation through changes in the distribution and abundance of predatory species. Furthermore, predator-prey dynamics may be influenced by climate-induced shifts in the behaviour of predators and/or prey. Our research employed a model system consisting of larval amphibians

(*Lithobates clamitans*) as prey, and three species of predatory dragonfly larvae, *Ladona julia*, *Aeshna interrupta*, and *Didymops transversa*. Our goal was to assess whether simulated climate-induced changes in predator assemblages and abiotic conditions may influence predator-prey dynamics. The study was conducted in replicated aquatic microcosms, with water temperature manipulated across a range of temperatures. Predation studies involved a single dragonfly of a focal species and 10 larval *L. clamitans*. Our best-fitting model included dragonfly species, water temperature, and the interaction between the two factors. Survival of anuran larvae decreased for both *Aeshna interrupta* and *Didymops transversa*, but remained constant with increasing water temperature for *Ladona julia*. Our study demonstrates the potential for climate-induced changes in the composition of predator species to interact with altered abiotic conditions in shaping predator-prey dynamics." 14482. Escoto-Moreno, J.A.; Márquez, J.; Novelo-Gutiérrez, R. (2014): Los odonatos (Insecta: Odonata) del estado de Hidalgo, México: situación actual y perspectivas. *Revista Mexicana de Biodiversidad* 85: 1043-1053. (in Spanish, with English summary) ["The odonates (Insecta: Odonata) from Hidalgo state, Mexico: present situation and perspectives: An historical analysis on the number of odonate species recorded for Hidalgo State is made. Moreover, collections were made in 2011 year, in 8 localities with cloud forest, during the dry and rainy seasons, twice each, complemented with occasional collections in other 8 localities with other type of forests along 2012-2013 years. Twenty-two new records of species are provided, increasing the total number of odonates for Hidalgo to 129 species. A map of the historical collection sites, as well as those places with a high potential species richness, was generated using geographic information system (GIS), indicating also the areas with high potential for new records for future studies in the state. For Mexico, Hidalgo occupies the fifth place in odonate diversity per km² and the sixth one in odonate species richness, representing more than 1/3 of the species known for the country, and more than 1/2 and 3/4 of the genera and families recorded

for Mexico, respectively. Finally, comments are made on the high odonate diversity and its probable cause." 14484. Farkas, A.; Danyik, T.; Mora, A. (2014): Contribution to the Odonata fauna of the rivers in the Körös-Maros National Park, Hungary, with special emphasis on Gomphidae. Part I. *Acta Biol. Debr. Oecol. Hung.* 32: 31-49. (in English, with Hungarian summary) ["In 2013 systematic collections of Gomphidae exuviae were carried out at 37 sampling sites along the Hungarian sections of the Fehér-Körös, Fekete-Körös, Kettos-Körös and Maros rivers. The sampling sites were visited four times, taking into account the phenology of gomphid species. Besides Gomphidae, exuviae of other species were also collected with faunistic aims. In addition, observational data on adult specimens were occasionally recorded. Collections resulted in the occurrence of 5640 exuviae (from which 5291 were exuviae of Gomphidae) and 112 adults were observed. Altogether 17 species were found, for which detailed records are given. The most important result is the co-occurrence of the four Hungarian gomphid species along all studied rivers. The distributional areas of *Onychogomphus forcipatus* and *Ophiogomphus cecilia* were remarkably expanded by our results. The composition of the Gomphidae assemblages varied widely among rivers and within a given river as well, according to habitat characteristics. In conclusion, stable and viable populations of Gomphidae exist along the studied rivers (Fehér-Körös may be an exception) with great significance in terms of nature conservation. Accordingly, either these populations or rivers deserve strict protection." (Authors)] Address: Farkas, Anna, Department of Hydrobiology, Centre of Arts, Humanities and Sciences, Faculty of Science and Technology, University of Debrecen, Egyetem tér 1, H-4032 Debrecen, Hungary. (2014): New EPIC nuclear DNA sequence markers to improve the resolution of phylogeographic studies of coenagrionids and other odonates. *International Journal of Odonatology* 17(2-3): 135-147. (in English) ["While phylogeographic data provide valuable information to inform conservation plans, there are comparatively few Odonata phylogeographic studies. This lack of research is partially due to a lack of independent DNA markers with appropriate levels of polymorphism that PCR-amplify in a range of species. We followed an exon-primed, intron-crossing (EPIC) PCR strategy to develop five new, polymorphic nuclear DNA sequence loci (six distinct DNA fragments) for *Coenagrion mercuriale*. These markers were: cell division cycle 5 protein (CDC5), arginine methyltransferase (PRMT), acetylglucosaminyl-transferase (AgT), myosin light chain (MLC) and phosphoglucose isomerase (PGI). Between three and five of these new markers could be PCR-amplified in five other species from the genus *Coenagrion*; one locus (PRMT) can be used in 26 other species of odonates that we examined, including three species of Anisoptera belonging to the genus *Onychogomphus*. These new nuclear genetic markers will be useful for phylogeographic studies in a range of odonate species, but also for phylogenetic studies, providing a particularly useful complement to the existing mitochondrial and nuclear loci." Argentino Cienc. Nat.*, n.s. 16(2): 115-122. (in Spanish, with English summary) [La Laguna Blanca, Parque Nacional Río Pilcomayo, provincia de Formosa (25° 09' 56,80" S - 58° 14' 21,28" W), Argentina. "Diet of the electric knife-fishes, *G. omarorum*, is described in Laguna Blanca Río Pilcomayo National Park, Formosa province. Samples were collected monthly from September 2012 to July 2013. For the analysis of stomach contents, frequency methods, volume fraction, percentage and numerical abundance index (AI) were used. Preys ingested generally belong to invertebrates (including Odonata) and fish that live under the floating plants. The specimens of smaller sizes to 200 mm total length (TL) had a carnivorous diet with greater specialization, while in larger sizes from 201 mm TL, was carnivorous diet of the generalist type. Increased consumption of fish and decapods with increasing LT was observed. Insects in general and in particular Odonata nymphs, dominate in small and medium sizes. Significant differences were observed in the diet of this species throughout the period considered, correlating the same with changes in biomass of floating plants. The results allow characterizing the diet of *G. omarorum* as a generalist." 14489. Fuller, C. (2014): The effects of atrazine and predation risk on larval dragonflies *Ladona deplanata* (Odonata: Libellulidae). Thesis, Murray State University: 67 pp. (in English) ["Ecologists have recognized that the effects of anthropogenic stressors on organism life history may be magnified when combined with natural forms of stress. However, very few studies examine the effects on physiological traits in addition to traditional life history traits. Here, I review the usage, environmental concentrations and effects of atrazine, a common herbicide in aquatic systems. Then I present my study on the interactive effects of atrazine, and predation risk on growth, mass, immune function, and energy storage in the larval dragonfly *L. deplanata*. Using aquatic mesocosms to simulate natural conditions, I used a repeated measures design assessing sublethal atrazine exposure and non-consumptive predator stress on these traits over a 45-day period during the larval stage. I predicted that combining these stressors would

have additive negative effects on immunity and growth. I found that predation risk and atrazine caused significant changes to immunity over time, the strength of which was dependent on the specific immune parameter measured. Predation risk increased immune function, which was partially explained by mass gain but not skeletal growth, whereas sublethal atrazine caused little immunosuppression. The results of this study indicate that atrazine interacts with predation risk over time to cause significant changes to immune function but not growth and mass gain in *L. deplanata*. Together, these stressors may be altering the ability of larvae to survive to metamorphosis, which may profoundly affect population and community dynamics." (Author)] Address: Fuller, Claire, A., Dept of Biology, Murray State University, Murray, KY 42071, USA. E-mail: claire.fuller@murraystate.edu

14490. Furness, A.N.; Soluk, D.A. (2014): Why shouldn't the dragonfly cross the road? Factors that influence dragonfly vulnerability to vehicular collisions. 99th ESA Annual Meeting (August 10 -- 15, 2014): (in English) [Verbatim: Roadway impacts on mammals, amphibians, and reptiles and how to mitigate for them has been widely examined; however, the impacts roadways have on insects has rarely been addressed. Roadways are known to act as barriers to wildlife movement either by eliciting behavioral avoidance or causing direct mortality. This is of special concern for endangered species such as the Hine's emerald dragonfly (*Somatochlora hineana*), large numbers of which die along roadways in some parts of its range. One of the simplest ways to reduce mortality is to reduce vehicle speed and likelihood of fatal collisions; however, virtually nothing is known about the relationship between vehicle speed and mortality in insects. We conducted a controlled experimental evaluation comparing the rates of dragonfly-vehicle collisions at 24 kph (15 mph), 40 kph (25 mph), 56 kph (35 mph), 72 kph (45 mph), and 88 kph (55 mph) on roadways in northern Door County, Wisconsin. Our study evaluated the influence of motor vehicle speed, flight height, and flight behavior on mortality rate of adult dragonflies in ten identified genera. Results/Conclusions: Our results indicate that vehicle speed was the most significant predictor ($p < 0.0001$) of encounter result. There was a strong non-linear structure to the relationship between vehicle speed and mortality, suggesting that reducing vehicle speed is most important at higher speeds and would have fewer benefits at lower speeds. Flight height was not a strong predictor of encounter result ($p = 0.72$); however, results show a significant difference ($p < 0.0001$) between the encounter results of straight-flying dragonflies (e.g. *Somatochlora*, *Anax*) and all others, with straight fliers most vulnerable and agile fliers (e.g. *Pantala*, *Tramea*) least vulnerable. For dragonflies in general, decreasing the speed limit from 88 kph (55 mph) to 72 kph (45 mph) has the potential to reduce the probability of hit by 17%. For *S. hineana*, this speed reduction could decrease their probability of hit from 65% to 27%. Although many wetland insects have short-lived adults, some especially sensitive groups have adults that forage, reproduce, and disperse

over an extended period of time. Speed reduction in areas where these sensitive species interact with motor vehicles may be an essential tool in their conservation and may help reduce the overall impact of roadways on wetland ecosystems.] Address: Furness, Amber, Biology, University of South Dakota, Vermillion, SD, USA

14491. Futahashi, R. (2014): The adult flight season with the first and last appearance dates of Japanese dragonflies. *Aeschna* 50: 145-181. (in Japanese, with English summary) ["I summarize adult flight season of Japanese dragonflies based on literatures and personal communications. I also listed up the first and last appearance dates especially in the following well-investigated prefectures: Hokkaido, Aomori, Tochigi, Toyama, Shiga, Mie, Nara, Tokushima, Ehime, Kochi, and Oita." 14493. Gambale, P.G.; Batista, V.G.; Oda, F.H.; Campos, R.M.; Takemoto, R.M.; Bastos, R.P. (2014): Anuran larvae as prey and hosts of invertebrates in Neotropical aquatic habitats. *Revista Chilena de Historia Natural* 87(31): 5 pp. (in English) ["Background: Biotic processes, such as predation and parasitism events, are crucial for answering questions in ecology and evolution. Here, we report predation and ectoparasitism events of invertebrates upon tadpoles in aquatic habitats of southern Brazil. Findings: Four lentic water bodies were sampled twice a month (December 2012 to March 2013). Those water bodies were located in the Diamante do Norte, County, state of Paraná, southern Brazil. The tadpoles, *Dendropsophus minutus*, *Hypsiboas raniceps*, *Scinax fuscovarius*, *Physalaemus cuvieri* and *Elachistocleis bicolor* were observed being predated by six different invertebrate predators. However, *Leptodactylus fuscus* and *Pseudis* sp. were also recorded on the same water bodies and were not observed being preyed or parasitized. The most abundant predator in our sampling areas was the diving beetle larvae. We observed

a static and escape behaviour of tadpoles when in close proximity to predators and constant movements in *E. bicolor* tadpoles, which can be advantageous for invertebrate predators. Parasitism events included *D. minutus*, *S. fuscovarius*, and *E. bicolor* tadpoles that were infected by a single leech. The ectoparasites anchor the posterior sucker on the host tadpole during the blood feeding. Conclusions: Even isolated reports of ecological interactions are important for understanding ecological communities and the impacts of parasites and predators on tadpoles' populations. Additionally, these interactions can help to understand the ecology behaviour of the organisms." (Authors) In one case *Coryphaeschna* sp. was found to prey on *Elachistocleis bicolor*.] Address: Gambale, Priscilla, Depto de Biol., Univ. 14495. Graf, R. (2014): Rohrkolbenanbau - eine Chance für die Artenvielfalt?. *Orn. Beob.* 111(2): 93-106. (in German, with English summary) ["Cattail *Typha* sp. is a productive marsh plant which has been traditionally used for various purposes. Recently, additional usages of this plant have been developed, particularly regarding energy recovery. Therefore, a 1-hectare Cattail trial plot was established adjacent to a nature reserve in Central Switzerland (Wauwilermoos, Canton of Lucerne) in 2007. The plot is flooded every year to a height of 20-60 cm from April to the end of August and drained over winter. Since Cattail fields are morphologically very similar to natural marshes, a two-year monitoring programme was started to investigate how such fields were used by water and swamp-dwelling bird species. Supplementary data were drawn from the national wetland breeding bird census as well as the rare breeding and visiting bird census of the Swiss Ornithological Institute. It was shown that various bird species benefitted during migration time, primarily smaller herons, Common Teal, Garganey and rail species. Marked differences were observed in the species spectrum between the first and second year of the study, as Cattail had grown ample rapidly and the vegetation thus changed. The Cattail field was used by 11 marsh and water bird species, for eight of them (Mallard, Little Grebe, Spotted

Crake, Common Moorhen, Coot, Reed Warbler, Marsh Warbler and Reed Bunting) "Probable Breeding" was noted. Surveys on further organism groups revealed positive effects for dragonflies, water frogs and the Grass Snake. Cattail can be cultivated on sites which are prone to re-wetting (mostly former moorland) where it is an interesting crop to grow as it combines characteristics of high-quality biodiversity promoting areas with those of agricultural production." (Author) Also Odonata were monitored. 31 species were recorded between 2007 and 2008, including regionally rare species as *Anax ephippiger* and *Orthetrum albistylum*.] Address: Graf, R., Schweizerische Vogelwarte, Seerose 1, 6204 Sempach, Switzerland. 14497. Green, D.J. (2014): Dispersal, population genetics and taxonomy of selected aquatic macroinvertebrates in ephemeral river systems. M.Sc. thesis, School of Biological Sciences, Faculty of Science and Engineering, Flinders University, Adelaide, South Australia: 182 pp. (in English) ["One of the challenges to the study macroinvertebrates has always been identification. We looked at two morphologically very similar damselflies, *Ischnura heterosticta* and *Austroagrion watsoni* to investigate the benefit of genetic techniques in species identification (chapter 5). The mitochondrial sequence showed the rate of incorrect morphological identification at approximately 50%. This highlights both the need for accurate identification as well as the power of genetic techniques for identifying morphologically similar species." (Author)] Address: not stated

(2014): Behavior of the Amazonian damselfly *Chalcopteryx scintillans* McLachlan (Zygoptera: Polythoridae) and comments on its morphological distinction from *C. rutilans* (Rambur). *International Journal of Odonatology* 17(4): 251-258. (in English) ["Polythorid damselflies are Neotropical stream dwellers, whose behaviour has rarely been recorded. Here we describe the territorial and courtship behaviour of *Chalcopteryx scintillans* McLachlan, an Amazonian damselfly with shiny copper-coloured hind wings. Territorial behaviour consists of aerial contests, when males engage in threat displays and mutual pursuits in ascending and rocking flights. During courtship, males hold their coppery hind wings still while hovering with their forewings, showing the hind wings to females, which hover in front of the male in response. After copulation, the male exhibits the courtship flight again by hovering over the oviposition resource (i.e. fallen tree trunk) on the stream. The females oviposit on the trunk while the males guard them by perching near and hovering around them constantly. We also present behavioural notes on reproductive and oviposition behaviour, and comments on the differentiation between *C. scintillans* and *C. rutilans* (Rambur)."] (Authors)] Address: Guillermo-Ferreira, R., Fac. de Ciências Biológicas e Ambientais, Univ. 14500. Hall, A.M.; McCauley, S.J.; Fortin, M.-J. (2014): Recreational boating, landscape configuration, and local habitat structure as drivers of odonate community composition in an island setting. *Insect Conservation and Diversity* 8(1): 31-42. (in English) ["1. Anthropogenic impacts to aquatic and terrestrial ecosystems are ubiquitous. Among these, local impacts to freshwater coastal wetlands from recreational boating are potentially severe. We determine the relative contribution of natural factors (local habitat structure and landscape configuration) and estimated impact from anthropogenic factors (i.e. pressure from recreational boating) to odonate community composition. 2. Odonate adults and exuviae were sampled from 17 islands within the 30 000 islands of the Georgian Bay Region of Lake Huron (Ontario, Canada). These islands experience a gradient of boating pressure from four marinas. The magnitude of impacts due to anthropogenic factors was estimated by marina dock space, proximity to marked boating channels, and proximity to a major highway. 3. Redundancy analyses and variance partitioning were utilised to quantify the relative influence of local habitat structure,

landscape configuration, and anthropogenic pressures on the distribution of 18 odonate species. 4. Our results show that local habitat structure, landscape configuration, and boating pressures influence odonate community composition. Overall variance in the species composition explained was 36.5% for adults (25.3% landscape configuration and habitat structure, 6.0% boating pressure, 5.2% shared) and 21.9% for exuviae (13.2% landscape configuration and habitat structure, 6.9% boating pressure, 1.8% shared). We found that communities of adults and larvae (sampled as exuviae) are influenced by different factors. 5. Overall, we find evidence that odonate community composition is affected by boating pressures. This stresses the need to consider not only global-scale human disturbances in conservation planning but also localised effects which differentially impact major life stages." 14501. Henn, M.; Nichols, H.; Zhang, Y.; Bonner, T.H. (2014): Effect of artificial light on the drift of aquatic insects in urban central Texas streams. *Journal of Freshwater Ecology* 29(3): 307-318. (in English) ["Light pollution can reduce night time drift of larval aquatic insects in urban streams by disrupting their circadian rhythms. Previous studies on larval insect drift show that disruption in drift leads to changes in reproduction as well as intraspecific and interspecific interactions. The purpose of this study was to conduct a preliminary investigation into the effects of extreme artificial light on insect drift in urbanized, high clarity spring systems of the karst Edwards Plateau, TX. We quantified taxa richness, diversity, and abundance in aquatic insect night time drift under two treatments (ambient night time light and artificial light addition) and among five streams using a paired design. Richness and diversity of drifting aquatic insects were similar between treatments but abundance was 37% less in the light addition treatment than that of the control. Effects of light addition on mean abundance was more notable in large streams with a 58% decrease in Simuliidae (compared to that of the control) and 51% decrease in Baetidae. Reduced drift from light addition suggests the potential of artificial lighting disrupting insect drift and consequently community structure. Results of this experiment support a growing body of knowledge on how urbanized systems influence stream communities." 14502. Henry, J.R.; Harrison, J.F. (2014): Body size effects on the oxygen-sensitivity of dragonfly flight. *Journal of Experimental Biology* 217: 3447-3456. (in English) ["One hypothesis for the small size of insects relative to vertebrates, and the existence of giant fossil insects, is that atmospheric oxygen levels constrain insect body sizes because oxygen delivery is more challenging in larger insects. This study tested this hypothesis in dragonflies by measuring the oxygen sensitivity of flight metabolic

rates and behavior during hovering for 11 species of dragonflies (*Aeshna multicolor*, *Anax junius*, *Libellula comanche*, *L. luctuosa*, *L. saturata*, *Macrodiplax balteata*, *Pachydiplax longipennis*, *Pantala flavescens*, *P. hymenaea*, *Tramea lacerrata*, *T. onusta*) that ranged in mass by an order of magnitude. We measured flight times and flight metabolic rates in seven oxygen concentrations ranging from 30% to 2.5% to assess the sensitivity of their flight to atmospheric oxygen. We also assessed the oxygen sensitivity of flight in low-density air (nitrogen replaced with helium) in order to increase the metabolic demands of hovering flight. Lowered atmospheric densities did induce higher flight metabolic rates. Flight behavior was more sensitive to decreasing oxygen levels than flight metabolic rate. The oxygen sensitivity of flight metabolic rates and behaviors were not correlated with body size, indicating that larger insects are able to maintain an oxygen supply-to-demand balance even during flight." (Authors)] Address: Henry, Joanna, Arizona State Univ., PO Box 874701, Tempe, AZ 85287, USA. E-mail: joanna.henry@asu.edu

14503. Honcu, M. (2014): Records of the dragonfly *Leucorrhinia caudalis* (Charpentier, 1840), (Odonata, Libellulidae) of Česká Lípa Region (Czech Republik). *Bezdez* 23: 213-232. (in Czech, with English and German summaries) ["This paper discusses the records of *L. caudalis* in the water reservoirs at the airport near the former military training area Ralsko, Česká Lípa region. One male was detected on 20 May 2012 [...]. This record represents the fourth known locality in the Czech Republic and was made 50 years after the first detection of this species in Czech Republic. At present it represents the single recent locality in the Czech Republic because it repeatedly had not been detected in its historic localities. Therefore, in the Red list of Invertebrates of the Czech Republic by Farkac, Král & Škorpík (2005) it was considered as extinct. By further investigations it was proved that the population of *L. caudalis* in this locality is viable and evidently increases in number. The locality is endangered by old environmental burdens, succession, overgrowing and overshadowing, and, last not least, by different activities of sporting character which newly are spreading out in the surroundings of the former Hradcany airport. For the protection of this species and of the whole biocenosis the State Nature Protection Board is preparing a protection of the area with the water reservoirs by adding it to the already existing Nature Reserve Hradcanské rybníky (Ponds of Hradcany)." (in Chinese, with English summary) [Between 2009 and 2013, in Chongqing Jinpo National Nature Reserve (Nanchuan, Chongqing, China), 50 odonate species, belonging to 27 families have been recorded. Six species are new additions to the regional fauna. 40% (n=20) are

Palaearctic-Oriental, 34 % (n=17) species are Oriental, and 24% (N=13) are cosmopolitan distributed species.] Address: Hong, Z.-c., The Natural History Museum of Chongqing. Chongqing 400700, China

14505. Huang, S.-c. (2014): Colour vision of *Ischnura heterosticta* (Insecta: Odonata): Role in sexual selection, communication and visual plasticity. PhD Thesis, Queensland Brain Institute, University of Queensland. doi:10.142-64/uql.2014.469. 202 pp. (in English) ["Sensory systems are important for any life task of an animal. Vision, and colour vision in particular, is essential for visual-based insects, such as Odonata (damselflies and dragonflies), many of which display colour patterns on their bodies. Numerous behavioural studies suggest that the diverse colour patterns function as a means for intersexual, intrasexual, interspecific, or intraspecific recognition and play a role in sexual selection, particularly in ischnuran damselflies that have sex-limited polymorphism. However, to date there are no comprehensive studies linking behavioural to electrophysiological evidence to support the role of colour patterns and colour vision in mate choice in this group of insects. In my Ph.D. thesis, I investigated the function of body colouration and colour vision in sexual selection and communication of the Australian polymorphic damselfly, *Ischnura heterosticta*, and examined the mechanisms underlying its colour vision and colour discrimination ability. In an observational study (Chapter 2), I surveyed *I. heterosticta* reproductive behaviours and daily activity patterns in the field, providing the first detailed account of their colour morphs and behavioural biology. Andromorph females are blue like males, and gynomorph females have colour morphs in green, intermediate, and grey. Mating pairs, usually with gynomorphs, are formed after dawn and mating can last up to 3-4 hours. Oviposition occurs in the days after mating, and ovipositing females are subjected to aggressive male harassment, which varies with female colouration. These data provided the biological foundation regarding colour-based sexual selection in *I. heterosticta* investigated in the following chapters. In the next set of experiments (Chapter 3), I discovered a unique irreversible ontogenetic colour change in females of *I. heterosticta*: blue andromorphs are sexually immature individuals that emerge from nymphs. After 4 to 7 days, they turn into green-grey gynomorphs to signal their sexual maturity and advertise readiness to mate. Gynomorphs are the preferred mating partners, which suggests that blue andromorphs avoid unnecessary long mating during sexual immaturity through their male-mimicking colouration. This discovery provided the first indication that colour plays a key role in mate choice and that female polymorphism in *I. heterosticta* may be maintained via colour signals. In the next study (Chapter 4), I tested whether and how male mating preference was associated with colour cues by manipulating female body colours artificially. The outcomes strongly suggest that female body colouration is the key visual signal for mate choice in *I. heterosticta*. Males always preferred gynomorph females irrespective of female ratio or prior mating experience. Only under low

ambient light males of *I. heterosticta* occasionally misidentified blue andromorphs as mating partners, likely as consequence of the insufficient light. This finding provided the behavioural indication that ischnuran damselflies rely on colour vision for mate recognition. The next study (Chapter 5) examined the morphological structure of the compound eyes of *I. heterosticta* using histological approaches. The diameter of an ommatidium is about 10 μm , and its length can be up to 400 μm depending on the area of the retina. Several retinula cells were identified distributed along the ommatidium. This provided essential background information on the visual anatomy in this species, and the anatomical indication that *I. heterosticta* may have colour vision, which was investigated in the next chapter. I used electrophysiological approaches (Chapter 6) to investigate the spectral sensitivities of the visual system of *I. heterosticta*. The results showed that they have trichromatic vision, being able to detect UV, blue and green light. Contrast calculations confirmed that their colour discrimination ability enables them to distinguish the spectral differences of individual female morphs. These results were congruent with the behavioural findings from previous chapters, showing that *I. heterosticta* use colour signals for mate choice in context of sexual selection. The final study (Chapter 7) examined the molecular basis of colour vision in *I. heterosticta*, and investigated whether it is plastic and dependent on light experience. I identified three types of opsin genes in *I. heterosticta*, corresponding to three wavelengths of light (UV, blue and green), confirming that this species is trichromatic. I found that during development opsins are differentially expressed in nymphs (aquatic) and adults (terrestrial/aerial), and opsin expression also changes when individuals are reared or kept under different ambient light conditions. These findings were further supported by electrophysiological experiments, showing an equivalent change in response. This demonstrates that colour vision in *I. heterosticta* is plastic and that ambient light induces visual plasticity. This plasticity facilitates adaptation to the changing visual environments during development, and ensures that adults can detect the crucial colour cues that are key for mate choice and reproduction. This thesis is the first comprehensive study examining the functional role of colour vision and body colouration in a polymorphic ischnuran damselfly. This body of work also contributes important new insights into the mechanisms underlying sexual selection, evolution and maintenance of female-limited polymorphism in *I. heterosticta*." 14507. Ichikawa, Y.; Watanabe, M. (2014): Changes in the number of eggs loaded in *Pantala flavescens* females with age from mass flights (Odonata: Libellulidae). *Zoological Science* 31(11): 721-724. (in English) ["The wandering glider dragonfly *Pantala flavescens* migrates to Japan every spring, where the population increases until autumn, in which mass flights often occur, followed by death in the winter. There have been no reports to date on the maturation process of this species throughout its lifespan in Japan. We collected females from mass flights when the flight height was low, and classified them into seven age stages by examining their wing condition. Very few females of the older stage were collected from the mass flights. The wing condition corresponded with the change in body color and with the egg production process in the ovaries. While pre-reproductive-stage females did not release eggs when treated with our artificial oviposition technique, each reproductive-stage female released about 640 eggs. Nearly all eggs released were fertilized. The ovaries developed with the stage, and reproductive-stage females had about 1100 ovarioles. The estimated maximum fecundity was about 29,000 eggs. The lifetime number of eggs laid of *P. flavescens* should be revealed by dissection." (Authors)] Address: Watanabe, M., College of Biol. Sci., Univ. of Tsukuba, Tsukuba, Ibaraki 305-8572, Japan. 14508. Inamuro, T.; Minami, K.; Suzuki, K. (2014): Free flight simulations of a dragonfly-like flapping wing-body model by the immersed boundary-lattice Boltzmann method (Abstract: L6.00010). *Bulletin of the American Physical Society*, 67th Annual Meeting of the APS Division of Fluid Dynamics, Volume 59, Number 18, Sunday–Tuesday, November 23–25, 2014; San Francisco, California: (in English) [Verbatim: Free flights of the dragonfly-like flapping wing-body model are numerically investigated by using the immersed boundary-lattice Boltzmann method (IB-LBM). First, we simulate free flights of the model without the pitching rotation for various values of the phase lag angle ϕ between the forewing and the hindwing motions. We find that the wing-body model goes forward in spite of ϕ , and the model with $\phi = 0^\circ$ and 90° goes upward against gravity. The model with $\phi = 180^\circ$ goes almost horizontally, and the model with $\phi = 270^\circ$ goes downward. Secondly, we simulate free flights with the pitching rotation for various values of the phase lag angle ϕ . It is found that in spite of ϕ the wing-body model turns gradually in the nose-up direction and goes back and down as the pitching angle

Oc increases. That is, the wing-body model cannot make a stable forward flight without control. Finally, we show a way to control the pitching motion by changing the lead-lag angle $\gamma(t)$. We propose a simple proportional controller of $\gamma(t)$ which makes stable flights within $Oc = \pm 5^\circ$ and works well even for a large disturbance.] Address: not stated

14509. Jäckel, K.; Prinzhorn, S.; Falk, J., Deichmann, A.; Willigalla, C.; Koch, K. (2014): Nächtliche Ruheplätze der Odonata, insbesondere der Arten *Ischnura elegans* und *Coenagrion pulchellum* (Odonata). *Libellula* 33(1/2): 113-126. (in German, with English summary) ["Roosting habitats of Odonata, in particular of *Ischnura elegans* and *Coenagrion pulchellum* (Odonata) – Odonates use different habitats for maturing, mating, foraging, and roosting. There is not much knowledge about the odonates' choice of habitat for roosting at night. In our study we investigated two potential nocturnal roosting sites. We investigated whether individuals were clustering for roosting and whether there existed any preferences in the choice of the roosting site depending on the odonates' gender. Locations of our study were an assemblage of artificial ponds at the Johannes Gutenberg-University Mainz and a lake in the nature reserve "Eich-Gimbsheimer Altrhein", situated between Mainz and Worms. The investigation took place in June and July 2013. In the night, we found remarkably less species of Anisoptera and Zygoptera than during the day. Compared to Anisoptera, Zygoptera preferred to roost in lower positions. At both studied sites we mainly found a lot of individuals of *Ischnura elegans* and *Coenagrion pulchellum*. Both species favoured roosting on the top of the substratum at the waters' edge and on a marsh area next to the water. It seemed that male and female odonates did not choose the roosting position on the substratum in an obviously different way. 34-40 % of the odonate species found roosted in clusters. In both species the sex ratio within the roosting aggregations was biased towards males. Among separately roosting individuals of *C. pulchellum* we found a larger number of males, whereas for *I. elegans* the sex ratio was balanced." 14510. Janssens, L.; Stoks, R. (2014): Reinforcing effects of non-pathogenic bacteria and predation risk: from physiology to life history. *Oecologia* 176(2): 323-332. (in English) ["The important ecological role of predation risk in shaping populations, communities and ecosystems is becoming increasingly clear. In this context, synergistic effects between predation risk and other natural stressors on prey organisms are gaining attention. Although non-pathogenic bacteria can be widespread in aquatic ecosystems, their role in mediating effects of predation risk has been ignored. We here address the hypothesis that non-pathogenic bacteria may reinforce the negative effects of predation risk in larvae of the damselfly *Coenagrion puella*. We found synergistic effects for all three life history variables studied: mortality increased, growth reductions

were magnified and bacterial load was higher when both non-lethal stressors were combined. The combined exposure to the bacterium and predation risk considerably impaired the two key antipredator mechanisms of the damselfly larvae: they no longer reduced their food intake under predation risk and showed a synergistic reduction in escape swimming speed. The reinforcing negative effects on the fitness-related traits could be explained by the observed synergistic effects on food intake, swimming muscle mass, immune function and oxidative damage. These are likely widespread consequences of energetic constraints and increased metabolic rates associated with the fight-or-flight response. We therefore hypothesize that the here documented synergistic interactions with non-pathogenic bacteria may be widespread. Our results highlight the ignored ecological role of non-pathogenic bacteria in reinforcing the negative effects of predation risk on prey organisms." 14517. Kijowski, A.M. (2014): Habitat use and movement patterns in larvae of the endangered Hine's emerald dragonfly (*Somatochlora hineana*, Williamson). M.Sc. thesis, University of South Dakota: 66 pp. (in English) ["Aquatic invertebrates living within wetlands must be able to respond to annual, seasonal, or even daily environmental fluctuations. In the spring, aquatic invertebrates may move to exploit available newly flooded areas. If such movement occurs, they must be able to follow the retreating water or have some other mechanism to avoid desiccation. The larvae of *Somatochlora hineana* live in flowing channels in seasonally flooded wetlands; however, it is unclear whether they use the wetland more extensively. To investigate the potential seasonal and yearly changes in *S. hineana* distribution and abundance in response to environmental variation, data from field studies from 2011-2012 were analyzed. There were 210 *S. hineana* larvae collected from the Mud Lake North Wildlife Refuge Area in Door County, Wisconsin from within and outside of crayfish burrows during the spring and summer. The mean densities of *S. hineana* larvae outside of burrows varied between May and June 2012, but did not vary across a habitat gradient. There were no significant changes in mean *S. hineana* densities in burrow and benthic samples between June 2011 and June 2012. In order to gain a better understanding of how *S. hineana* respond to environmental variation, their movement patterns in response to fluctuating water levels, position within the habitat, and increased habitat connectivity were also examined. Larvae were collected and tagged in a series of marking studies in 2011 and 2012 at the Mud Lake North Wildlife Refuge. The average total distance (\pm sd) moved by *S. hineana* larvae for both summers was 1.15 ± 2.20 m/day with the longest net displacement being 11m/day. Larvae were observed moving between off-channel and within channel habitats, and were also caught in drift nets during periods of inundation, indicating increased habitat connectivity plays a role in the movement of these larvae." 14518. Kim, D.G.; Lee, C.Y.; Choi, L.J.; Kang, H.J.; Baek, M.J.; Kim, J.G.; Bae, Y.J. (2014): Drought effects on the colonization of benthic macroinvertebrate communities in the early successional phases in experimental mesocosm wetlands. *Journal of Freshwater Ecology* 29(4): 507-524. (in English) ["We investigated the drought effects on the colonization rate and pattern of benthic macroinvertebrate communities in newly created mesocosm wetlands in the central Korean Peninsula, from June 2011 to June 2013. The comparison was made between the initial colonization after mesocosm construction (pre-drought) and the recolonization after a drought event (post-drought) with a drought period of 50 days between them. In addition, we categorized communities according to their biological traits in relation to drought. Our results showed that aquatic vegetation abundance and covering degree were higher in post-

drought than in pre-drought, thereby influencing rapid colonization. Drought-resistant benthic macroinvertebrates colonized rapidly in post-drought; consequently, the colonization speed was 2.5-fold higher in post-drought than in pre-drought. We classified the benthic macroinvertebrate taxa into three groups: (1) a resistant group which generally emerged after the initial colonization period (e.g., Mollusca, Turbellaria, and Oligochaeta); (2) a sensitive group with diverse life history strategies and biological traits such as active migration or population decline after drought disturbance (e.g., Diptera: Chironominae, Odonata: Orthetrum, Coleoptera: Agabus and Rhantus); and (3) a seasonal group, which emerged only during certain periods and were not markedly influenced by drought (e.g., Ephemeroptera: Cloeon, Diptera: Culicidae, Odonata: Zygoptera and Pantala). Our findings elucidated the effects of drought on benthic macroinvertebrate communities in wetlands by using a mesocosm experiment." 14519. Kiss, O.; Elek, Z.; Moskát, C. (2014): High breeding performance of European Rollers *Coracias garrulus* in heterogeneous farmland habitat in southern Hungary. *Bird Study* 61(4): 496-505. (in English) ["Capsule: Rollers showed slightly higher breeding performance in farmland mosaics than in natural grasslands in southern Hungary, where both habitats were supplied with nest-boxes. Aim: To establish which factors affect Rollers' breeding success in agricultural and their more traditional grassland habitats. Methods: Rollers' reproductive success in farmland mosaics and grassland habitats were compared. Laying date, clutch size, feeding rate, as well as prey abundance and diversity, as estimated by sweep netting and pitfall trapping, were evaluated. Their effects on breeding performance were analysed by generalized linear models. Results: In the agricultural habitat Rollers showed an even higher reproductive output than in their traditional habitat of natural grassland. Prey composition showed differences between the two habitats, with the lower abundance of orthopterans in farmland mosaics being substituted by the higher abundance of coleopterans and the diversity of arthropods (Orthoptera, Coleoptera, Heteroptera, Arachnida, Hymenoptera, Lepidoptera, Diptera, Homoptera, Mantidae, Myrmeleonidae and Odonata). Conclusion: Rollers can reproduce well where good quality resources are available, even outside of their typical habitat, where nest-box erection schemes may benefit this threatened species." 14522. Kofler, I.M. (2014): Phenotypic plasticity of *Rana dalmatina* larvae: ontogenetic variation in anti-predator responses. MSc. thesis, Zoologie, Universität Wien: 37 pp. (in English, with German summary) ["Although anuran larvae are well studied model organisms for phenotypic plasticity in general, little is known about ontogenetic variation in predator induced plastic responses. To conduct an exploratory study on this topic, we performed an outdoor mesocosm experiment, confronting *Rana dalmatina* tadpoles with the presence of dragonfly predators (Aeshnidae) at five different times in their ontogenetic development. The tadpoles which experienced predator presence for the first time one week after the beginning of the experiment (approximately 9-10 days after hatching) showed the strongest plastic morphological responses, as well as retarded growth and delayed time of metamorphosis. The morphological responses were mainly deeper tail fins and a changed body-to-tail-length ratio. As the treatment which experienced predator contact in the second week of the experiment significantly differed from all other treatments and no linear relationship between time spent with predator and plastic responses was found, we can assume that developmental windows and developmental constraints are underlying our findings." (Author)] Address: not stated

14523. Koparde, P.; Mhaske, P.; Patwardhan, A. (2014): New records of dragonflies & damselflies (Insecta: Odonata) from Western Ghats of Maharashtra, India. *Journal of threatened taxa* 6(5): 5744-5754. (in English) ["Odonates were surveyed across 10 localities from Western Ghats of Maharashtra State, India during 2011-2013. We recorded 64 species belonging to 40 genera and 12 families. Seven species are new records for the region, and four out of them (*Heliogomphus promelas*, *Onychogomphus nilgiriensis*, *Protosticta hearseyi*, *Euphaea fraseri*) are new records for Maharashtra State. In this paper, we discuss these species records and their micro-habitats,

and update previous knowledge on distribution of odonates." (Authors)] Address: Koparde, P., Department of Biodiversity, MES's Abasaheb Garware College, Karve Road, Pune, Maharashtra 411004, India

14524. Kosterin, O.E. (2014): Odonata briefly observed on the islands of Bali and Lombok, Lesser Sundas, Indonesia, in the late February 2014. International Dragonfly Fund - Report 74: 1-48. (in English) ["In the second half of February 2014, Odonata were searched for nine days on Bali and four days on Lombok, the western Lesser Sundas, Indonesia. One species, *Orthetrum chrysis* has been for the first time recorded for Bali and six species, *Nososticta emphylla*, *Idionyx murcia*, *Brachydiplax chalybea*, *Agrionoptera insignis*, *Neurothemis ramburii*, *Rhyothemis phyllis* have been for the first time recorded for Lombok. The previous literature concerning the two islands is analysed. To the moment, 55 Odonata species (3 unidentified) are known for Bali and 39 for Lombok, although the actual faunas of both islands are supposed to be equally rich, and further studies on Lombok are necessary. Odonata faunas of Bali and Lombok mirror each other in respect of high shares, 29 and 23%, of Odonata species ranging to the west and east of the two islands, respectively. Efficiency of Lombok Strait as a biogeographical boundary was estimated as high as 0.6, so Wallace Line is of importance for Odonata. Some diagnostic characters of *N. emphylla*, *N. ramburii*, *R. phyllis phyllis* and *Procordulia sambawana* and a taxonomical situation around *Prodasi-neura autumnalis* and *P. humeralis*, which is not justified biogeographically, are discussed. Short notes on habitats and assemblages of Odonata are added." (2014): Isolation and validation of eight microsatellite loci in *Ischnura senegalensis* by pyrosequencing a bead-enriched library. Applied Entomology and Zoology 49: 623-626. (in English) ["Eight microsatellite markers for the population genetics and evolutionary ecology of *I. senegalensis*, which shows body colour polymorphism in females, were developed using a streptavidin-bead enrichment library and pyrosequence by a next generation sequencer. The number of alleles per locus and effective number of alleles ranged from 3 to 11 and from 1.24 to 5.51, respectively. Observed and expected heterozygosities were 0.18–0.75 and 0.19–0.77, respectively. No linkage disequilibrium between loci was detected. One locus, *IsenAC75*, deviated significantly from the Hardy–Weinberg equilibrium, and the locus and additional two loci, *IsenAC40* and *IsenAC8*, were suspected for the presence of null alleles. Altogether, these eight microsatellite loci are considered to be useful for population genetic analyses because of the high polymorphic status and independency." (Authors)] Address: Kurita,

14529. Lorenzo-Carballa, M.O.; Watts, P.C.; Cordero-Rivera, A. (2014): Hybridization between *Calopteryx splendens* and *C. haemorrhoidalis* confirmed by morphological and genetic analyses. *International Journal of Odonatology* 17(2-3): 149-160. (in English) ["Hybridization between *C. haemorrhoidalis* and any of its congeners has not been reported until now. We observed spontaneous matings between male *C. splendens* and female *C. haemorrhoidalis* at a locality in Central Italy, together with some putative hybrid individuals that had a mixed phenotype. Here, we report the morphological and molecular characterization of five suspected hybrids collected from this population during 2001 (n = 1), 2012 (n = 2) and 2013 (n = 2). A discriminant analysis based on 13 morphological variables correctly separated both parental species (with 100% assignment success) and classified the hybrid from 2001 as *splendens* phenotype and those from 2012 and 2013 as *haemorrhoidalis*. Genotype data (microsatellite loci) was used to confirm the hybrid origin of these specimens, although there were differences between the individual from 2001 and those from 2012 and 2013; the 2001 individual had alleles that were present in both parent species, suggesting it is an F1 hybrid, but the individuals collected in 2012 and 2013 had private alleles at eight (out of 12) loci and only a small portion of the genome in common with *C. splendens*, which suggests that introgression is occurring in this population. Similarities in mitochondrial DNA sequences indicate that the 2001 hybrid and the 2012–2013 hybrids have *splendens* and *haemorrhoidalis* maternal origins respectively, which, in contrast with behavioural observations, indicates that interspecific matings in both directions are possible. This is the first demonstration that *C. haemorrhoidalis* can hybridize with other congeners to produce viable offspring." (Authors)] Address: Lorenzo-Carballa, Olalla, Grupo de Ecología Evolutiva e da Conservación, Depto de Ecología e Biología Animal, Univ. de Vigo, EUE Forestal, Campus Universitario A Xunqueira s/n, 36005, Pontevedra, Spain.

14531. Mahdjoub, H.; Khelifa, R.; Zebbsa, R.; Mellal, M.K.; Bouslama, Z.; Houhamdi, M. (2014): Aspects of reproductive biology and ecology of *Coenagrion mercuriale* at its southern range margin. *International Journal of Odonatology* 17(4): 173-180. (in English) ["*Coenagrion mercuriale* is a threatened damselfly in most parts of its geographic distribution. It is listed as endangered in North Africa, where no data on its biology or ecology are available. This study aims to illustrate the reproductive behaviour and habitat preferences of adults in a population located in north-east Algeria, representing the southern limit of the species distribution. After emergence, adults spent 3 to 4 days away from the water to mature. Young mature individuals returned to the stream to mate, sometimes not far from their emergence site. The mean duration of copulation and oviposition were 20.08 ± 8.79 min (\pm SD) and 52.66 ± 12.17 min (\pm SD), respectively, separated by a short post-copulatory rest of 4.60 ± 2.02 min (\pm SD). Copulation duration was positively correlated with male body length while resting duration was positively related to copulation duration. Single males and breeding pairs preferred the same habitats, characterized by relatively dense and high in-channel bank vegetation, and a quite large stream bed, with a substrate which mainly consisted of clay and silt. A comparison of the reproductive behaviour and habitat preferences with a population located in the northern limit of the distribution range is presented and discussed." (Authors)] Address: Mahdjoub, H., Laboratory of Ecology of Terrestrial and Aquatic Systems, Faculty of Sciences, Department of Biology, Badji Mokhtar University, Annaba 23000, Algeria

14533. Malinowska, A.H.; van Strien, A.J.; Verboom, J.;

14534. Malinowska, A.H.; van Strien, A.J.; Verboom, J.; WallisdeVries, M.F.; Opdam, P. (2014): No evidence of the effect of extreme weather events on annual occurrence of four groups of ectothermic species. *PLoS ONE* 9(10): e110219. doi:10.1371/journal.pone.0110219: 10 pp. (in English) ["Weather extremes may have strong effects on biodiversity, as known from theoretical and modelling studies. Predicted negative effects of increased weather variation are found only for a few species, mostly plants and birds in empirical studies. Therefore, we investigated correlations between weather variability and patterns in occupancy, local colonisations and local extinctions (metapopulation metrics) across four groups of ectotherms: Odonata, Orthoptera, Lepidoptera, and Reptilia. We analysed data of 134 species on a 1×1 km-grid base, collected in the last 20 years from the Netherlands, combining standardised data and opportunistic data. We applied dynamic site-occupancy models and used the results as input for analyses of (i) trends in distribution patterns, (ii) the effect of temperature on colonisation and persistence probability, and (iii) the effect of years with extreme weather on all the three metapopulation metrics. All groups, except butterflies, showed more positive than negative trends in metapopulation metrics. We did not find evidence that the probability of colonisation or persistence increases with temperature nor that extreme weather events are reflected in higher extinction risks. We could not prove that weather extremes have visible and consistent negative effects on ectothermic species in temperate northern hemisphere. These findings do not confirm the general prediction that increased weather variability imperils biodiversity. We conclude that weather extremes might not be ecologically relevant for the majority of species. Populations might be buffered against weather variation (e.g. by habitat heterogeneity), or other factors might be masking the effects (e.g. availability and quality of habitat). Consequently, we postulate that weather extremes have less, or different, impact in real world metapopulations than theory and models suggest." 14538. Mehdi, H.; Anwer, S.F.; Ahmad, A. (2014): Vibration analysis of dragonfly wing section in gliding mode at low Reynolds numbers. *International journal of research in aeronautical and mechanical engineering* 2(12): 11-23. (in English) ["The dragonfly wings are highly corrugated, due to light in weight and good corrugation it increases the aerodynamic performance and strength of the wing. When the wings interact with the air, it is subjected to aerodynamic forces acting on the surface of the wing and the inertial force due to the acceleration or deceleration of the wing mass. The interaction between these inertial and aerodynamic forces resulted in wing deformation. We are interesting to calculate deformation and natural frequency of the dragon fly wing at different Reynolds number and different angle of attack. A dragonfly insect has been chosen because MAVs (Micro air Vehicles) and Dragonfly works almost same Reynolds Number i.e. Re- 102 to 104. In this work, Numerical study of Vibration Analysis for a Pleated Insect 2D Airfoil at Ultra Low Reynolds Numbers is carried out in gliding mode. The dynamics of a pleated insect wing

subjected to aerodynamic loading is studied for different Reynolds Number ranging from 100 to 1000 at different angle of attack ranging from 00 to 150 by using ANSYS-14 multi physics solver. The result from the CFD solver will be fed in the form of lift and drag forces are then fed into the ANSYS Workbench solver and vibration analysis is performed." 14539. Meng, L.-b.; Ang, H.-s.; Xiao, T.-h. (2014): Analysis of aerodynamic characteristics of flexible wing of dragonfly based on CFD/CSD method. *Journal of Aerospace Power* 29(9): 2063-2069. (in Chinese, with English summary) ["A methodology of fluid-structure bi-directional interaction based on computational fluid dynamics/computational structure dynamics (CFD/CSD) was presented. The donor-receptor relationship between two sets of grid system was identified by alternating digital tree (ADT). The local interpolation methods were used for data exchange between these two sets of grids. Flow with moving boundaries was dealt with by Delaunay graph mapping method. The code for nonlinear structural finite element and information transfer was developed and used to connect with the code of flow solver 3D2 MUFS developed in the Micro Air Vehicle Center of Nanjing University of Aeronautics and Astronautics (NUAA). It was applied to the aerodynamic computation of dragonfly flapping flight with flexible wing. Results show that the time-averaged vertical force coefficient of the dragonfly wing increases from 0.31 to 0.53, and the time-averaged thrust coefficient increases from 0.07 to 0.13 by flexible deformation. This confirms that the flexible deformation can improve the aerodynamic performance of flapping wing." 14541. Nagel, L.; Mlynarek, J.J.; Forbes, M.R. (2014): Comparing natural parasitism and resistance with proxies of host immune response in lepid damselflies. *Ecological Parasitology and Immunology* 3 (2014), Article ID 235884, doi:10.4303/epi/235884: 7 pp. (in English) ["Commonly used proxies for measuring immune responses in invertebrates include the amount of melanin deposited on nylon inserts and assays of activity of the enzyme phenoloxidase (PO) in the haemolymph. We used these proxies to estimate immunity in unparasitized individuals from four Lepid damselfly species (*L. disjunctus*, *L. congener*, *L.*

rectangularis, *L. forcipatus*) from populations with different levels of water mite parasitism. Levels of parasitism and resistance by hosts were population level estimates from published papers. These parasitism levels were not correlated positively with immune response measured by proxies in the current study. The species with the strongest melanization response to the inserts and the highest PO levels was the one that currently experienced no mite parasitism. The species with the weakest response to the inserts and the lowest PO levels had low current levels of parasitism. The two species that are heavily parasitized had an intermediate response. Natural resistance levels were also not correlated with the response measured by proxies, but the species with a strong response had high levels of resistance in the past. This finding is supported by earlier work done with Lepidoptera in which the most well-defended species currently experience no natural parasitism." 14542. Naidu, V.; Young, J.; Lai, J. (2014): Effect of wing flexibility on dragonfly hover flight. 19th Australasian Fluid Mechanics Conference, Melbourne, Australia, 8-11 December 2014: 4 pp. (in English) ["The role of wing flexibility in tandem wings during the hover flight at phase 180. was investigated using Fluid Structure Interaction (FSI) simulations. The wing shapes were that of the dragonfly species *Aeshna juncea* and the flexible wing models displayed wing stiffnesses as found in the real wings. Wing flexibility enhanced the lift generated by both the tandem wings, with the forewing and the hindwing generating 10% and 17% more lift respectively, as compared to the rigid wings." 14543. Naka, H.; Sunami, Y.; Hashimoto, H. (2014): Development of the artificial wing suitable for flapping Micro Air Vehicle based on dragonfly wing. The 3rd International Conference on Design Engineering and Science, ICDES 2014 Pilsen, Czech Republic, September 1-3, 2014: 78-83. (in English) ["The dragonfly wing is passively deformed under flapping and has the strength to withstand high flapping frequency simultaneously. These characteristics of deformation and vibration of the wing is important for dragonfly flight. However, the effect of those on dragonfly flight has not been well understood. The purpose of this study is to develop an artificial wing suitable for flapping Micro Air Vehicle on the basis of the dragonfly wing. Therefore, natural frequency and deformation of the dragonfly wing are measured, and the artificial wing is fabricated on the basis of result of that. From the results of measurement, the dragonfly wing has the high natural frequency of 120 Hz. Although base-side of the wing is hardly deformed, the tip-side of the wing is greatly deformed because of the torsional deformation from the nodus of dragonfly wing. Then, the deformable artificial wing which can deform in the same manner of dragonfly wings was fabricated, and

aerodynamic force and power consumption under flapping was measured. As a result, the power efficiency of aerodynamic force using the deformable artificial wing is 5 times greater than the power efficiency using an undeformable wing." 14544. Nasiruddin, M.; Azadi, M.A.; Reza, M.S. (2014): Abundance and diversity of aquatic insects in two water bodies of Chittagong university campus. *Bangladesh J. Zool.* 42(1): 19-33. (in English) ["Abundance and diversity of aquatic insects was studied in two water bodies, (a pond and a lake) of Chittagong University campus during October 2009 to September 2010. A total of 4406 insects belonging to 32 genera, under 20 families and 6 orders were recorded. In both the water bodies, the representatives of the orders Hemiptera and Odonata (identified using a North American key) were the most abundant groups. During the study period highest abundance of the total insects was recorded in November 2009 and the lowest in July 2010. Abundance of insects was comparatively higher in the pond habitat than in the lake. The Quotient of Similarity (QS) of the insects between the two water bodies was found to be the highest in October 2009 and lowest in July 2010. Species diversity, species richness and species evenness values of the lake were higher than that of the pond. *Hydrophilus* sp. and *Sphaerodema* sp. were the most dominant insects in the pond, while *Chironomus* sp. and *Gerris* sp. in the lake." (Authors)] Address: Nasiruddin, Munira, Dept of Zoology, University of Chittagong, Chittagong 4331, Bangladesh. E-mail: maazadi@yahoo.com

14545. Nelson, M. (2014): Surveying Odonata: are current monitoring methods up to the task? *J. Br. Dragonfly Society* 30(1): 17-31. (in English) ["Surveying odonates has focused historically on adult populations which are visible and amenable to standard types of surveying but recent work has suggested this may be giving a biased result, with consequent impact on conservation decision making and management. This study attempts to investigate whether there is a difference in results of larval and adult surveys and whether any difference found is specific to type of habitat or particular species." 14546. Nelson, S.J.; Chen, C.; Kahl, J.S.; Krabbenhoft, D.P. (2014): Validating landscape models for mercury in northeast lakes using dragonfly nymphs as mercury bio-sentinels. University of Maine Office of Research and Sponsored Programs: Grant Reports. Paper 52. <http://digitalcommons.library.umaine.edu/orspreports/52>: 32 pp. (in English) ["Mercury (Hg) is a toxic pollutant that is widespread in northeastern US ecosystems. Resource managers' efforts to develop fish consumption advisories for humans and to focus conservation efforts for fish-eating wildlife are hampered by significant variability in fish Hg

concentrations from site to site - often in neighbouring lakes. Watershed characteristics that vary across the Northeast such as forest type and wetlands are important predictors of methylation. Although data syntheses leading to hotspot maps (e.g., Evers et al. 2007) and sensitivity modelling have been conducted (Krabbenhoft et al. 2011), we still lack studies that use sentinel biota and have statistically rigorous sampling designs across the broad region. Fish Hg concentrations are most often used as biological indicators of Hg sensitivity in lakes; however, fish may move between waterbodies and interpretation can be confounded by size, species, diet, gender, and age. This project sampled lake water and a biosentinel, dragonfly larvae, in a statistical sample of 74 lakes that are part of US EPA long-term monitoring across the region to (1) test models for prediction of Hg and MeHg in water, and (2) determine the efficacy of this bio-sentinel in predicting sensitivity to Hg across the region. In the Upper Midwest, MeHg in dragonfly larvae was significantly, positively correlated with THg in perch (Knights et al. 2005) and researchers concluded that dragonfly larvae were promising bio-sentinels in that region (Haro et al. 2013). We hypothesized that dragonfly larvae are good indicators of Hg spatial patterns because they are widespread in fresh waters across this region, long-lived (1-5 years or more), exhibit site fidelity, are carnivorous, contain almost all of their Hg as MeHg, and have relatively high Hg concentrations. The project leveraged ongoing research at a statistical sample of 74 lakes across New England states and New York, sampled annually by cooperators in the US Environmental Protection Agency (EPA) Long-Term Monitoring (LTM) Network." 14547. Neves, M.; Morais, C.S.; Garda, A.A. (2014): Sexual dimorphism and diet of *Pseudis tocantins* (Anura, Hylidae, Pseudidae). *South American Journal of Herpetology* 9(3): 177-182. (in English) ["The genus *Pseudis* (Hylidae) includes aquatic frogs distributed throughout South America east of the Andes. Few papers have been published on the ecology of these species, despite the great interest their gigantic larvae raise among herpetologists. *Pseudis tocantins* has a widespread distribution along the Tocantins-Araguaia hydrographic basin in Brazil and virtually nothing has been published about its natural history and ecology. The present work aimed to evaluate, based on 159 specimens from 13 populations, sexual dimorphism in size and shape and diet composition of *P. tocantins* along most of its known distribution. Females were significantly larger than males and body shape differed significantly between sexes, with tibia length and tympanum diameter as the variables contributing the most to this difference. We found 13 prey categories in frog's stomachs, with Araneae, Odonata, and Orthoptera being the most important items, respectively. Aquatic animals were also part of the species diet (even though less representative than

non-aquatic prey), showing that *P. tocantins* feeds on both above water and subaquatic prey." (Authors)] Address: Neves, M., Departamento de Biologia Animal, Universidade Federal de Viçosa. Avenida Peter Henry Rolfs s/n, CEP 36571 -000, Viçosa, MG, Brazil. E-mail: pseudis@gmail.com

14548. New, T.R.; Samways, M.J. (2014): Insect conservation in the southern temperate zones: an overview. *Australian Journal of Entomology* 53(1): 26-31. (in English) ["Insect conservation in the southern hemisphere lags substantially behind developments in parts of Europe and North America, where the relatively small faunas are better documented, and where a historical culture of natural history has enabled conservation needs to be assessed and addressed by many sympathetic supporters. We contrast this scenario with the much more embryonic knowledge and capability available in Australia, southern Africa, southern South America and New Zealand, all regions with large and incompletely documented insect faunas, but an equivalent array of threats to their survival. While a few individual 'flagship species' (mainly within Lepidoptera, Orthoptera and Coleoptera) have been critical in promoting wider interests, in general insects do not signify highly on regional conservation agendas. We offer a perspective of the major needs to counter this... Dragonflies are also relatively well studied. They have been surveyed comprehensively through the Odonata Database of Africa and the World Conservation Union's (IUCN) Species Survival Commission's Africa Freshwater Assessment (Clausnitzer et al. 2012). A comprehensive assessment of Argentinian dragonflies has begun, as part of an initiative to increase awareness of insect conservation in the country, discussed in detail at the 2012 meeting of the Entomological Society of Argentina." 14549. Nguyen, S.H.; Webb, H.K.; Hasan, J.; Tobin, M.J.; Mainwaring, D.E.; Mahon, P.J.; Marchant, R.; Crawford, R.J.; Ivanova, E.P. (2014): Wing wettability of Odonata species as a function of quantity of epicuticular waxes. *Vibrational Spectroscopy* 75: 173-177. (in English) ["Dragonflies have gained much attention due to their sophisticated wing surface structure, and their associated superhydrophobic, self-cleaning and bactericidal properties. In this work, we compared and contrasted the chemical composition and surface morphology of the wing membranes of four species of dragonfly and damselfly from the Odonata family collected in 1970s (*Diplacodes melanopsis* and *Xanthagrion erythroneurum*) and 2011 (*Diplacodes bipunctata*, and *Ischnura heterosticta*). .. Fourier-transform infrared spectroscopy data obtained from the Australian Synchrotron were used to classify the fundamental components of all four of the insect species' wings. The spectra of all species were dominated by C-H stretching, Amide I and Amide II and O-H stretch absorbance indicating similar membrane composition of chitin,

protein and wax in all four species. Although the samples were collected 40 years apart, there was no evidence of degradation during this time. Despite the overall similarities in spectral profile, species-specific differences were observed, most notably the intensity of the vCH₂ peaks, which in part reflect the amount of waxes present on the wings, appeared different between species. The surface topography also contained minor differences in their pillar diameter and spatial distribution. It is postulated that the differences in surface wettability of the wings could be attributed to these minor differences in surface chemistry and surface topography. For example, *X. erythroneurum* presented the highest water contact angle (WCA) of 160° whilst the *D. melanopsis* wings exhibited the lowest WCA (138°). And the wettability of their wings was found to directly correlate with the intensity of hydrocarbon peaks found in their respective IR spectrum." 14553. Olberg, R.M ; Gonzalez-Bellido, P.; Wardill, T. (2014): The neuronal control of flying prey interception in dragonflies. Final rept. 15 May 2010-14 May 2014: 18 pp. (in English) ["Eight pairs of large descending visual neurons (TSDNs) control dragonfly prey interception flights. We investigated both the sensory inputs and the motor outputs of this group of neurons. A detailed map was obtained of the position and direction of target movement that excites each of the TSDNs. This study also revealed the anatomy of the TSDN output terminals, providing information about the likely pattern of connectivity from individual TSDNs to the neural circuitry controlling each of the wings. Angular speed is also encoded by the TSDNs. This speed sensitivity increases the gain of the system as the dragonfly approaches its prey. Distance appears not to be encoded by the TSDNs when the head is fixed. However binocular inputs are required for maximal responses. The functional implication of the binocular inputs is not yet known. Intracellular electrical stimulation of individual TSDNs confirmed their role in adjusting wing position and angle. TSDN activity rotates the head as well in the direction opposite the preferred target direction. Two TSDNs also move the legs and mouthparts." 14554. Olomukoro, J.O.; Dirisu, A.-R. (2014): Status and the diversity of macrobenthos of Udu - Ghievwen wetlands in the Niger delta, Nigeria. Journal of natural science research 4(18): 6 pp. (in English) ["A survey on the status and diversity of benthic fauna community of Udu – Ughievwen wetlands was carried out for a period of six months. Benthic samples were collected using the Ekman Grab made by Hydrobios. Water Hyacinth (*Eichornia crassipes*) was also sampled for benthic organisms. A total of twelve taxonomic groups were recorded in this study and they include; Ephemeroptera (37.63%), Diptera (20.45%),

Decapoda (14.39%), Odonata (6.48%), Annelida (5.97%), Coleopterans (4.21%) and Trichoptera (3.87%). Others were; Mollusca (3.45%), Amphibian (2.85%), Hemiptera (2.27%) and Arachnida (0.42%). The highest number of individuals was collected from Ohwawha (171) and least at Ofri (60). Shannon – Weiner diversity (H) was highest at Ujevuu and least at Ofri sampling stations respectively. The suitability and diversity of the macrohabitats in the various study sites have favoured the abundance of benthic macroinvertebrates particularly the Decapoda, Ephemeroptera, and Diptera in these water bodies. The dominance of Ephemeroptera in most of the sites indicates a healthy nature or sound environmental quality of the entire Udu – Ughievwen wetlands. The study revealed that wetlands are populated by a rather different assortment of macroinvertebrates." (Authors) Taxa are detailed at genus level, but obviously were identified using a key from North America.] Address: Olomukoro, J.O., Dept of Animal & Environmental Biology, Faculty of Life Sciences, University of Benin, Benin City, P.M.B. 1154, Nigeria

14557. Outomuro, D.; Söderquist, L.; Rodríguez-Martínez, S.; Johansson, F. (2014): A preliminary study on female-limited colour polymorphism in *Lestes sponsa*. International Journal of Odonatology 17(2-3): 89-93. (in English)

["Female-limited colour polymorphisms are widespread in Odonata, usually showing an androchrome and one or more gynochromes. Androchromes have been hypothesized to function as male mimics with a consequent decrease of male harassment, although males may also learn to recognize the different female colour morphs. In the Eurasian damselfly *Lestes sponsa*, the occurrence of two female colour morphs (androchrome and gynochrome) has been known since the beginning of the twentieth century, although this has been generally overlooked. In this work, we studied a Swedish population of *L. sponsa* by counting the number of females of each morph during nine consecutive days, as well as the number of tandems. Androchromes showed blue pruinescence at similar body parts as males, although more limited at the tip of the abdomen. Moreover, androchromes also showed bright blue coloured eyes as males. We found no indication that androchromes might be a result of age changes in female coloration. The androchrome morph accounted for 19% of the female population. Androchromes did not form tandems at a lower frequency than expected in the population, given the frequency of presence of each morph. Therefore our results suggest that either androchromes in this species do not function as male mimics, or that the population has reached equilibrium with equal fitness for each morph. Other aspects of male harassment and learned mate-recognition, as well as female morph behaviour, would shed light on the evolutionary and ecological significance of female morphs in this species." 14558. Pal, P.; Roy, S. (2014): Edible insects: Future of human food - a review. *International Letters of Natural Sciences* 21: 1-11. (in English) ["The practice of eating insects is known as entomophagy. ... People throughout the world have been eating insects as a regular part of their diets for millennia. As people in rural areas suffer from under nutrition, especially protein-energy malnutrition (PEM) in Africa, Latin America and Asia, alternative nutritional food sources are needed. From ants to beetle larvae – eaten by tribes in Africa and Australia as part of their subsistence diets – to the popular, crispy-fried locusts and beetles enjoyed in Thailand, it is estimated that insect-eating is practised regularly by at least 2 billion people worldwide. More than 1900 insect species have been documented in literature as edible, most of them in tropical countries. The most commonly eaten insect groups are beetles, caterpillars, bees, wasps, ants, grasshoppers, locusts, crickets, cicadas, leaf and plant hoppers, scale insects and true bugs, termites, dragonflies and flies. The purpose of the present review is to determine the status of present research in the context of the potentiality of insects as alternative food source to cope up with the emerging problem of global food crisis. .. Dragonflies including *Anax guttatus* and *Trithemis arteriosa* are collected in paddy fields in the DRC (Malaisse, 1997), the Philippines, north and northeast

Thailand (Pemberton, 1995), and China (Feng et al., 2001). Nymphs are often stir-fried or boiled before eating." (Authors)] Address: Pal, P., Department of Zoology, Scottish Church College, 1 & 3 Urquhart Square, Kolkata - 700006, India. E-mail: parthapal_iicb@yahoo.co.in

14559. Palacino-Rodríguez, F.; González-Soriano, E.; Sarmiento, C.E. (2014): Phylogenetic signal of subsets of morphological characters: a case study in the genus *Erythemis* (Anisoptera: Libellulidae). *Caldasia* 36(1): 85-106. (in English, with Spanish summary) ["*Erythemis* Hagen, 1861 shows a considerable variation in genitalic characters, body coloration and wing venation. Since it is known that these traits are affected by different kinds of selection that probably blur their phylogenetic signal, we chose the genus *Erythemis* as a model taxon to analyze and compare the phylogenetic signal of these and other morphologic characters. A cladistic analysis was performed using ten species of the genus plus another seventeen species of Libellulidae as outgroup. Characters were defined following standard criteria and were managed using the software DELTA. Tree search was performed with the software NONA. Partitioned and combined analyses were conducted. Character tracking of characters with $ri=100$ was used to identify synapomorphies. In agreement with the literature, color characters provided strong phylogenetic signal, meanwhile, genitalia characters offered no synapomorphies. We did not find any character that could support the monophyly of *Erythemis*. The only clade that has strong support from the morphologic set of characters is (*E. vesiculosa*, (*E. simplicicollis*, *E. collocata*)). Contrary to the results found in other Odonata, wing characters offered synapomorphies for some *Erythemis* clades." In May 2014 a breeding population was observed in southern Tenerife, Spain, at a freshwater reservoir near Las Galletas. Characters are provided for discriminating between the two known *Ischnura* species

on the islands, *I. senegalensis* and *I. saharensis*, from photographs." (Author)] Address: Peels, F., Via Caffarini 41, 53100 Siena, Italy. E-mail: info@dragonflypix.com

14562. Perroy, R.L.; Belby, C.S.; Mertens, C.J. (2014): Mapping and modeling three dimensional lead contamination in the wetland sediments of a former trap-shooting range. *Science of The Total Environment* 487: 72-81. (in English) ["Highlights: •We mapped 3D Lead contamination in the wetland sediments at a former shooting range. •X-ray fluorescence & imaging allow rapid and inexpensive quantification of contamination. •Highest Pb contamination levels were typically found 10-30 cm below sediment surface. •We report high-resolution volumetric contamination estimates at various action levels. •Our mapping and modelling techniques can be readily applied to other contaminated sites. Abstract: Legacy lead (Pb) contamination from sport shooting activities is a well-known hazard. Assessing the risk this contamination presents to the environment and public health requires a detailed understanding of its spatial distribution, yet our knowledge in this area is limited, especially for wetland shooting ranges. In this study, we analyzed 1351 sediment samples from 456 surficial (0–5 cm) locations and 38 sediment cores (0.3 to 0.9 m) to quantify the three dimensional spatial distribution of Pb contamination in an urban wetland at the site of a former trap shooting range located in southwestern Wisconsin, USA. Non-destructive X-ray images of the sediment cores were used to quantify Pb shot abundance and burial depth. Surficial and core sediment samples were processed and analyzed for total Pb content via X-ray fluorescence (XRF) analysis. X-ray and XRF results were interpolated to create a three-dimensional model of Pb shot density and sediment concentration across the study area. Over 31,000 m³ of sediment surpassed the US Environmental Protection Agency's contamination threshold of 400 mg/kg Pb, with a maximum calibrated value of 26,700 mg/kg Pb occurring near the center of the expected shot fallout zone. Shot densities of > 50,000 pellets/m² were found in the shot fallout zone, primarily 10–30 cm below the sediment surface. X-ray image analysis and XRF analysis of sediment cores provide an accurate and inexpensive technique for rapidly mapping Pb contamination associated with gun clubs and hunting; these findings will benefit environmental contamination studies and remediation efforts at active and abandoned shooting ranges worldwide. ... Supernumerary antenna malformations in Corduliidae (dragonfly) specimens 135 collected within the LRM shot fallout zone were also observed prior to 136 this study, and hypothesized to be linked to high Pb exposure (R. Haro, UW - La Crosse Biology Department, pers. com)."] (Authors)] Address: Perroy, R.L., Dept of Geogr. & Environ.I Sci., Univ. of Hawaii at Hilo, 200W. Kawili Street, Hilo, HI 96720-4091, USA. 14564. Petzold, F.; Fritzlar, F. (2014): Basiserfassungen zur Libellenfauna – Landesweites Probestellennetz für ein Libellenmonitoring in Thüringen. *Landschaftspflege und Naturschutz in Thüringen* 51(1): 3-11. (in German, with English summary) ["The state of Thuringia (Germany) built up a large stock of dragonfly-data set in cooperation with the voluntary working group which explore Thuringian dragonflies. This set of data is to be supplemented by an equably distributed and standardized state wide grid of study areas. The aim of this new established monitoring program is to get more precise information about the change of dragonfly inventory in future. The project concentrates on dragonfly habitats with local importance. Between 2010 and 2012, 44 large scale maps in five rural districts get researched. In the analysed 220 water bodies 51 dragonfly species were recorded - 78 percent of the state wide known species. 15 of this species are recorded at the Thuringian Red List. *Coenagrion mercuriale*, *Leucorrhinia pectoralis*, *Sympetrum meridionale*, and *Sympetrum pedemontanum* are endangered or extreme rare. To protect the dragonfly biodiversity, the most valuable water bodies have to be conserved and deficits of the water body conditions have to be eliminated." 14565. Pham, T.T.; Higgins, C.M. (2014): A visual motion detecting module for dragonfly-controlled robots. *Engineering in Medicine and Biology Society (EMBC), 2014 36th Annual International Conference of the IEEE*, 26-30 Aug. 2014: 1666-1669. (in English) ["When imitating biological sensors, we have not completely understood the early processing of the input to reproduce artificially. Building hybrid systems with both artificial and real biological components is a promising solution. For example, when a dragonfly is used as a living sensor, the early processing of visual information is performed fully in the brain of the dragonfly. The only significant remaining tasks are recording and processing neural signals in software and/or hardware. Based on existing works which focused on record-

ing neural signals, this paper proposes a software application of neural information processing to design a visual processing module for dragonfly hybrid bio-robots. After a neural signal is recorded in real-time, the action potentials can be detected and matched with predefined templates to detect when and which descending neurons fire. The output of the proposed system will be used to control other parts of the robot platform."(Authors) For details see: http://thehigginslab.webhost.uits.arizona.edu/pubs/2011-_thuy_pham_thesis.pdf Address: Pham, Thuy T. ; Dept of Electrical and Computer Engineering and Department of Neuroscience, University of Arizona, AZ USA 85716

14567. Pospekhova, N.A.; Regel, K.V.; Gulyaev, V.D. (2014): Ultrastructural study of protective envelopes in *Dioecocestus asper* (Cestoda: Dioecocestidae) megalocercus. *Parazitologiya* 48(2): 89-96. (in English, with Russian summary) ["The megalocercus of *Dioecocestus asper* (Mehlis 1831) from the haemocoel of dragonfly larvae possesses two envelopes: outer (exocyst) and inner (endocyst) ones. The exocyst contains the large endocyst and larval strobila with scolex attached to the latter. Outer and inner surfaces of these envelopes are organized as the tegument and have some structural differences. The exocyst is covered with slender microvilli. Its outer tegument contains numerous mitochondria; the inner one is filled with lipid droplets released into the exocyst's cavity. The well-developed protonephridial (excretory) system consisting of flame cells, collecting ducts and canals is the unique feature of the exocyst, noted for the first time. Thick (more, than 50 microm) distal cytoplasm of the outer tegument of the endocyst is the place of accumulation of uniform globules looking like a hyaloid layer. This outer layer together with underlying fibrous layer (up to 20 microm), apparently, protect the scolex and larval strobila during the transfer through feather clump in the stomach of grebes, definitive hosts of *D. asper*. Muscle cells of both envelopes retain their synthetic activity even in the fully developed metacestode. Probably, they are the main structural element, which produces fibers of the extracellular matrix and maintains the integrity of protective envelopes of the megalocercus." (Authors) The original material was obtained by dissection of dragonfly larvae of the genus *Aeshna* from lakes of the Upper Kolyma basin.] Address: Pospekhova, Natalia, Institute of Biological Problems of the North FEB RAS Magadan, 685000, Russia. 14568. Post, M. (2014): Die Libellenfauna im Raum Neustadt 2013. *Pollichia-Kurier* 30(1): 20-22. (in German) [The

author summarizes the regional Odonata records in the Neustadt-region (Rheinland-Pfalz, Germany) for the year 2013. Due to a long and cold winter the phenology of many species was shifted. Interesting is that the so-called climate change winners were not harmed by this winter, and partly even expanded their local/regional range due to optimal habitat availability. The situation for some formerly very frequent species as *Lestes sponsa* and *Sympetrum vulgatum* seems to be dramatic. *S. flaveolum* and *S. depressiusculum* are believed to be abandoned the site because they have not been observed in the past years. *Ophiogomphus cecilia* was observed latest on 3-XI-2013] Address: Post, M. E-mail: libellen-nw@web.de

14569. Rasmussen, N.L.; Van Allen, B.G.; Rudolf, V.H.W. (2014): Linking phenological shifts to species interactions through size-mediated priority effects. *Journal of Animal Ecology* 83(5): 1206-1215. (in English) ["(1.) Inter-annual variation in seasonal weather patterns causes shifts in the relative timing of phenological events of species within communities, but we currently lack a mechanistic understanding of how these phenological shifts affect species interactions. Identifying these mechanisms is critical to predicting how inter-annual variation affects populations and communities. (2.) Species' phenologies, particularly the timing of offspring arrival, play an important role in the annual cycles of community assembly. We hypothesize that shifts in relative arrival of offspring can alter interspecific interactions through a mechanism called size-mediated priority effects (SMPE), in which individuals that arrive earlier can grow to achieve a body size advantage over those that arrive later. (3.) In this study, we used an experimental approach to isolate and quantify the importance of SMPE for species interactions. Specifically, we simulated shifts in relative arrival of the nymphs of two dragonfly species (*Pantala flavescens*, *Tamea carolina*) to determine the consequences for their interactions as intraguild predators. (4.) We found that shifts in relative arrival altered not only predation strength but also the nature of predator-prey interactions. When arrival differences were great, SMPE allowed the early arriver to prey intensely upon the late arriver, causing exclusion of the late arriver from nearly all habitats. As arrival differences decreased, the early arriver's size advantage also decreased. When arrival differences were smallest, there was mutual predation, and the two species coexisted in similar abundances across habitats. Importantly, we also found a nonlinear scaling relationship between shifts in relative arrival and predation strength. Specifically, small shifts in relative arrival caused large changes in predation strength while subsequent changes had relatively minor effects. (5.) These results demonstrate that SMPE can alter not only the outcome of interactions but also the demographic rates of species and the structure of communities. Elucidating the mechanisms that link phenological shifts to species interactions is crucial for understanding the dynamics of seasonal communities as well as for predicting the effects of climate change on these communities." 14571. Riservato, E.; Fabbri, R.; Festi, A.; Grieco, C.; Hardersen, S.; Landi, F.; Utzeri, C.; Rondinini, C.; Battistoni A.; Teofili C. (com.) (2014): Lista Rossa IUCN delle libellule Italiane. Comitato Italiano IUCN e Ministero dell'Ambiente e della Tutela del Territorio e del Mare, Roma: 39 pp. (in Italian, with English summary) ["The main objectives of this research are: 1) the creation of an expert network for the evaluation of the extinction risk of dragonflies and damselflies in Italy; 2) the evaluation of the extinction risk for all Italian dragonflies and damselflies; 3) the creation of a baseline for future evaluations of the trends in biodiversity conservation in Italy. The assessments of extinction risk are based on the IUCN Red List Categories and Criteria and the most up-to-date guidelines. The assessments have been carried out in a workshop involving experts covering different taxa and regions in Italy, and have been evaluated according to the IUCN standards. All dragonflies and damselflies native or possibly native to Italy have been included in the evaluation. In all cases the entire national population has been evaluated, including large and small islands where necessary. Of the 93 species assessed, one has become Regionally Extinct in recent times. Threatened species total 10, corresponding to 10.9% of the species assessed. Ca. 72% of the species are not currently threatened with extinction. Overall the populations of Italian dragonflies and damselflies are declining, as species in decline outnumber species in expansion by 5 to 1. The main threats are habitat loss and pollution. Threatened species, as well as species experiencing population declines, concentrate in natural freshwater wetlands. The Red List is a fundamental tool for the identification of conservation priorities, but it is not a list of priorities on its own. Other elements instrumental to priority setting include the cost of action, the probability of success, and the proportion of the global population of each species living in Italy, which determines the national responsibility in the long term conservation of that species." 14573. Roberts, D. (2014): Rapid habituation by mosquito larvae to predator kairomones. *Journal of Vector Ecology* 39(2): 355-360. (in English) ["Larvae of some species of mosquitoes have been shown to respond to water-borne kairomones from predators by reducing bottom-feeding and replacing it with surface filter-feeding, which uses less movement and is thus less likely to attract a predator. However, if no predator attack takes place, then it would be more efficient to use a risk allocation strategy of habituating their response depending on the predator and the overall risk. The larvae of *Culiseta longiareolata* Macquart live in temporary rain-filled pools, where they are exposed to a high level of predation. Within one hour, they responded to kairomones from dragonfly or damselfly nymphs, or to the fish *Aphanius*, by significantly reducing bottom-feeding activity. Continued exposure to the predator kairomones resulted in habituation of their response to damselflies, a slower habituation to fish, but no habituation to dragonflies even after 30 h. In contrast, the larvae of *Culex quinquefasciatus* Say normally live in highly polluted and thus anaerobic water, where the predation risk will be much lower. They also showed a significant reduction in bottom-feeding after 1 h of exposure to predator kairomones but had completely habituated this response within 6 h of continuous exposure. Some species of mosquito larvae can thus show a very rapid habituation to predator kairomones, while others only habituate slowly depending on the predator and overall predation risk." 14575. Roland, H.-J.; Stübing, S. (2014): *Sympetrum meridionale* in Deutschland – langfristige Bestandsentwicklung und aktuelle Vorkommen (Odonata: Libellulidae). *Libellula* 33(1/2): 75-98. (in German, with English summary) ["Long-term development and current occurrence of *Sympetrum meridionale* in Germany (Odonata: Libellulidae) – Based on ca 700 field records and data from the literature, the occurrence and distribution of *Sympetrum meridionale* in Germany is compiled and analyzed over four periods between 1890 and 2013. While the species was only sporadically and locally recorded until the turn of the millennium, it clearly dispersed to east and north thereafter. Up to 2013 it was found in all federal states of Germany except Schleswig-Holstein and the city states Bremen and Berlin. In 7 of 13 federal states the species was only observed from 2006 onwards. Presumably the species dispersed northwards along the Rhine valley and immigrated from France, Belgium and the Netherlands to North Rhine-Westphalia. For records in eastern Germany, there are no distinct explanations so far. Both, immigration from Hungary and also from the west seems possible. As invasions in single years could not be ascertained, slow dispersal in Germany with temporary reproduction seems more likely. Perennial colonization was only found in a few regions. Presumably, this dispersal cannot only be explained by improved identification methods and increased attention to this species. For reproduction *S. meridionale* needs shallow water bodies with low water-level for oviposition and flooding during the subsequent months until emergence in the following year. Despite creation of numerous ponds as a result of conservation measures, shallow water bodies with periodically oscillating water levels are still rare, but increasing in number. The continuous high number of annual summer days since the year 2000 may support the dispersal trend." (Authors)] Address: Roland, H.-J., Im Mühlahl 35, 61203 Reichelsheim, Germany. 14576. Roland, H.-J.; Hein, A.T.; Martens, A.; Wildermuth, H. (2014): *Sympetrum meridionale* mit Milbenbefall an den Flügeln: Analyse der Funde im Jahr 2013 in Deutschland (Acari: Hydrachnidia; Odonata: Libellulidae). *Libellula* 33(1/2): 99-108. (in German, with English summary) ["Water mites on the wings of *Sympetrum meridionale*: an analysis of the 2013 records in Germany (Acari: Hydrachnidia; Odonata: Libellulidae) – During an extensive survey of *Sympetrum meridionale* in Germany parasitism of this species by the water mite *Arrenurus papillator* was recorded on the basis of photographic documents. The localities of parasitised dragonfly imagines were distributed north to Lower Saxony and Brandenburg and included all federal states with records of *S. meridionale*. Most records

originated from Hesse and Rhineland-Palatinate, both states featured the greatest density of locations and highest number of individuals per locality. A total of 29 parasitised dragonflies were found, 28 thereof bore 1-4 mites on the wings, thus the rate of parasitism and parasite load were low. In addition and for the first time recorded, on one young male at least two mite larvae were attached on the ventral side of the thorax. As *S. meridionale* emerged in 2013 at several German localities the mites presumably originated from there." (Authors)] Address: Roland, H.-J., Im Mühlahl 35, 61203 Reichelsheim, Germany. E-mail: hjroland@gmx.de

14577. Rosset, V.; Angélibert, S.; Arthaud, F.; Bornette, G.; Robin, J.; Wezel, A.; Vallod, D.; Oertli, B. (2014): Is eutrophication really a major impairment for small waterbody biodiversity? *Journal of Applied Ecology* 51(2): 415-425. (in English) [Switzerland; "(1) Eutrophication remains a major stress for freshwater biodiversity. Its deleterious consequences on biodiversity are well-documented for large waterbodies. However, the impact of eutrophication may differ in smaller waterbodies, such as ponds and small lakes, which generally support naturally high levels of nutrients in lowlands. Furthermore, this response could depend on the scale considered, from local (individual waterbody, alpha diversity) to regional (the network of waterbodies, gamma diversity). It is also unclear if the richness of threatened species responds in the same way as the richness of the whole assemblage. (2) The present study investigates local- and regional-scale consequences of eutrophication on taxonomic richness (all taxa) and conservation value (threatened taxa) in temperate lowland small waterbodies. Five taxonomic groups were investigated: macrophytes, gastropods, water beetles, adult dragonflies and amphibians, in a set of natural waterbodies and a set of enriched waterbodies covering a large nutrient gradient from mesotrophic to hypertrophic conditions. (3) Globally, our study did not reveal consistent, systematic responses to eutrophication. For macrophytes, the richness and conservation value suffered from eutrophication at both local and regional scales. In contrast, for amphibians and gastropods, eutrophication did not impair biodiversity at the local nor the regional scale. Dragonflies and water beetles showed intermediate situations, with an impairment by eutrophication varying according to the type of waterbodies considered. At the regional scale, each trophic status, even the nutrient-richest, brought an original contribution to biodiversity. (4) Synthesis and applications. The management of eutrophication for small lowland waterbodies has to be considered differently than for lakes. For an individual waterbody (the local scale), nutrient enrichment is not necessarily a major impairment and its impact depends on the taxonomic group considered. Conversely, at the landscape scale, eutrophication is a major pressure on small waterbody biodiversity, especially because nutrient-rich small waterbodies are dominant in the landscape. Therefore, conservation efforts should integrate the notion of pond regional networks or "pondscapes", where the regional biodiversity is supported by a mosaic of trophic conditions, and promote the presence of less-rich

waterbodies." (Authors)] Address: Rosset, Veronique, Univ. of Applied Sciences Western Switzerland, hepia Geneva Technology, Architecture & Landscape, Jussy, Geneva, Switzerland. E-mails: veronique@rosset.org

14578. Saha, P.D.; Gaikwad, S.M. (2014): Diversity and abundance of Odonata in parks and gardens of Pune city. *Journal of Entomology and Zoology Studies* 2(5): 308-316. (in English) [Poona(h), Maharashtra, India. "Man-made Parks and gardens play a vital role in maintaining urban insect diversity besides controlling pollution. The objective of this study was to find out the diversity and abundance of Odonates and to evaluate the importance of human-managed urban parks and gardens in supporting Odonata diversity. Thirty big and small parks and gardens of Pune city were surveyed during 2012-2013 at regular intervals to record the diversity of Odonates. A total of 1113 individuals were recorded comprising of 33 species under 6 families. The diversity and abundance of species depends on a number of factors like presence or absence of water bodies, size of the water bodies, level of human disturbances, shade cover, presence of emergent aquatic reeds, degree of pollution and garden management practice." 14584. Soniyagandhi, M.; Kumar, K. (2014): Impact of ag-

rochemicals on Odonata in rice (*Oryza sativa* L.) ecosystem. *JBiopest* 7(1): 52-56. (in English) ["Two supervised field experiments were conducted during kharif, 2012 and rabi, 2012-13 to study the impact of agrochemicals on the population of Odonata in rice at Pandit Jawaharlal Nehru College of Agriculture and Research Institute (PAJANCOA & RI), Karaikal, U.T. of Puduchery, India. The experiment was laid out in a randomized block design with eight treatments and three replications. It includes sole application of herbicide (Butachlor @ 2.5 litres/ha), fertilizers (NPK applied @ 50% N + 10% P + 10% K), insecticide (Chlorpyrifos @ 0.02 per cent seedling dip and foliar spray @ 1250 ml/ha), herbicide + fertilizer, herbicide + insecticide, fertilizer + insecticide, herbicide + fertilizer + insecticide and untreated check. In this experiment eight species of Odonata viz., *Agriocnemis pygmaea*, *Ceriatagrion coromandelianum*, *Ischnura aurora*, *Lestes elatus*, *Diplacodes trivialis*, *Orthetrum sabina*, *Pantala flavescens* and *Rhyothemis variegata* were identified during the crop growth period. The population of Odonata was recorded from 1st week to 12th week after transplanting. During kharif, the overall mean population of Odonata ranged from 0.19 to 0.65 /sweeping. It was found that the per cent reduction was higher in the treatment with herbicide + insecticide (70.7%) compared to the untreated check. During rabi, the overall mean population of Odonata ranged from 0.19 to 0.56/sweeping. A higher per cent reduction was observed in the treatment with herbicide + insecticide (6.07%) as in the kharif. It was concluded from both field experiments a higher population of Odonata was observed in the untreated check followed by the treatment with fertilizer alone while a low population was observed in the herbicide + insecticide treatment followed by insecticide alone." 14587. Swaegers, J.; Janssens, S.B.; Ferreira, S.; Watts, P.C.; Mergeay, J.; McPeck, M.A.; Stoks, R. (2014): Ecological and evolutionary drivers of range size in *Coenagrion* damselflies. *Journal of evolutionary biology* 27(11): 2386-2395. (in English) ["Geographic range size is a key ecological and evolutionary characteristic of a species, yet the causal basis of variation in range size among species remains largely unresolved. One major reason for this is that several ecological and evolutionary traits may jointly shape species' differences in range size. We here present an integrated study of the contribution of ecological (dispersal capacity, body size and latitudinal position) and macroevolutionary (species' age) traits in shaping variation in species' range size in *Coenagrion* damselflies. We reconstructed the phylogenetic tree of this genus to account for evolutionary history when assessing the contribution of the ecological traits and to evaluate the role of the macroevolutionary trait (species' age). The genus invaded the Nearctic twice independently from the Palearctic, yet this was not associated with the evolution of larger range sizes or dispersal capacity. Body size and species' age did not explain variation in range size. There is higher flight ability (as measured by wing aspect ratio) at higher latitudes. Species with a larger wing aspect ratio had a larger range size, also after correcting for phylogeny, suggesting a role for dispersal capacity in shaping the species' ranges. More northern species had a larger species' range, consistent with Rapoport's rule, possibly related to niche width. Our results underscore the importance of integrating macroecology and macroevolution when explaining range size variation among species." - 14588.** Takashima, K.; Nakamura, K. (2014): Geographical variation in egg diapause in *Sympetrum frequens*. *International Journal of Odonatology* 17(2-3): 81-87. (in English) ["The effects of photoperiod and temperature on the termination of egg diapause were examined in *Sympetrum frequens*. Eggs were obtained from adult females collected from three locations in Japan and incubated under short- or long-day photoperiods at a constant temperature of 25, 20, or 15°C. Egg diapause was eventually terminated in all treatments. Because differences in the average developmental time were small among the temperature treatments, it was concluded that the rate of diapause development is more rapid at lower temperatures, as in other Odonata species. A clear geographic trend was not found in the egg period, which may reflect the life cycle of *S. frequens*: the timing of reproduction is the same or even earlier in higher than in lower latitudes. Relatively large variations in embryonic period were found among populations and even within a population at 15°C, suggesting that the rate of diapause development is also variable. The results also suggested that a short photoperiod might prevent *S. frequens* eggs from hatching before the onset of winter." (2014): Interaction between juvenile narrow-claw crayfish, *Astacus leptodactylus* (Eschscholtz), and common water frog, *Rana esculenta* (L.), tadpoles or common blue damselfly, *Enallagma cyathigerum* (Charpentier), larvae during rearing under controlled conditions. *Arch. Pol. Fish.* 22: 257-264. (in English) ["Interactions were studied among juvenile *A. leptodactylus*, *R. esculenta* tadpoles and *E. cyathigerum*, larvae during rearing under controlled conditions. Interactions among the species studied had a positive impact on the survival of the crayfish, but the differences were not statistically significant ($P > 0.5$). The juvenile crayfish attacked and consumed the frog tadpoles and damselflies, but the juvenile crayfish very rarely fell prey to them. Only in the initial stage of life and during molting did larval damselflies prey upon juvenile crayfish. After 30 days of the experiment the interaction between crayfish-tadpoles and crayfish-larval damselflies was not noted to have had a statistically significant ($P < 0.05$) impact on crayfish growth. Juvenile crayfish aggression toward tadpoles and larval damselflies was often offset by the loss of even both chelipeds. In the crayfish-larval damselfly interaction the loss of both chelipeds was three-fold more common than it was in the crayfish-tadpole interaction; however, these differences were not statistically significant ($P > 0.5$). The effect of intraspecific interaction (crayfish-crayfish) was more a threat in terms of mortality from cannibalism than were interspecific interactions (crayfish-tadpole and crayfish-larval damselfly)." (2014): How do dragonflies recover from falling upside down?. *Bulletin of the American Physical Society, 67th Annual Meeting of the APS Division of Fluid Dynamics, Volume 59, Number 20, Sunday-Tuesday, November 23-25, 2014; San Francisco, California: 1 p.* (in English) [Verbatim: We release dragonflies from a magnetic tether so that they fall from an initially upside down orientation. To recover, the dragonflies roll their body 180 degrees every time. This set up offers an effective method for eliciting a stereotypical turn so that we can collect a large amount of data on the same turn. From the wing and body kinematics, we can tease out the strategy dragonflies use to roll their body. We record these flights with three zoomed in high-speed video cameras. By filming at 4000 to 8000fps, we measure the wing twist along each of the four wings as a part of the 3D wing kinematics. The shape of the wing twist depends on the interaction between the aerodynamic torque and the torque exerted by muscles, therefore providing clues on which of their four wings actively participate in creating the turn. By applying dynamic calculations to the measured kinematics, we further deduce the amount of torques dragonflies exert in order to turn.] Address: Wang, Z. 14600. Wang, X.; Zhang, Z.; Li, Q.; Wang, Q.; Yan, X. (2014): An information acquisition method based on dragonfly vision mechanism for observed target displacement measurement. *Sensor Letters* 12(2): 352-357. (in English) ["In recent years, river surface optical imaging velocimetry method has been developed as a feasible means for non-

contact river flow measurement during extreme flow conditions. However, due to the complex and variable physical and chemical properties of observed targets (i.e., flow tracers), and the various light disturbances, this kind of method is difficult to acquire the optical information of the observed targets precisely, which will induce failure in the following reconstruction of flow field as well as the river discharge measurement. To solve these problems, this paper presents a novel information acquisition method for observed target displacement measurement, which is inspired by dragonfly vision mechanism. It first designs a three-channel CMOS synchronous polarization imaging system to capture the polarization images of the river surface in three directions synchronously. Then, Stokes vectors are selected to compute the polarization degree image. Experimental results show that this method can improve the acquisition accuracy of the observed targets and provide a solid basis for the large-scale particle image velocimetry system." 14601. Ware, J.L.; Beatty, C.D.; Sánchez Herrera, M.; Valley, S.; Johnson, J.; Kerst, C.; May, M.L.; Theischinger, G. (2014): The petaltail dragonflies (Odonata: Petaluridae): Mesozoic habitat specialists that survive to the modern day. *Journal of Biogeography* 41(7): 1291-1300. (in English) ["Dragonflies are an ancient group of organisms, appearing in the fossil record for the last 325 million years; however, individual dragonfly species—like other arthropod species—are thought to persist only for ~10 million years. Here we report results suggesting that the species of one family—Petaluridae—are very much older. The eleven extant petalurids are found in Australia, New Zealand, Chile, Japan and North America. Through a Bayesian molecular phylogeny and BEAST relaxed molecular clock, we show that the petalurids originated ~160 million years ago, and that many of these species have persisted as independent lineages for ~70 million years. Analysis with LaGrange suggests that these species distributed along the coast of the supercontinent Pangaea, arriving at their current locations through continental drift. These long species 'lifespans' are surprising, especially for a group of habitat specialists with long development times (petalurid larvae live exclusively in fen habitats, and take several years to reach adulthood). As such these dragonflies challenge our understanding of the factors that drive extinction." (Authors)] Address: Ware, Jessica, Department of Biology, 415 Boyden Hall, Rutgers University, Newark, NJ, 07102, USA. E-mail: jware42@andromeda.rutgers

14602. Willet, J. (2014): Site condition monitoring for Odonata on seven SSSIs. Scottish Natural Heritage Commissioned Report No. 753: 57 pp. (in English) ["Background: This contract was to carry out Site Condition Monitoring (SCM) of Odonata assemblages at seven designated sites in Scotland. Abernethy SSSI had an additional survey as part of another contract for the northern damselfly, *Coenagrion hastulatum*, which is another notified feature; the results from both surveys have been included

in this report. This contract repeated the various SCM undertaken for Odonata on these sites in 2002, 2003 and 2005. Main findings: - Abernethy: four visits, 11 species recorded, proof of breeding for 10. - Coille Dalavil: two visits, 10 species recorded, proof of breeding for six. - Coille Mhor: two visits, eight species recorded, proof of breeding for four. - Coulin: two visits, 10 species recorded, proof of breeding for seven. - Glen Affric: three visits, 12 species recorded, proof of breeding for 10. - Loch Bran: two visits, nine species recorded, proof of breeding for seven. - Loch Maree: two visits, 11 species recorded, all breeding. - All sites are in favourable-maintained condition." 14603. Willigalla, C.; Jäckel, K.; Ackermann, J.; Koch, K. (2014): Veränderung der Libellenfauna (Odonata) der Stadt Mainz. *Mainzer naturwissenschaftliches Archiv* 51: 289-307. (in German, with English summary) ["From 2008 to 2013 the monitoring of dragon- and damselflies continued at 13 selected water sites within the urban area of Mainz. In total 44 species could be found, that is 66 % of the 67 species which currently exist in Rhineland-Palatinate. *Chalcolestes viridis*, *Coenagrion puella* and *Sympetrum striolatum* had a high consistency of 90 % within the study area, *S. sanguineum* even of 100 %. Compared to the study during the previous period from 2006 and 2007 the fauna of odonates in the urban area of Mainz enriched by four new species: *Coenagrion scitulum*, *Erythromma lindenii*, *Lestes virens* and *Brachytron pratense*. Moreover, some guests have been observed, namely *E. najas*, *Anax parthenope* and *Leucorrhinia pectoralis*. However, *Orthetrum brunneum* and *Ophiogomphus cecilia* were not sighted in the period of time from 2008 to 2013. The increase in the number of species in Mainz might probably be explained with the current climate-induced range shifts taking place in the dragonfly fauna. It is remarkable, however, that both higher species richness and higher consistencies could be found, despite the lower number of water bodies studied. In cases of good area knowledge it might thus be enough to monitor only selected reference waters to determine early population fluctuations." 14604. Yan, J.-Z.; Zheng, M.Z.; Li, Z.P.; Li, Q.S. (2014): Chapter 3: Mechatronics, Robotics and Control: Effects of Phase Relation between Forewing and Hindwing on Aerodynamic Performance in Dragonfly Flight. *Applied Mechanics and Materials* 709: 245-251. (in English) ["Dragonflies possess one of the most maneuverable flights among various insects. As the bionic Micro Air vehicles (MAVs) with the flight capabilities like dragonflies have been widely applied, detailed studies of dragonfly flight become critical and necessary for improvement and accomplishment of MAVs design. The phase relation between the forewings and hindwings is the most distinct feature of

dragonfly flight and it plays an important role in the aerodynamic performance. In this paper, both tethered and quasi-free flapping flight of the dragonfly *Pantala flavescens* was filmed using a high-speed camera in indoor laboratory. Dragonflies tend to flap in-phase when an additional force is expected, while out-of-phase flapping is conducive to the stability and control of flight. In the takeoff maneuver, the large- and small-amplitude wingbeat alternated. Dragonflies obtain a high acceleration rapidly by the suddenly enlarged wingbeat amplitude which increases by 42%, and maintain the velocity and make ready for following acceleration by the small-amplitude but high-frequency wingbeat with amplitude decreases by 51% and frequency increases by 30% relatively." 14605. Yoshioka, A.; Miyazaki, Y.; Sekizaki, Y.; Suda, S.; Kadoya, T.; Washitani, I. (2014): A "lost biodiversity" approach to revealing major anthropogenic threats to regional freshwater ecosystems. *Ecological Indicators* 36: 348-355. (in English) ["We proposed a method for evaluating the quantitative contributions of hypothesized focal pressures to biodiversity loss from freshwater ecosystems at regional or local scales. The method, called the "lost biodiversity approach" (abbreviated as "LBA") focuses on local biodiversity losses caused by focal pressures. Lost biodiversity is explicitly estimated by statistically modelling the relationships between factors or focal pressures and "differential biodiversity," defined as the difference between local biodiversity at a sampled site and regional species pool(s). We applied LBA to two cases in Japan: (1) the damselfly fauna of 56 agricultural ponds in a rural region sharing the same regional species pool and (2) freshwater fish fauna in the 13 largest river systems in Hokkaido, which includes multiple species pools. In the former, where nestedness of sampled damselfly assemblages was detected, and thus the difference between local species richness and species pool size was used as a simple indicator of differential biodiversity, biodiversity lost to invasive alien species was successfully quantified. In the latter case, where no nestedness of fish assemblages was detected, and differential biodiversity was analyzed based on an index weighting rare species, biodiversity lost to dams and eutrophication were quantified. The advantages of LBA supported by the case studies were its (1) feasibility, using species snapshot presence-absence data, (2) ability to quantify a baseline for each local community when focal pressures were removed, and (3) ability to evaluate impacts of focal pressures even if each local community belonged to a different species pool. This method will be effective in biodiversity hotspot areas." 14611. Andrew, R.J.; Verma, P.; Thaokar, N. (2015): A parasitic association of Odonata (Insecta) with *Arrenurus Dugés, 1834* (Arachnida: Hydrachnida: Arrenuridae) water mites. *Journal of Threatened Taxa* 7(1): 6821-6825. (in English) ["The parasitic association between water mites (*Arrenurus* spp.) and Odonata is virtually ubiquitous wherever habitats suitable for both taxa exist. Yet, very little is known about this association within and among the odonate species of India. Here, we present a report on this parasitic relationship in the population of odonates of Wena Dam of Central India observed during the years 2011 and 2012. Of the 376 odonates collected for observation, 35(9.3%) individuals belonging to seven species (*Acisoma panorpoides*, *Brachydiplax sobrina*, *Ceriatrion coromandelianum*, *Crocothemis servilia*, *Diplacodes trivialis*, *Neurothemis tullia tullia*, *Trithemis pallidinervis*) were found to be parasitized by the *Arrenurus* spp. mites. The mites were found attached to the undersurface of the thorax and abdomen. In all the cases, the thorax was found infested while only in seven individuals the abdomen as well as the thorax was found infested with mites. A maximum number of mites on an individual dragonfly was in *C. servilia* (293) followed by *T. pallidinervis* (134) while the highest parasitic load per individual host species was found in *T. pallidinervis* (70.25%) followed by *C. servilia* (32.6%). The average parasitic load per individual female and male was 39.77 and 8.9, respectively." 14612. Andrew, R.J.; Foerster, S. (2015): Egg shell ultrastructure of the dragonfly, *Micrathyrina dictynna* Ris (Anisoptera: Libellulidae). *Zoologischer Anzeiger - A Journal of Comparative Zoology* 254: 15-17. (in English) ["A highly specialized form of egg deposition occurs in *M. dictynna*, which attaches egg-masses onto the underside of leaves high above shallow streams in Central American rainfor-

ests. Here, we describe the ultrastructure of the egg chorion of *M. dictynna* to reveal structural adaptations related to this unusual form of oviposition. We find that the egg chorion is generally divided into a thin, sticky exochorion and a tough, hard, smooth endochorion. The exochorion of eggs collected from the peripheral region of egg masses, however, shows a separation into outer and inner exochorionic layers. The space formed between these layers develops numerous pillars. In eggs collected from the area between the periphery and central region of an egg mass, the exochorion exhibits irregular interconnected patches of elevated areas containing very fine superficial linear reticulations. We propose that the exochorion of peripheral eggs is functionally modified to form a plastron that regulates respiration and restricts water loss of eggs in the inner layers of the egg mass." 14613. Bello-Bedoy, R.; González-Santoyo, I.; Serrano-Meneses, M.A.; Vrech, D.; Rivas, M.; Munguía-Steyer, R.; Córdoba-Aguilar, A. (2015): Is allometry of sexual traits adaptive? A field test with territorial damselflies. *Biological Journal of the Linnean Society* 114(2): 327-334. (in English) ["Recent studies have linked static allometry of sexual traits to selective advantages, in terms of sexual selection. An underlying, yet untested, assumption is that the allometry of sexual traits confers higher mating success and/or survival. Here, we investigated whether the allometry of two sexual traits is related to male mating success and survival in two species of damselflies: wing size in *Paraphlebia zoe* and the red-pigmented wing spot in *Hetaerina americana*. We used large field-based data sets of marked-recaptured animals, in which we recorded male mating success and survival. Both sexual traits exhibited hyperallometric patterns; however, allometry was not linked to either mating success or survival. These results indicate that, at least during the period of sexual competition, allometry does not seem to be adaptive. Although our results may only apply to our damselfly study subjects (which nevertheless would require further tests in different seasons and/or study sites), our findings should encourage researchers to evaluate at least whether the assumed adaptiveness of sexual trait allometry holds for their study animals." 14614. Bennett, D.M.; Dudley, T.L.; Cooper, S.D.; Sweet, S.S. (2015): Ecology of the invasive New Zealand mud snail, *Potamopyrgus antipodarum* (Hydrobiidae), in a mediterranean-climate stream system. *Hydrobiologia* 746: 375-399. (in English) ["The New Zealand mud snail, *Potamopyrgus antipodarum*, is a widely distributed non-native species of management concern on four continents. In a southern California stream, *P. antipodarum* abundance, which ranged from ca. <10 to nearly 150,000 snails

m², was related to discharge and temperature patterns. Laboratory experiments indicated that *P. antipodarum* (1) survivorship decreased from 13 to 27°C, but its growth rate was higher at 13 and 20°C than 27°C; (2) grazing rates were similar to those of native algiivores in short-term trials; (3) grazing impact was greater than that of a native hydrobiid snail in longer-term trials; (4) ingested different diatom sizes than some other grazers; (5) reduced the abundances of medium-sized and large diatoms, and several filamentous cyanobacteria and chlorophytes, while increasing the relative abundances of tough filamentous chlorophytes (e.g., *Cladophora*); (6) impact on other grazing invertebrates was species specific, ranging from competition to facilitation; (7) reduced the survivorship of *Anaxyrus boreas* tadpoles; and (8) was consumed by non-native *Procambarus clarkii* and naiads of *Aeshna* and *Argia*. Ecological effects of introduced *P. antipodarum* are subtle, occurring primarily at transitory high densities, but flow regulation may enhance their effects by eliminating high flows that reduce their population sizes." 14615. Chang, Y.-H.; Wu, B.-Y.; Lai, C.-F. (2015): A study of the ecological benefits of the green energy landscape fountain. *Ecological Engineering* 75: 128-136. (in English) ["The overdevelopment of the environment in modern times has caused damage to our natural habitat and water resources. The survival of many species has been impacted. The main goal of this study is to explore the effects of green energy landscape fountain (GLF) on ecological preservation. The study site is located on the shore of an open water area within the campus of Mingdao University. The study site consists of three water tanks, buried inland, 1.5 m away from the shoreline. An ecological comparison study was performed on the quality of water between the three tanks of water. GLF is a floating island sized 60 cm × 60 cm made of PVC pipes with electricity supplied by solar panels. Changes in numbers of species were documented over a period of one year spanning 4 seasons in 3 different bodies of water. The results showed that the water with GLF installed had more species of organisms. 10 different species of organisms such as *Tetragnatha maxillosa*, *Polyrhachis dives*, *Araneus inustus*, *Ischnura senegalensis*, *Diaea subdola* were found in the water with GLF installed. 7 species often used as benchmark indicators of water pollution were found in water without GLF installed. The findings demonstrate the benefits of GLF on improving species diversity and the quality of water. This study also provides information which can be applied on landscape architecture, architecture and ecology design and engineering in the future." 14616. Chessman, B.C. (2015): Relationships between lotic macroinvertebrate traits and responses to extreme

drought. *Freshwater Biology* 60: 50-63. (in English) ["(1.) The prospect of increasing drought intensity in many river basins under climate change threatens the persistence of vulnerable freshwater species. Understanding how the traits of each species affect its resistance and resilience to drought may help to identify those species at most risk and elucidate the mechanisms by which impacts occur. (2.) I analysed macroinvertebrate monitoring data collected from rivers across Australia's Murray–Darling Basin (>106 km²) during the middle and later stages of the recent decade-long Millennium Drought and the initial post-drought period. I tested the ability of eight traits, expressing aspects of life history, diet and environmental tolerance, to explain changes in the broad-scale prevalence (the proportion of sites with observed presence) of macroinvertebrate families during and after the drought. (3.) The rate of basin-scale change in the riverine macroinvertebrate assemblage was least in the final stages of the drought. Immediately after the drought, the assemblage did not shift back towards its mid-drought state but instead moved further away. Eleven families that had a statistically significant fall in prevalence during the drought did not increase afterwards. (4.) Negative responses to drought were associated with slower maturation, absence of atmospheric respiration, high rheophily and low thermophily. Positive responses to cessation of drought were associated with having a holometabolous life cycle, greater requirements for dissolved oxygen, high rheophily and low thermophily. (5.) Because several traits were related to drought vulnerability, management to mitigate the adverse ecological effects of future droughts should consider a number of mechanisms by which drought has an effect. These include a loss of flowing water that supports rheophilous species, inadequate duration of wetting for species with a long aquatic phase, and effects of high temperature and hypoxia on species requiring cool conditions and well-aerated water. (6.) A revival of research on the life histories of freshwater invertebrate species and more information on oxygen requirements and temperature and desiccation tolerance are needed to improve our ability to predict the effects of drought." (Author) Taxa are treated at family level and include Odonata.] Address: Chessman, B.C., Centre for Ecosystem Science, School Biological, Earth & Environmental Sciences, Univ. of New South Wales, Kensington, NSW 2052, Australia. 14617. Dayaram, A.; Potter, K.A.; Pailles, R.; Marinov, M.; Rosenstein, D.D.; Varsani, A. (2015): Identification of diverse circular single-stranded DNA viruses in adult dragonflies and damselflies (Insecta: Odonata) of Arizona and Oklahoma, USA. *Infection, Genetics and Evolution* 30: 278-287. (in English) ["Highlights: •Discovered 24 distinct circular single-stranded DNA viral genomes from odonates. •First report of a ssDNA mycovirus in the New World. •High diversity among detected viruses. Abstract: Next generation sequencing and metagenomic approaches are commonly used for the identification of circular replication associated protein (Rep)-encoding single stranded (CRESS) DNA viruses circulating in various environments.

These approaches have enabled the discovery of some CRESS DNA viruses associated with insects. In this study we identified and recovered 31 viral genomes which represent 24 distinct CRESS DNA viruses from seven dragonfly species (*Rhionaeschna multicolor*, *Erythemis simplicicollis*, *Erythrodiplax fusca*, *Libellula quadrimaculata*, *Libellula saturata*, *Pachydiplax longipennis*, and *Pantala hymenaea*) and two damselfly species (*Ischnura posita*, *Ischnura ramburii*) sampled in various locations in the states of Arizona and Oklahoma of the United States of America (USA). We also identified *Sclerotinia sclerotiorum* hypovirulence-associated DNA virus-1 (SsHADV-1) in *P. hymenaea*, *E. simplicicollis* and *I. ramburii* sampled in Oklahoma, which is the first report of SsHADV-1 in the New World. The genome architectures of the CRESS DNA viruses recovered vary, but they all have at least two major open reading frames (ORFs) that have either a bidirectional or unidirectional arrangement. Four of the viral genomes recovered, in addition to the three isolates of SsHADV-1, show similarities to viruses of the proposed gemycircularvirus group. Analysis of the Rep encoded by the remaining 24 viral genomes reveals that these are highly diverse and allude to the fact that they represent novel CRESS DNA viruses." 14621. Dutra, S.; De Marco, P. (2015): Bionomic differences in odonates and their influence on the efficiency of indicator species of environmental quality. *Ecological Indicators* 49(1): 132-142. (in English) ["Highlights: •Those traits vary between the Neotropical Odonata (Zygoptera and Anisoptera). •Many small size, shade-seek species are associated to Zygoptera suborder. •Zygoptera species shows narrow ecological requirements. •They were associated to different shading, depth, and environmental integrity levels. The influence of environmental changes on organisms depends on their bionomic characteristics, such as mobility, body size, and resource use. Thermoregulatory and dispersal abilities may directly affect the use of odonates as bioindicators since organisms with low dispersal ability can track fine-scale environmental variations and are usually resource specialists. We investigated the utility of Anisoptera and Zygoptera as bioindicators testing possible relationships to their bionomic characteristics. We assessed the variation in species richness, composition, and indicator values in Cerrado areas by quantitative sampling of adult odonates in streams surrounded by different vegetation types, ordered by the degree of vegetation cover. Species composition was efficient in discriminating impacts affecting riparian vegetation, with low richness of rare and specialist species in impacted areas. Damselflies had more narrow requirements, associated to different shading, depth, and environmental integrity levels. No relation between body-size and species indicator value was observed. Despite this, the main use of those species as indicators, especially the Zygoptera, may be related to environmental disturbance created by changes on vegetation cover suggesting their potential use in the analysis of the environmental quality of riparian areas." 14624. Hammill, E.; Atwood, T.B.; Corvalan, P.; Srivastava, D.S. (2015): Behavioural responses to predation may explain shifts in community structure. *Freshwater Biology* 60: 125-135. (in English) ["(1.) Predators exert a strong selective force on the ecosystems in which they exist, thereby altering the structure of ecological communities and leading to the evolution of prey defences. However, how interspecific differences in defence ability affect habitat partitioning amongst competing prey species remains unresolved. (2.) We examined how prey defences affect species distribution in a natural ecosystem: the aquatic food web within Neotropical bromeliads. We first related differences in prey (mosquito) density to the presence and absence of predatory damselfly larvae. We then quantified behavioural responses to predators in the two most abundant mosquito species, and the effects of these behaviours on predator consumption rates. (3.) In the absence of damselflies, *Wyeomyia* was the most abundant mosquito genus in natural bromeliads. However, *Wyeomyia* numbers were reduced in the presence of damselflies. Numbers of the genus *Culex* increased with bromeliad size irrespective of the presence of damselflies. As a result of the differing effects of plant size and damselflies on the two genera of mosquito larvae, *Culex* were more numerous in large bromeliads containing damselflies. (4.) The most abundant *Culex* species, *Culex jenningsi*, had two kinds of behavioural defences: reduced movement and increased time at the water surface. These defences reduced damselfly attack rate on *C. jenningsi*, but not handling time. Consequently, consumption rate was reduced at all but the highest prey densities, altering the damselfly's functional response. Inducible defences were not

seen in the most abundant *Wyeomyia* species, *Wyeomyia abebela*, and pre-exposure to predation risk did not reduce predation on this species. (5.) Inducible behavioural defences, and the associated reductions in predation rate, evidently allow *C. jenningsi* to coexist with predators at a higher density than *W. abebela*. As predation risk is non-randomly distributed amongst bromeliads, divergence between mosquito species in their response to predation may contribute to the coexistence of a number of mosquito species across the landscape." (Authors)] Address: Hammill, E., School of the Environment, University of Technology Sydney, cnr Harris and Thomas St, Ultimo, NSW, 2007, Australia. E-mail: edd_hammill@hotmail.com

14625. Huang, Q.; Gao, J.; Cai, Y.; Yin, H.; Gao, Y.; Zhao, J.; Liu, L.; Huang, J. (2015): Development and application of benthic macroinvertebrate-based multimetric indices for the assessment of streams and rivers in the Taihu Basin, China. *Ecological Indicators* 48(1): 649-659. (in English) ["Highlights: •Multimetric indices (MMIs) based on benthic macroinvertebrates were developed and applied in the Taihu Basin. •We developed two MMIs for two specific aquatic ecoregions in the Basin. •The MMIs were robust and sensitive to anthropogenic ecological impairment. •The general ecological status of the Taihu Basin was lower than "good" status. The development of biological indicators for assessing ecological conditions in streams and rivers is urgently needed in China, particularly in heavily impacted regions. The aim of this study was to develop and apply benthic macroinvertebrate-based multimetric indices (MMIs) for the assessment of streams and rivers in the western hill and eastern plain aquatic ecoregions of the Taihu Basin. MMIs were based on samples collected from October 16 to November 8 2012 at 120 sites in streams and rivers. Least disturbed sites defined the reference conditions. Chemical water quality, physical habitat, and land use were used as criteria to identify reference sites in the basin. Metrics related to benthic macroinvertebrate richness, composition, diversity and evenness, pollution tolerance, and functional feeding groups were screened by range, sensitivity, responsiveness, and redundancy tests. Total number of taxa; percentage of Ephemeroptera, Trichoptera and Odonata (% ETO); Berger-Parker's index (BP); Biotic index (BI); and percentage of filterers-collectors (% FC) were used to construct the MMI for the western hill aquatic ecoregion (MMIW). Total number of taxa, percentage of Crustacea and Odonata (% CO), BP, BI, and % FC were used to construct the MMI for the eastern plain aquatic ecoregion (MMIE). The MMI scores were obtained by combining the rating categories (excellent, good, fair, poor, and very poor). The MMIs were tested using a separate subset of the data, and the results indicated that the newly developed MMIs were robust in terms of percentage of sites correctly classified, coefficient of variation, box-separation ratios, and separation powers. The ecological status was then evaluated based on the MMI scores. The results indicated that the general ecological status of streams and rivers in the Taihu Basin was rated lower than "good", the western hill aquatic ecoregion

was rated "fair" and the eastern plain aquatic ecoregion was rated "poor". Moreover, the MMIs showed a significant negative response to an increasing gradient of disturbance. Therefore, these preliminary MMIs can be used as assessment tools in ecological biomonitoring and management of the Taihu Basin." 14626. Kahilainen, A. (2015): Interactions and patterns between species diversity and genetic diversity. *Jyväskylä studies in biological and environmental science* 295: 68 pp. (in English) ["The similarities in the theories of community ecology and population genetics suggest that species diversity within and between communities and genetic diversity within and between populations are driven by the same four general mechanisms: (1) drift, (2) dispersal, (3) selection, and (4) the formation of new variants (i.e. speciation and mutation). Since, for both species diversity and genetic diversity, the relative significances of each of the first three mechanisms are very much influenced by characteristics of the environment, correlations between species diversity and genetic diversity, i.e. species-genetic diversity correlations (SGDCs), are expected. Considering that practical conservation most often focuses on species diversity (or surrogates thereof), SGDCs could provide information on how conservation and management decisions influence genetic diversities of populations, and thus also their viabilities. Furthermore, teasing apart the drivers of the SGDCs can offer mechanistic explanations for diversity and therefore suggest a process-based approach to conservation. I studied the generalizability of SGDC and the role of environmental characteristics by means of a literary review and empirical studies on natural dragonfly and damselfly communities. I then conducted individual-based simulations to assess how inbreeding depression due to loss of genetic diversity can influence extinction rates in neutral multispecies metacommunities. My results suggest that SGDCs are highly variable in natural systems and that interactions between ecologically similar species can influence their genetic structures. Therefore, the results question the utility of using species diversity or genetic structures of ecologically similar species as surrogates for genetic diversity of species of conservation concern. Furthermore, my results suggest that if intraspecific genetic diversity is not explicitly considered, the extinction rates in multispecies metacommunities might be underestimated." 14627. McBurnie, G.; Davis, J.; Thompson, R.M.; Nano, C.; Brim-Box, J. (2015): The impacts of an invasive herbivore (*Camelus dromedaries*) on arid zone freshwater pools: An experimental investigation of the effects of dung

on macroinvertebrate colonisation. *Journal of Arid Environments* 113: 69-76. (in English) ["Highlights: •Macroinvertebrate abundance was higher in the control mesocosms. •Pollution tolerant taxa such as mosquito larvae were common in treatment mesocosms. •Sensitive fauna, such as larval dragonflies were more common in the controls. Aquatic ecosystems in arid environments provide important refugia and 'stepping-stones' of connectivity for aquatic fauna. Aquatic ecosystems in central Australia are vulnerable to degradation due to the impacts of invasive herbivores such as camels, which degrade small desert waterbodies through drinking, trampling, and fouling with dung. In this study we assessed the impacts of camel dung on the water quality and macroinvertebrate colonization and community composition of small arid zone freshwater pools using experimental mesocosms. Camel dung (2 kg) was added to half the mesocosms (the treatment), the remaining mesocosms (without camel dung) acted as the controls. All mesocosms were sampled weekly for water quality, nutrients, chlorophyll a and macroinvertebrate richness and abundance, over an eight week period during summer. Macroinvertebrate abundance was higher in the control mesocosms in comparison to the treatment mesocosms. Pollution tolerant taxa such as mosquito larvae were common in treatment mesocosms, while sensitive fauna, such as larval mayflies and dragonflies were more common in the controls. The latter are predators and appeared to have a major influence on community composition. Our results reinforce the need for active management of invasive herbivores to protect aquatic biodiversity and to manage potential disease-vector species in central Australia waterbodies." (Authors)] Address: McBurnie, Glenis, Northern Territory Department of Land Resource Management, P.O. Box 1120, Alice Springs NT 0870, Australia. E-mail: glenismcb@gmail.com

14628. Monteiro Júnior, C.; Juen, L.; Hamada, N. (2015): Analysis of urban impacts on aquatic habitats in the central Amazon basin: Adult odonates as bioindicators of environmental quality. *Ecological Indicators* 48: 303-311. (in English) ["Thirty streams were surveyed in urban and natural settings in the municipality of Manaus in the central Amazon basin (Brazil) with the objective of identifying the species of adult odonates that can be used as bioindicators of environmental quality. The data collected were used to test the hypothesis that species in the suborder Zygoptera are indicators of better-preserved environments due to their smaller body sizes and reduced tolerances to habitat modification, whereas species in the suborder Anisoptera were presumed to be indicators of impacted habitats with no vegetation. The habitats were classified as preserved, intermediate, and degraded, based on their environmental characteristics. A total of 908 specimens were collected, representing 60 species. The results of the indicator value (IndVal) identified 13 species as indicators of environmental quality, of which nine were typical of preserved habitats, two of intermediate habitats, and four of modified habitats (intermediate or degraded).

Odonate species richness declined with increasing urbanization, a pattern also presented by the zygopterans, although anisopteran species richness was higher in intermediate habitats. Zygopteran species showed high fidelity/specificity for preserved habitats, although a small number of the species of this suborder showed a similar relationship with intermediate or degraded habitats, whereas anisopterans were associated only with disturbed habitats (intermediate and degraded). Overall, the results indicate that the diagnosis of the adult odonate community can provide a rapid and effective tool for evaluation of environmental quality. As many species are stenotopic, they can be used as indicators of good habitat quality, whereas some of the more eurytopic species can indicate disturbed habitats." 14630. Nie, Z.; Tian, S.; Tian, Y.; Tang, Z.; Tao, Y.; Die, Q.; Fang, Y.; He, J.; Wang, Q.; Huang, Q. (2015): The distribution and biomagnification of higher brominated BDEs in terrestrial organisms affected by a typical e-waste burning site in South China. *Chemosphere* 118: 301-308. (in English) ["Highlights: •The terrestrial ecosystem at the e-waste site has been contaminated by PBDEs. •Deca-BDE is found in the highest concentration among 21 kinds PBDEs in all samples. •Higher brominated congeners were the dominant congeners, especially BDE-209. •Eleven PBDE congeners were biomagnified in the examined food chain. •The feeding habit of terrestrial species may be affect PBDE accumulation. Soil, vegetation, and several terrestrial species including turtledove, chicken, goose, grasshopper, dragonfly, butterfly and ant, were collected from an area surrounding a typical e-waste burning site in South China. The samples were examined to investigate the lev-

els, congener profiles, and biomagnification extent of polybrominated diphenyl ethers (PBDEs) that may be present in the environment as a result of the e-waste, which was processed in a crude recycling style. Elevated levels of S21PBDEs were found in the biota (101–4725 ng g⁻¹ lipid weight (lw)), vegetation leaf (82.9–319 ng g⁻¹ dry weight (dw)) and soil samples (5.2–22 110 ng g⁻¹ dw), indicating that PBDE contamination in the samples collected from the e-waste burning site may pose risks to the local terrestrial ecosystem and local populations. Higher BDE congeners, especially deca-BDE (BDE-209) were the dominant homologs in organisms and nonbiological matrices, followed by nona-BDE and octa-BDE. Biomagnification factors (BMFs) were calculated as the ratio of the lipid-normalized concentration in the predator to that in the prey. The highest BMF (3.4) was determined for BDE-153 in the grasshopper/turtledove food chain. Other higher brominated congeners, such as BDE-202, -203, -154, -183 and -209, were also biomagnified in the terrestrial food chain with BMFs of 1.7–3.3. BDE-47, -100, and -99 were not biomagnified in the examined food chains (BMFs < 1), which suggests that bioaccumulation and biotransformation of PBDEs in terrestrial ecosystems could be distinguished from those in aquatic ecosystems." 14631. Razeng, E.; Watson, D.M. (2015): Nutritional composition of the preferred prey of insectivorous birds: popularity reflects quality. *Journal of Avian Biology* 46: 89-96. (in English) ["Food availability is emerging as a key determinant of avian occurrence and habitat use in a variety of systems, but insectivores have received less attention than other groups and the potential influence of nutritional quality has rarely been considered. Rather than a uniform food source, arthropods vary greatly in terms of nutritional composition, but does this variation translate into differential consumption? Building on previous work that demonstrated clear preference for some arthropod groups by 13 species of ground-foraging insectivores, we compare the nutritional composition of these arthropod groups with other groups commonly encountered but seldom consumed in the same habitat types. Using samples of arthropods collected from a eucalypt woodland in southern Australia, we found the high frequency prey groups (Coleoptera, Lepidoptera, Orthoptera and Araneae) consistently contained higher fractions of crude protein and total fat than the low frequency groups (Diptera, Hymenoptera and Odonata). Even more clear-cut differences were noted in terms of micronutrients; high frequency prey containing significantly greater concentrations of seven elements than low frequency prey and significantly greater amounts per individual arthropod for all eleven elements measured. These results indicate that the nutritional quality plays an important role in prey selection in insectivores and suggests that micronutrients may be more important determi-

nants of prey choice than previously recognized. Integrating these findings with previous work suggesting food limitation may constrain distribution patterns of birds in fragmented landscapes, we contend that variation in nutritional quality helps explain observed patterns in insectivore diets and occurrence. In addition to explaining why smaller and more disturbed habitats are unable to support resident insectivore populations, this bottom-up mechanism may underlie the disproportionate sensitivity of insectivores to land-use intensification." 14634. Vanacker, M.; Wezel, A.; Payet, V.; Robin, J. (2015): Determining tipping points in aquatic ecosystems: The case of biodiversity and chlorophyll a relations in fish pond systems. *Ecological Indicators* 52: 184-193. (in English) ["Highlights: •We compare different statistical methods and diversity indices to determine tipping points. •We compare tipping points in different taxonomic groups. •SEGMENTED and Jackknife first order are the most adequate method and diversity index to determine tipping points. •Aquatic vascular plants are the best taxonomic group to respond to eutrophic changes. Abstract: The management of biodiversity in aquatic ecosystems requires knowing the

state of water quality linked to regime shifts in various taxonomic groups. We examine this question by studying the fish ponds in the Dombes region, France. These waterbodies are characterized by a high diversity of species. High levels of nutrients due to certain fish farming practices may cause significant eutrophication leading to loss in biodiversity and a shift from high coverage of aquatic vegetation to phytoplankton dominance may also be observed. The aim of this study is to assess tipping points, thresholds for effect, along a gradient of chlorophyll a in different taxonomic groups: aquatic vascular plants, phytoplankton, dragonflies and aquatic macro-invertebrates. Tipping points are analyzed with three different statistical methods: a method which evaluates tipping points with a difference in the mean (TMEAN), a second method which evaluates tipping point by comparing the mean and linear regressions before and after the tipping point (FSTAT) and third a method which evaluates linear regressions with a pivotal tipping point (SEGMENTED). We also compare tipping points for the different taxonomic groups using five different diversity indices: Observed richness, Jackknife first order, Fisher's alpha, Simpson index and Evenness. Our results show that there is an important variation in tipping points following the three statistical methods, but the SEGMENTED is the best method for evaluating tipping points. We observe a high difference of tipping point values for the different taxonomic groups depending on the diversity indices used. Jackknife first order has a better performance to evaluate a eutrophic change according to the diversity than the other indices. In all taxonomic groups, aquatic vascular plants are the most impacted by the chlorophyll a and almost all their tipping points are observed around 60 µg/L chlorophyll a concentrations. No significant relationship is found between chlorophyll a and phytoplankton diversity, while the two other groups, dragonflies and macro-invertebrates, are both impacted by the chlorophyll a but their relevant tipping points are situated in higher values than aquatic vascular plants." 14635. Verma, P.; Andrew, R.J.; Khrabvu, K. (2015): Histology of the post ovarian genital complex of the dragonfly *Pantala flavescens* (Fabricius, 1798) (Odonata: Libellulidae). *International Journal of Research Studies in Biosciences* 3(1): 82-89. (in English) ["In *P. flavescens*, the post ovarian genital complex (POGC) consists of a pair of long thin spermatheca with bulbous tips, a small, spherical dorsal bursa copulatrix and a large ventrally placed vagina. The wall of the POGC is basically composed of an outer muscle layer, middle epithelial layer resting on a basement membrane and an internal layer of cuticle. It is externally covered in muscle bands. The internal lining of ST is annulated with cuticular rings and is formed of 3-4 layers of cuticle consecutively undergoing sclerotization. The bursa copulatrix is small and spherical with a thick layer of folded cuticular intima. The fertilization pore is in the form of a valve covered with cuticular spines. The bursa communis

is a tunnel like structure formed by three plates, a median-dorsal plate and paired lateral plates. The vagina is divided into anterior and posterior regions- the anterior region bears large number of small flat finger-like processes or stubs while the posterior region is a long, large, laterally folded, sac like structure which tapers into the female gonopore." 14636. Weterings, R.; Umponstira, C.; Buckley, H.L. (2015): Predation rates of mixed instar Odonata naiads feeding on *Aedes aegypti* and *Armigeres moulti* (Diptera: Culicidae) larvae. *Journal of Asia-Pacific Entomology* 18(1): 1-8. (in English) ["Highlights: •Predation rates were negatively related to predator densities. •Predation rates were positively related to prey densities. •Predation rates were much lower and realistic compared to previously recorded rates. •Predation rates based on large Odonata naiads overestimate actual predation. In Thailand several important diseases are transmitted by mosquitoes. Many vector control programs focus on the reduction of these medically important mosquitoes through the application of pesticides, bed-nets and the introduction of biological control agents. Odonates naiads are important, naturally occurring predators of vector mosquitoes. To estimate the predation rates of odonate species in Thailand, we conducted an experiment in which the predation rates were compared across a range of predator and prey densities. We used seven different predator species from different instars that represented the composition of naiads in our study area. Body sizes ranged between 2.6 mm and 15.9 mm. Two different prey species were used, larvae of the mosquito *Armigeres moulti* Edwards, 1914 and *Aedes aegypti* L. 1762. Predation rates showed a positive non-linear relationship with prey densities and a negative non-linear relationship with predator densities. The mean (\pm SE) predation rates per predator were 6.2 (\pm 0.8) individuals per 24 h for dragonfly naiads and 5.1 (\pm 0.7) for damselfly naiads. Predation rates were very low compared to previously recorded rates. However, unlike previous research we did not focus on single species in a late stage of development, but on multiple species in all stages that resembled the natural Odonata community composition." 14637. Xu, M.; Fincke, O.M. (2015): Ultraviolet wing signal affects territorial contest outcome in a sexually dimorphic damselfly. *Animal Behaviour* 101: 67-74. (in English) ["Highlights: •We investigated the role of sex-specific UV-reflective wing ornamentation in *Megaloprepus caerulatus*. •Contest duration and dynamics of males were consistent with opponent-only assessment of wing band size. •UV reflectance of male wing band serves as a 'biological billboard' for body size. •UV reflectance of female white tips did not affect sex recognition. •First direct evidence that UV reflectance of wing ornament affects contest outcome in invertebrates. Ultraviolet (UV) reflectance and UV

vision are both common among animals and are known to function in mate choice and male–male competition among numerous vertebrates. In comparison, examples of functional UV reflectance among invertebrates are scarce. In a territorial damselfly (*Megaloprepus caerulatus*), data from natural territorial contests indicated that males assessed the male wing band of rivals. We investigated the functions of (1) UV reflectance of the male-specific white wing band in territorial contests by staging contests between size- and age-matched, control and UV-reduced males, and (2) UV reflectance of the female-specific wing tip in sex recognition by presenting control and UV-reduced females to territorial males. Results showed that males whose UV reflectance of the white wing bands was reduced were more likely to lose contests. This effect dissipated late in the reproductive season, when breeding sites typically decrease in value. UV reflectance of the female wing tips did not affect male sex recognition, nor did it affect the detectability of a female at a male territory. Our study provides the first direct evidence from invertebrates, and one of the few among all animals, that UV reflectance of wing ornamentation affects the outcome of male contests in the field." (in Dutch, with English Summary) ["In the agricultural area around Lilbosch Abbey (The Netherlands) many ponds were created with a view to increasing the natural value of the area- Creation and management of the ponds were based on knowledge of the ecology of the local fauna, with particular regard for dragonflies. The ponds have been constructed with very gentle slopes (1:5) and they are not too deep (max. 1 meter below ground level). In dry summers the water level is about one meter below ground level. Unlike the usual situation, the ponds are not fenced in with barbed wire, so cattle are able to approach them. The grazing impact is very low (one cow or horse on two or three ha) and there are at least six ponds within the area where the cattle arc grazing, which seems to have a very positive effect on the dragonfly fauna. The article discusses the effects of this management and compares the dragonfly fauna of ponds with relative steep slopes and those with gentle slopes. In the few years since the ponds were created and the extensive grazing management implemented, the number of dragonfly species has increased spectacularly. Twenty-nine species were recorded, which means that this has become one of the better dragonfly areas in the Netherlands. At least twenty species have colonized this area. The article also discusses the various dragonfly species recorded and their future in this area." (Authors)] Address: Hermans, J.T.; Hertestraat 21, NL-6067 ER Linne, The Netherlands. 14639. Danielsson, I. (1998): Mechanism of sperm competition in insects. *Ann. Zool. Fennici* 35: 241-257. (in English) ["Sperm competition has been demonstrated in a variety of insects and is in addition to ecological resource distribution and sex ratios, generally believed to

play a major role in the evolution of insect reproductive strategies and mating systems. In this paper. I review the main theories and some of the empirical evidence regarding sperm competition in insects. Sperm utilization is shaped by selection on both males and females, sometimes in opposite directions. Here I focus mainly on adaptive mechanisms for sperm priority and paternity assurance, and consequences of such adaptations for females. I also evaluate the importance of the conflicts between the sexes for the evolution of mating behaviour from existing theory and available empirical evidence. Some urgent research areas for future workers are suggested. An explanation for the large intraspecific variation in last male sperm priority is still lacking. To this end. we need detailed studies of the mechanisms of sperm usage within the female, and to what extent females influence postcopulatory fertilization processes." 14641. Little, B. (2000): *Companion Planting*. New Holland Publishers Ltd: 96 pp. (in English) ["In an age of increasing hostility towards chemical control of the food we eat, "Companion Planting" is the ideal guide to working with nature, to produce healthy and bountiful crops. There is something fascinating about companion planting - it is immensely enjoyable to be able to outwit one's enemies with simple, tried-and-tested methods. More and more gardeners are recognising the good sense of

working with nature instead of trying to club it into submission. Entertaining and often anecdotal, the snippets of wisdom in this book are arranged alphabetically, allowing the reader to easily search for a particular plant or garden pest. In many cases the author offers a method for encouraging a healthy crop or discouraging a nuisance to the gardener. Her summary of good and bad garden companions is a useful quick reference tool for gardeners planting beds or containers of vegetables and herbs." (Publisher) The book includes two notes on damselflies and dragonflies as companions in gardening and pest control.] Address: not stated

14642. Ramírez, A. (2000): 4.1.2 Dragonflies and damselflies of Costarican cloud forests. In: N. M. Nadkarni and N. T. Wheelwright (Eds.): *Monteverde: ecology and conservation of a tropical cloud forest*, Oxford Univ. Press, Athens GA.: 97-[Verbatim: Dragonflies and damselflies (order Odonata) are the best known of aquatic insects due to their large size, brilliant colours, and conspicuous flight. Dragonflies perch with their wings outstretched; damselflies rest with their wings held together above the body. Adults and nymphs are voracious predators of smaller insects. Nymphs are aquatic and live in Standing or running water. Fourteen families and 280 species of Odonata are recorded from Costa Rica (Paulson 1982), although the actual number is higher. Odonate diversity is greatest in the lowlands and decreases with altitude. Seventy species have been collected from areas above 1200 m, which represents 25% of the species in the country. Of these, only 13 species are restricted to altitudes above 1200 m. However, cloud forests have not been well collected. Biogeography of the cloud forest fauna indicates 41% of the species are of South American origin, 28% are Central American (including endemics), and 7% are North American. The rest are widespread species whose origins are unclear. Some odonate genera contain discrete lowland and highland species. One highland species, *Sympetrum nigrocreatum*, is probably derived from the widespread mid-elevation species *S. illotum*. *Philogenia peacocki* has only been found in cloud forests, whereas *P. carrilliea* is more commonly found at lower altitudes. In the same stream, *P. peacocki* has been found inhabiting the upper parts but is replaced by *P. carrilliea* at lower altitudes, with some overlap of the two species around 1200 m. Some cloud forest species occur at intermediate altitudes (800-1500 m). For example, *Heteragrion majus*, a characteristic inhabitant of streams in cloud forests, is also present at lower altitudes (down to 800 m) in streams that share characteristics with cloud forest streams such as high humidity, steep slopes, and low temperature (17—20°C). Of the species recorded from cloud forests, 60% have nymphs that live in open areas of lakes, marshes, and ponds; 38% inhabit shaded streams; and 2% live in specialized habitats such as bromeliads and tree holes. These proportions depend on the availability of the habitats. In general, open habitats have been better studied than forest streams (Paulson 1982). Nymphs are adapted to live in specific habitats, for exam-

ple, accumulations of dead leaves in riffles. The most limiting factor is the availability of habitat suitable for nymph development. Most species tolerate only narrow ranges of conditions such as temperature, oxygen level, forest cover, types of aquatic vegetation and water pollution. They are good biological indicators and their Conservation depends on habitat preservation. Few species are well adapted to highly disturbed habitats.] Address: Ramirez, A., Univ. Georgia, Inst. 14643. Hollows, J.W.; Townsend, C.R.; Collier, K.J. (2002): Diet of the crayfish *Paraneohpops zealandicus* in bush and pasture streams: insights from stable isotopes and stomach analysis. *New Zealand Journal of Marine and Freshwater Research* 36: 129-142. (in English) ["*P. zealandicus* stomachs from streams in both native bush (mainly tree leaves and dicotyledonous seeds) and exotic pasture settings (mainly grass stems and monocotyledonous seeds) were dominated by allochthonous material. More detritus occurred in stomachs in autumn-winter than in spring-summer, but quantities were similar in crayfish from native bush and pasture streams. The stomachs of larger crayfish contained a significantly greater proportion of detritus than smaller individuals. Aquatic invertebrates were the second most abundant dietary category by volume, with highest values in winter, but there were no significant differences between land uses or crayfish size classes. A wide range of invertebrates was eaten by crayfish, with mayfly nymphs, chironomid larvae, and snails predominating. The latter were numerically more prominent in crayfish from bush than pasture streams. Terrestrial invertebrates were recorded from 4% of stomachs, but there were no significant differences in relation to land use, season, or crayfish size class. Despite aquatic invertebrates making up <4% of stomach volumes on average, stable isotope analysis indicated a greater importance for invertebrate prey in terms of assimilation and incorporation into crayfish biomass. Allochthonous detritus and moss appeared to be unimportant. Whereas the results of stomach analysis provided some evidence of an ontogenetic shift, with detritus assuming greater importance in larger crayfish, this pattern was not supported by isotope analysis because invertebrate prey appeared more important to the diet than detritus. An unidentified carbon source, depleted in ^{13}C and perhaps of microfloral origin, seems to be an important energy source for crayfish in both stream types." (Authors) The diet included one unidentified dragonfly (larva?).] Address: Hollows, J.W., Fish & Game Otago, P.O. Box 76, Dunedin, New Zealand. E-mail: j.hollows@fishgame

(2005): Ponds and pools as model systems in conservation biology, ecology and evolutionary biology. *Aquatic Conserv: Mar. Freshw. Ecosyst.* 15: 715-725. (in English) ["(1.) Ponds and pools, broadly defined in this paper to include all small and shallow standing waters that permanently or temporarily contain water, are numerous, diverse and important from a conservation point of view. We here argue that ponds and pools offer powerful potential for studies in ecology, evolutionary biology and conservation biology. (2.) An outline is given of the characteristics of ponds and pools that make them good model systems for large-scale surveys and hypothesis testing through experimental manipulation. Such studies will not only increase understanding of community and genetic structure, as well as of patterns of biodiversity, in small aquatic habitats themselves, but may also contribute significantly to testing general theory. (3.) These merits are illustrated by the recent progress on the understanding of the relative importance of local versus regional factors in structuring populations and communities, as well as of the impact of hydroperiod on community and ecosystem functioning." (Authors) The paper includes references to Odonata.] Address: De Meester, L., Laboratory of Aquatic Ecology, Katholieke Universiteit Leuven, Charles de Bériotstraat 32, 3000 Leuven, Belgium. 14650. Giannini, N.P.; Kalko, E.V. (2005): The guild structure of animalivorous leaf-nosed bats of Barro Colorado Island, Panama, revisited. *Acta Chiropterologica*

7(1): 131-146. (in English) ["We examined data sets on dietary composition of a rich (15 species) assemblage of animal-eating Neotropical leaf-nosed bats (Phyllostomidae: Phyllostominae) that occur syntopically on Barro Colorado Island, Panama. Our aim was to test previously postulated trophic structure of phyllostomines in the light of alternative analytical techniques and new data. The trophic structure of this assemblage, according to new results from Correspondence Analysis, has two main trends of variation: a gradient of increased carnivory (axis 1) and a gradient involving plant and arthropod consumption (axis 2). This rejects previous hypotheses of this guild in which the structure was described as a complex of many independent discrete resources. Although all data sets agree that coleopterans as a group are an important food item for most species, Phyllostominae bats are not typically durophagous; i.e., they lack cranial and dental adaptations for rapid processing of hard-shelled arthropods as found in other bat families. Furthermore, insectivory varies inversely with body size, and is gradually replaced by carnivory in association with increasing mass and limited dental modifications. Together with CA results, this suggests that carnivory is an extreme of animalivory rather than a qualitatively distinct feeding habit among Phyllostominae bats. This conclusion fits biomechanical data that indicate that carnivorous bats are bigger and only modestly modified versions of soft-insect specialists." (Authors) The diet of *Micronycteris hirsuta* and *M. microtis* included a few Odonata.] Address: Giannini, N.P., Dept of Mammalogy, American Museum of Natural History, Central Park West at 79th Street, New York, NY 10024-5192, USA. 14665. Dolný, A.; Matějka, P. (2007): A contribution to population biology of *Libellula fulva* (Odonata: Libellulidae) on coal sludge sedimentation pond (Karviná – Czech Republic). *Ekológia (Bratislava)* 26(4): 341-351. (in English) ["The basic ecological characteristics of the only known population of *Libellula fulva* Müller in the Czech Republic (estimate of population size, territoriality, time of occurrence, mating season etc.) including the description of the habitat and overall dragonfly assemblage in the researched locality are reported. In 2002, we marked 76 males, total number of recaptures was 31. In 2003, we marked 114 males, there was a total 50 recaptures. The estimate of the Schnabel population density of adult males

in the 2002 was 123 specimens (the 95% confidence limits: 88–178). The estimate of the male population size in 2003 was 188 specimens (the 95% confidence interval: 145–271). In 2002 imago activity lasted 70 days, in 2003 only 41 days. In 2002, imago activity became apparent at the end of April; the first immature imago was discovered on 27-IV-2002. The maximum discovered life span of adult specimens we identified to be 16 days in 2002. In 2003 it was 26 days. Immature adults were recorded no later than in the first two weeks of imago occurrence. Interspecific territoriality was observed mainly in relation to *Orthetrum coerulescens*. We recorded 33 species of the dragonflies in the researched locality (12 species of Zygoptera, 21 species of Anisoptera). The only known area with the autochthonous occurrence of *Libellula fulva* in the Czech Republic is the Karviná-Doly – Mokroš locality, where *L. fulva*, curiously, evolves in a rather extreme environment i.e. a dam, which until recently was used for the sedimentation of coal sludge. Furthermore, this species was considered missing or rather extinct from 1913 to 1999 in the whole of the Czech Republic." M.Sc. thesis, Department of Life Science, Tunghai University: 42 pp. (in English, with Chinese summary) ["We used an endemic Formosan damselfly, *Euphaea formosa* (Insecta: Odonata: Euphaeidae) in Taiwan to investigate the pattern of contemporary population genetic structure using both mitochondrial cytochrome oxidase II (COII) and nuclear internal transcribed spacer (ITS) genes, and to discuss geohistorical events and life history characteristics that may have contributed to the observed patterns. Our results suggested that there was substantial gene flow among populations. Two distinct haplotype clades, one western restricted and one widespread clade, were identified based on COII phylogeny. The COII western clade, which showed a significant isolation by distance pattern, may colonize Taiwan due greatly to recent glacial events. Historical demography estimated using Bayesian skyline plot (BSP) and mismatch distribution showed a pattern of recent population expansion. Significant negative Tajima's D and Fu's FS values coupled with star-like networks of COII widespread clade and ITS also indicate population expansion. We conclude that the colonization and demographic expansion of damselfly populations were likely the result of increased available habitats during late Pleistocene." (Author)] Address: not stated

14697. Jones, R.W. (2009): The impact on biodiversity, and integrated control, of water hyacinth, *Eichhornia crassipes* (Martius) Solms-Laubach (Pontederiaceae) on the Lake Nsezi – Nseleni River System. M.Sc. Thesis, Department of Zoology and Entomology Rhodes University: 115 pp. (in English) ["Water hyacinth, a free floating

aquatic plant was discovered by C. von Martius in 1823 in Brazil. It is believed to have been introduced into South Africa, as an ornamental plant, in 1908 to the Cape Province and Natal. Since its introduction, water hyacinth has spread throughout South Africa to the detriment of all aquatic systems that it has been introduced to directly or indirectly. The weed was first positively identified on the Nseleni and Mposa rivers on the Nseleni Nature Reserve which is a protected area near Richards Bay in KwaZulu-Natal in 1982 and formed a 100% cover of the river by 1983. An integrated management plan was implemented in 1995 and resulted in a reduction of the weed from a 100% cover to less than 20% cover in 5 years. The keys to success of the water hyacinth integrated management plan, presented here, were finding the source of the weed, mapping the extent of the water hyacinth infestation, identifying sources of nutrient pollution, appointing a champion to drive the programme, dividing the river into management units, consultation with interested and affected parties, judicious use of herbicides and biological control and a commitment to follow-up. This study further showed that water hyacinth on the Nseleni and Mposa river systems had a negative impact on the biodiversity of the protected area and the control of water hyacinth resulted in the recovery of the benthic invertebrate, amphibian, reptile, fish and avian fauna. The implementation of this integrated management plan was very cost-effective and serves as a model approach to the control of water hyacinth in both South Africa and the rest of the world." (Author) Odonata are treated at the family level.] Address: Jones, R.W., Dept of Zoology & Entomology Rhodes University, P.O.Box 94, Grahamstown 6140. USA

14701. Roble, S.M.; Carle, F.L.; Flint, O.S. (2009): Dragonflies and damselflies (Odonata) of the Laurel Fork recreation area, George Washington National Forest, Highland County, Virginia: Possible evidence for climate change. In: S. M. Roble and J. C. Mitchell (eds.). 2009. *A Lifetime of Contributions to Myriapodology and the Natural History of Virginia: A Festschrift in Honor of Richard L. Hoffman's 80th Birthday*. Virginia Museum of Natural History Special Publication No. 16, Martinsville, VA: 365-399. (in English) ["The Odonata fauna of the Laurel Fork Recreation Area in the George Washington National Forest, Highland County, Virginia, was sampled on more than 50 dates between 1971 and 2008. A diverse fauna of 66 species (43 dragonflies, 23 damselflies) was documented in the study area, including four species not recorded elsewhere in Virginia and four others that have been recorded from only one other site in the state (two from nearby sites in the same county). Most of the species are confirmed or suspected to breed in the study area at beaver ponds, seepage habitats, headwater streams, or the mainstem of Laurel Fork. Twenty-one species were documented by the collection or observation of only 1-2 adults during the entire study, suggesting that they may have been migrants, strays, immigrants, or rare and declining species. Approximately a quarter of the species recorded in the study area are at or near their southern range limits, and a third of the Laurel Fork fauna is included on the Virginia Division of Natural Heritage program's current list of state-rare species. Collecting occurred primarily during two periods, the first from 1971-1982 and the second from 1992-2003. Five boreal species were only collected during the first period and 12 austral species were only collected during the second period, suggesting a change in community structure that is concordant with climate warming. Record early or late flight dates for Virginia populations were documented for 24 species. The Laurel Fork Recreation Area is a regionally significant site for the protection of biodiversity." 14705. Hermans, J.H. (2010): The dragonfly fauna of southern Limburg. *Natuurhistorisch Maandblad* 99(9): 189-200. (in Dutch, with English summary) ["The article presents an overview of our present knowledge about the dragonflies of the southern part of the province of Limburg. 55 species of dragonflies were observed between 1990 and 2007. Dragonflies of oligotrophic waters (moorland pools or bogs) such as *Ceriagrion tenellum*, *Leucorrhinia rubicunda*, *Aeshna juncea* or *Somatochlora arctica* are restricted to the area around the villages of Brunssum and Schinveld. Species such as *Ischnura elegans*, *Coenagrion puella*, *Aeshna cyanea* and *Libellula depressa*, which show no preference for a particular type

of water, are widespread and abundant in Southern Limburg. Species which prefer running waters are found in the valleys of the river Meuse and the larger brooks, such as Geul and Gulp. Some dragonfly habitats, such as pools and limestone quarries, are discussed separately. Several pools in the Mergelland (the southwestern part of Southern Limburg) have disappeared and many are in a deplorable state due to lack of maintenance. The most common species breeding in such pools are Blue Hawker, Common Bluetail and Broad-bodied Chaser. Limestone quarries are of great importance for dragonflies. The sheltered situation and the continuing limestone extraction provide a special and warm habitat. Most of the dragonfly species recorded there, like *Ischnura pumilio*, *Orthetrum brunneum* and *O. coerulescens* need the dynamic environment found in these quarries." 14710. Akamatsu, F.; Toda, H. (2011): Aquatic subsidies transport anthropogenic nitrogen to riparian spiders. *Environmental Pollution* 159(5): 1390-1397. (in English) ["Research highlights: * d15N of aquatic insects increases downstream with anthropogenic nitrogen inputs. * d15N of riparian spiders increases with a high dietary proportion of aquatic insects and smaller spider body size. * The aquatic subsidies transport anthropogenic nitrogen to smaller riparian spiders downstream. Stable nitrogen isotopic composition (d15N) of aquatic biota increases with anthropogenic N inputs such as sewage and livestock waste downstream. Increase in d15N of riparian spiders downstream may reflect the anthropogenic pollution exposure through predation on aquatic insects. A two-source mixing model based on stable carbon isotopic composition showed the greatest dependence on aquatic insects (84%) by horizontal web-building spiders, followed by intermediate (48%) and low (31%) dependence by cursorial and vertical web-building spiders, respectively. The spider body size was negatively correlated with the dietary proportion of aquatic insects and spider d15N. The aquatic subsidies transported anthropogenic N to smaller riparian spiders downstream. This transport of anthropogenic N was regulated by spider's guild designation and body size. Smaller spiders assimilate anthropogenic nitrogen through the predation on aquatic subsidies." (Authors) The diet includes *Sympetrum frequens*, *S. infuscatum*, *S. pedemontanum*.] Address: Akamatsu, F., Department of Environmental Sciences, Shinshu University, 3-1-1 Asahi, Matsumoto, Nagano 390-8621, Japan

14711. Akkermans, R.W.; Geraeds, R.P.G. ; Schaik, V.A. van (2011): The expansion of the Broad Scarlet in the Dutch province of Limburg. *Natuurhistorisch Maandblad* 100(7): 113-118. (in Dutch, with English summary) ["Although the first Broad scarlet (*Crocothemis erythraea*) in Limburg was seen as early as 1968, it took until 1995 before the second specimen was spotted in the province. In that year, a number of specimens were

observed at several locations. The site with the largest number of observations at the time was the Doort nature reserve near Echt in the central part of Limburg. From 1995 to 2006, the Broad scarlet expanded its range over the whole of the province, although the rate of expansion was low in the first few years, with rising numbers of observations in a few 1x1 kilometre grid squares. From 1998 to 2002, the species expanded to other grid squares from a few core areas where it was seen every year. Between 2003 and 2005, numbers of the Broad scarlet grew slowly and the species spread across further grid squares. But in 2006, the number of observations exploded and there was a major expansion in terms of grid squares. Since that year, the Broad scarlet has colonised the whole province of Limburg and is now a rather common species. The whole colonisation process took about 12 years. Although there have been rumours about the species producing two generations a year, there is still no proof of this. The existence of two peaks in the flight period diagram suggests a second generation, but further investigation is required." 14712. Cannings, R. (2011): Hanging from a Leaf. In: Li, J.L. & M.T. Barbour (eds.); B. Boonsoong (ill.): Wading for bugs. Exploring streams with the experts. Oregon State University Press. ISBN 978-0-87071-608-9. 176 pp: 103-107. (in English) ["In Wading for Bugs, nearly two dozen aquatic biologists share their memorable encounters with stream insects. The contributors, based primarily in North America, work in diverse environments – from arctic to desert, from mountain streams to river valleys. They represent a wide range of expertise as authors of standard field texts, leaders in biomonitoring and assessment programs, directors of major laboratories, and specialists in aquatic ecology and taxonomy. The writings in Wading for Bugs allow readers to experience – through the eyes of the scientists – what it's like to study stream insects and to make discoveries that could help develop biological indicators for stream health. General summaries introduce each insect order. Elegant insect drawings accompany each story, along with morphological, life history, and habitat information for each species or family. Wading for Bugs will appeal to general readers as well as students, naturalists, and outdoor enthusiasts curious about streams and the insects that live in them." (Publisher) In chapter 18, Rob Cannings contributes his story on *Stylurus olivaceus*.] Address: <http://osupress.oregon-state.edu/book/wading-for-bugs>

14714. Evans, M.V. (2011): The relative strength of top-down and bottom-up trophic dynamics in the context of habitat isolation. Senior Honors Thesis. Washington University in St. Louis, Environmental Studies Program: 31 pp. (in English) ["Habitat isolation is rapidly increasing, due, in part, to habitat fragmentation. While isolation's effects on species richness, genetic diversity, predator:prey ratios, etc. have been well studied, little is known about isolation's effect on trophic dynamics. Isolation can potentially alter both top-down and bottom-up dynamics through its effects on local processes, such as predation and herbivory, that influence trophic dynamics. In order to investigate the impact of isolation on trophic dynamics, I conducted an experiment in aquatic mesocosms manipulating isolation and bottom-up and top-down dynamics, through the addition of nutrients and fish, respectively. The strengths of topdown and bottom-up dynamics were differentially affected by isolation. Generally, isolation weakened top-down processes relative to bottom-up processes, which were not significantly altered by isolation. I found predator communities to consist of less efficient predators at high isolation, while herbivore community composition was relatively unaffected by isolation. This suggests that a possible mechanism behind the differential shift in trophic dynamics over isolation may be a change in predator community composition. My experiment illustrated that isolation could indirectly affect communities through its effects on trophic dynamics and suggests further that top-down and bottom-up dynamics do not respond equally to isolation." (Author) Taxa - including Odonata - are treated at the order level.] Address: not stated

14715. Geraeds, R.; Hermans, J.; Ramaker, A. (2011): De Gaffelwaterjuffer opnieuw in Limburg gevonden - Dainty bluet rediscovered in Limburg. *Natuurhistorisch Maandblad* 100(3): 41-45. (in Dutch, with English summary) ["The Netherlands; "*Coenagrion scitulum*, which has a Holomediterranean distribution, is slowly expanding its range northward. This damselfly was first found in the Netherlands in 2003, near the village of Tegelen in the province of Limburg. Since no other specimens could be traced in this area, this is likely to have been a migrating individual from a nearby population. The next Dutch reports of the species came from the coastal region in the province of Zeeland, where the species has been spotted each year since 2007. On 21 May 2010, the Dainty bluet was rediscovered in Limburg, this time in the southern part of the province. The specimen was a freshly emerged male. During the following days, Dainty bluets were seen in large numbers, including tandems and emerging damselflies, at a pond in a meadow, making it clear that this pond hosts a population. The discovery of this population

fits in with the increase of the Dainty bluet in Northwestern Europe. In France, the species is expanding northward, and recently populations were discovered in Belgium, Germany and Luxembourg. The Dainty bluet prefers sunny still waters with rich aquatic vegetation such as water-milfoils (*Myriophyllum*) and hornworts (*Ceratophyllum*). Most water bodies where it occurs are sheltered by relatively high vegetations, such as those consisting of Common reed (*Phragmites australis*) and Broadleaf cattail (*Typha latifolia*). The submersed vegetation in the pond in Southern Limburg is dominated by Rigid hornwort (*Ceratophyllum demersum*), while other species include Floating pondweed (*Potamogeton natans*), Sago pondweed (*P. pectinatus*), Common duckweed (*Lemna minor*) and Greater duckweed (*Spirodela polyrhiza*). The pond is sheltered by a hedgerow." (Authors)] Address: Geraeds, R.P.G., Bergstraat 70, 6131 AW Sittard, The Netherlands

14716. Guillermo-Ferreira, R.; Vilela, D.S. (2011): Female courtship in *Mnesarete lencionii*? *Agrion* 16(1): 14. (in English) [Verbatim: During our field research at the Ecological Reserve of the "Clube de Caça e Pesca Itororó de Uberlândia", Uberlândia, State of Minas Gerais, Brazil (15°57'S, 48°12'W; altitude 863 m; 640 ha), we collected and observed specimens of the rare *Mnesarete lencionii* Garrison, 2006. The males we observed had the blue-grey-black colouration pattern and hyaline wings described by Garrison (2006). However, although females presented the body colour described, their wings were not hyaline but had a reddish-brown spot at the base and ivory pterostigma. At first glance, we thought *M. lencionii* females were *Hetaerina* males. Only after capturing them we noticed they were females, identified later as *M. lencionii*. Thus, in our curiosity, we made some behavioural observations. The observations presented here are from three males and seven females. Males always remained perched, paying no attention to females around. Females displayed a curious behaviour. They approached the male and perched in front of him and started to make short hovering flights and then returned to the male's perch. Such behaviour may be considered a visual signal for intersexual communication (Corbet 1999) or even a display used to invite males to mate (Abbott 2005). Considering that red spots are used in sexual attraction and courtship by male calopterygids (reviewed by Cordoba-Aguilar & Cordero-Rivera 2005), we wonder if a red spot on a female wing, combined with hovering flights, can eventually have a role in female courtship and male mate choice. We also observed females fighting each other near the male. Apparently, this population had a female biased sex ratio. This fact should indeed promote female-female competition for males. Since this species is rare and we have seen only ten individuals in three years, we provide this note as a suggestion for further studies if someone finds a better population to investigate.] Address: Guillermo-Ferreira, R., Departamento de Biologia, Faculdade de Filosofia, Ciências e Letras de Ribeirão Preto, Universidade de São Paulo, Ribeirão Preto, SP, Brazil. E-mail: rhainerguillermo@yahoo.com.br

14717. Hutchings, G.; Halstead, D. (2011): Dragonflies and damselflies in the hand: An identification guide to boreal forest odonates in Saskatchewan and adjacent regions. *Nature Saskatchewan Special Publication* 29: 158 pp. (in English) ["These aims are ably met in an attractive package that includes about 200 photographic images and over 40 pages of drawings and keys. The clearly written text uses the necessary minimum of technical terms, all well-explained when introduced and included in a glossary. The book's scope is an ecological region, the western boreal forest, rather than a geopolitical entity such as Saskatchewan; it thus covers a broad swath of some of the less populous portions of the three Prairie Provinces. A map clearly outlines the main ecozones within this region. There are no individual distribution maps, but notes in the species accounts give a sense of any trend to north or south, east or west. The region is home to 13 damselfly and 36 dragonfly species (collectively, odonates), plus a number of what the authors call "fringe species" – mostly insects with more southerly or easterly ranges that peter out at the edge of the boreal forest. The total of 49 regular species is roughly half the Manitoba provincial list, and includes one western dragonfly (the Pale Snaketail) that has yet to be recorded in Manitoba. Introductory sections inform us about the life cycle of odonates, their roles as both predators and prey in the boreal ecosystem, and their adaptation to a harsh regime of long winters and brief summers. General tips on observation, identification, and photography are provided. Five landscape photographs show examples of boreal wetland types, and there is a representative photo of exuviae, the larval casings that remain after metamorphosis. The identification to species of such remains is a challenge beyond the book's scope. Each species account has three sections: a description to help with identification details, a brief statement of the preferred habitat, and notes on similar species, relative rarity or abundance, distribution, or behaviour. Illustrations typically show hand-held specimens, carefully posed with key identifying features in sharp focus against an unobtrusive background. There are also many photographs of unrestrained insects, plus closeups or crops of key anatomical details. The latter are mostly grouped on separate pages, with clear cross-referencing from the species accounts. A three-page bibliography provides guidance for further reading, and there is a helpful seasonal key to flight periods. For anyone spending time north of the Winnipeg River or aspen parkland regions, this book will be an excellent field companion. For anyone whose focus is a little farther south, or who simply can't resist good nature books with Manitoba content, it will be a valuable addition to the bookshelf. It is good to see *Nature Saskatchewan's* long tradition of natural history publication progressing so well into the 21st century." (review: Peter Taylor; <http://www.naturemanitoba.ca/sites/default/files/NMNews-NovDec-2011-web2.pdf>)] Address: Available from *Nature Saskatchewan*: email info@naturesask.ca, call (306) 780-9273 or mail 206 - 1860 Lorne St., Regina, SK S4P 2L7, Canada

14718. Ige, O.; Adeyemi, C.; Ogunfolakan, A.; Ayansola, A.; Olayemi, A.; Taiwo, Y.; Olayiwola, M.; Oyelade, J. (2011): An Inventory of the geological, biological and cultural resources on Ufe-Oke Hill, Idanre, southwestern Nigeria. *Natural Resources* 2: 180-190. (in English) ["Idanre, which represents a unique topographical landscape within southwestern Nigeria, is being proposed to the United Nations Educational Scientific and Cultural Organization (UNESCO) for designation as a world heritage site. In line with this, we conducted a survey to document the rich geological, biological and cultural resources contained within the Ufe-Oke section of Idanre Hills. Our geological inventory revealed two major rock types, older porphyritic granite and fine grained granite, in addition to other minerals. We identified insects belonging to 174 species while fishes from 4 species were collected. Mammals belonging to 13 species were identified through trapping, sightings and signs, although an even greater variety was inferred from interviews with hunters and visits to local fetish markets. Patterns concerning how these biological taxa are distributed altitudinally along Ufe-Oke Hill are discussed. In addition, in the quarters within Ufe-Oke representing the ancient city of Idanre, we characterized about 200 pieces of anthropological material, which included pottery shards, beads, chinaware, brass bangles and ancient metal coins. We also identified various other major features of archeological interest. Finally we offer recommendations, in the light of our findings, concerning how the variety of resources catalogued in this study can be effectively harnessed while sustaining at the same time the environmental integrity of this site, which offers the greatest opportunities and potential for tourism." (Authors) Insects including Odonata are treated at the order level.] Address: Ige, O., Natural History Museum, Obafemi Awolowo University, Ile Ife, Nigeria. Email: oige@oauife.edu.ng

14719. Kazanci, N. (2011): Characteristics of Odonata (Insecta) fauna of Köyceğiz-Dalyan Special Environmental Protected Area (SEPA) and its conservation. *Review of Hydrobiology* 4(2): 87-97. (in English, with Turkish summary) [The Odonata fauna of Köyceğiz-Dalyan SEPA (Mugla province, Turkey) comprises 28 species. From the conservation point of view, *Calopteryx splendens intermedia*, *Caliaeschna microstigma*, *Gomphus flavipes lineatus*, *Anax immaculifrons* and *Lindenia tetraphylla* are most interesting.] Address: Kazanci, Nilgün, Hacettepe University, Science Faculty, Biology Department, Hydrobiology Section, Beytepe, Ankara, Turkey. 14720. Labandeira, C. (2011): Silurian to Triassic plant and hexapod clades and their associations: new data, a review, and interpretations. *Arthropod Systematics & Phylogeny* 64(1): 53-94. (in English) ["A preliminary evaluation of hexapod herbivore damage from selected compression and permineralized biotas from the 220 million-year Late Silurian to Late Triassic interval has revealed many previously unknown patterns of hexapod herbivore

use of vascular plants as well as detritivore and predator associations. Data was collected from 48 distinctive hexapod herbivore damage types (DTs) from 21 mostly compression biotas, but with special emphasis on the Rlyinyne Chert (Early Devonian, ~ 408 Ma), Calhoun Coal (Late Pennsylvanian, ~ 303 Ma) and Molteno Formation (Late Triassic, ~ 226 Ma). These data indicate a two-phase herbivore colonization of land; later expansion of hexapod functional feeding groups (FFGs) initially in the Late Pennsylvanian wetland environments of equatorial Euramerica, and subsequently in Early Permian fluvial systems in the rest of Euramerica, Gondwana, and Cathaysia; the devastating end-Permian extinction; and subsequent rebound of those same FFGs during the ensuing Triassic. Modern-aspect herbivore, detritivore, and predator FFGs are present in Late Pennsylvanian canopied forests, and the full spectrum of all terrestrial FFGs are in place during the Late Triassic. Freshwater FFGs are delayed when compared to the terrestrial record, originating during the Permian, experiencing expansion during the Triassic, and reaching modern levels of all major trophic types during the Late Jurassic. A major conclusion is the omnipresence of convergence in FFGs throughout this interval and the spatiotemporally changing and ephemeral nature of plant hosts and their hexapod herbivore taxa." 14722. Lee, Y.H. (2011): Speciation with gene flow in island damselflies. M.Sc. thesis, Department of Life Sciences, Tokai University: 67 pp. (in English, with Chinese summary) ["Geographic isolation has been proposed as a major force in speciation. Allopatric mode of speciation emphasizes the prominent role of physical barriers and restriction of gene flow on population divergence. Under allopatric model, gene flow is considered as an impediment for speciation. The question of how much historical gene flow has occurred in diverged natural populations and species is largely unknown. In this study, we investigated the level of historical gene flow during the speciating process of two sibling species pairs of *Euphaea* damselflies, *E. formosa* + *E. yayeyamana* and *E. decorata* + *E. ornata*, using two mitochondrial and ten nuclear loci. The reconstructed species phylogeny based on *cox2* and *arr* genes indicated that *E. formosa* + *E. yayeyamana*, and *E. decorata* + *E. ornata*, are both valid sister species pairs. The results of multilocus analyses rejected the strict isolation model in *E. formosa* and *E. yayeyamana*, and *E. decorata* and *E. ornata*. Moderate to large

two directional gene flows were detected between *E. formosa* and *E. yayeyamana*, but there is little evidence of gene flow between *E. decorata* and *E. ornata*. The divergence time of *E. decorata* and *E. ornata* was estimated at approximately 0.511 Mya, which was more recent than the split of *E. formosa* and *E. yayeyamana* (1.145 Mya). We concluded that the model of speciation with gene flow best describe the observed sequence variation in *E. formosa* and *E. yayeyamana*, whereas the model of allopatric speciation without gene flow is more appropriate for *E. decorata* and *E. ornata*." (2011): Macroinvertebrate colonization of two different tree species leaf packs (native vs. introduced) in a Mediterranean stream. *Journal of Freshwater Ecology* 26(4): 495-505. (in English) ["Allochthonous leaf litter from riparian vegetation represents the main energy source in small lotic systems, where canopy limits autochthonous primary production. In this study, leaf packs of two tree species (the native *Salix neotrichia* and the introduced *Populus x canadensis*) were positioned in the Fardes Stream (southern Spain) to analyze the macroinvertebrate colonization. On two dates, leaf packs were removed, and colonizing macroinvertebrates were collected and identified; at the same time, Surber samples were collected to characterize the riverbed macroinvertebrate coenosis. Leaf packs attracted rich and varied communities of benthic macroinvertebrates, with an increase of the abundance of most taxa over time. No significant differences were found between the colonizing communities of the two leaf types. Some macroinvertebrate species showed a preference for leaf packs, probably due to trophic or hydrologic factors. Considering functional feeding groups, increases in shredders and scrapers and decreases in predators and filterers were detected over time, while collector-gatherers almost did not change in abundance." (Authors) Taxa, including Odonata, are treated at the family level.] Address: Peralta-Maravera, I., Depto de Biología Animal, Facultad de Ciencias, Univ. de Granada, Campus Fuentenueva s/n, 18071, Granada, Spain. 14731. Bryan, A.L.; Hopkins, W.A.; Parikh, J.H.; Jackson, B.P.; Unrine, J.M. (2012): Coal fly ash basins as an attractive nuisance to birds: Parental provisioning exposes nestlings to harmful trace elements. *Environmental Pollution* 161: 170-177. (in English) ["Birds attracted to nest around coal ash settling basins may expose their young to contaminants by provisioning them with contaminated food. Diet and tissues of Common Grackle (*Quiscalus quiscula*) nestlings were analyzed for trace elements to determine if nestlings were accumulating elements via dietary exposure and if feather growth limits elemental accumulation in other tissues. Arsenic, cadmium, and selenium concentrations in ash basin diets were 5× higher than reference diets. Arsenic, cadmium, and selenium concentrations were elevated in feather, liver, and carcass, but only liver Se concentrations approached levels of concern. Approximately 15% of the total body burden of Se, As, and Cd was sequestered in

feathers of older (>5 days) nestlings, whereas only 1% of the total body burden of Sr was sequestered in feathers. Feather concentrations of only three elements (As, Se, and Sr) were correlated with liver concentrations, indicating their value as non-lethal indicators of exposure. Highlights: * We examined elemental uptake by grackle nestlings associated with coal ash basins. *Diet of ash basin nestlings had higher levels of Se, As, and Cd than control nestlings. *Se, As, Cd, and Sr concentrations of ash basin nestling tissues were elevated. *Only Se in nestling liver approached published levels of concern. *Nestling feathers sequestered >15% of the total body burden of Se, As, and Cd." (Authors) The paper includes a passing reference to Odonata as diet of the nestlings] Address: Bryan Jr., A.L., Savannah River Ecology Laboratory, P.O. Drawer E, Aiken, SC 29803, USA. (2012): 170 Years of "Lock-and-Key": Genital morphology and reproductive isolation. *International Journal of Evolutionary Biology* Volume 2012, Article ID 247352, doi:10.1155/2012/247352: 10 pp. (in English) ["The divergent genital morphology observed among closely related animal species has long been posited as a mechanism of reproductive isolation. Despite the intuitive appeal that rapidly evolving genitalia might cause speciation, evidence for its importance—or even its potential—in reproductive isolation is mixed. Most tests of genital structural isolation between species often fail to find convincing evidence that differences in morphology prevent copulation or insemination between species. However, recent work suggests that differences in genital morphology might contribute to reproductive isolation in less obvious ways through interactions with sensory mechanisms that result in lowered reproductive fitness in heterospecific matings. In this paper, I present a brief history of the "lock-and-key" hypothesis, summarize the evidence for the involvement of genital morphology in different mechanisms of reproductive isolation, discuss progress in identifying the molecular and genetic bases of species differences in genital morphology, and discuss prospects for future work on the role of genitalia in speciation." (2012): The morphometry of male and female adults of the scarce emerald damselfly (*Lestes dryas* Kirby, 1890). *Studia odonatol. hung.* 14: 5-25. (in Hungarian, with English summary) ["We found very few detailed information about the morphometry of *Lestes dryas* on world-wide and on Hungarian basis too. Here we would like to provide more information concerning this species furthermore explore the variation of the examined traits and compare the two sexes by traits. The study based on body and wing traits of male and female adults which were collected in populations of north-eastern Hungary. According to our results males had significantly larger body than females, however other traits (measures on the head, leg and wings) seemed to be smaller. The traits of the anal appendages had a greater variation, than other body traits. The sizes of the wings had smaller variation than the number of cross veins and the cells. The principal component analysis could divide the sexes based on the body traits, but in the case of the wing traits the convex hulls overlapped in a small compass. The discriminant analysis split the two sexes based on both trait groups. According to the linear regression analysis the total body length showed the maximal number of correlations in both sexes." (in English) [Verbatim: One late afternoon in the fall of 2011, I stopped by the North Roosevelt trap, a popular birding spot in east central New Mexico (aka the "Melrose Trap", 10 miles west of Melrose in Roosevelt County). The trap is a stand of several large cottonwoods among a stand of poplar trees (some 60-70 ft. high) totalling about 2 acres. There is a single 14 ft. diameter pump-fed cattle tank as the only source of standing water. There are usually several (<10) dragonflies hanging

around the tank; Flame Skimmer (*Libellula saturata*), Roseate Skimmer (*Orthemis ferruginea*), Common Green Darner (*Anax junius*), Twelve-spotted Skimmer (*Libellula pulchella*), and Blue-faced Darner (*Coryphaeschna adnexa*) have been seen at various times. There was an emergence of a late ants in progress throughout the area, but I am not sure of the species. Around the open areas of the trap, I observed hundreds of dragonflies (my estimate of the total at the time was about 2000). All identified individuals were Common Green Darners, and I didn't see any individuals that I thought were a different species. A flying ant would not get far off the ground before a dragonfly had scooped it up. Since there are no large bodies of water in the area, I'm guessing these must have comprised a long-distance migrating swarm, something I have never encountered before. I appear to have left this out of my birding notes, so I have no precise date.] Address: Oldenettel, J.R., Socorro, New Mexico, USA. E-mail: Borealowl@aol.com

14747. Bransky, J.W.; Dorn, N.J. (2013): Prey use of wetland benthivorous sunfishes: ontogenetic, interspecific and seasonal variation. *Environmental Biology of Fishes* 96(12): 1329-1340. (in English) ["The intensity of

competitive interactions between fishes is partly determined by prey use and ontogenetic niche shifts. In a wetland where distinct habitat shifts are missing we compared prey use of three generalist benthivorous sunfishes to look for evidence of ontogenetic, interspecific, and "seasonal" variation in prey composition. Diet analysis revealed evidence of diet ontogeny in warmouth (*Lepomis gulosus*, 30–152 mm standard length, SL), but not in bluespotted sunfish (*Enneacanthus gloriosus*, 30–47 mm SL) or dollar sunfish (*Lepomis marginatus*, 30–60 mm SL). Bluespotted and dollar sunfishes consumed small dipteran and amphipod prey and had similar diets in both seasons suggesting a potential for strong interspecific competition. In the dry season, warmouth shifted from using smaller insect prey to larger decapod and fish prey with increasing size. This shift to prey types that were little used by the other species reduced dietary niche overlap with the other sunfishes. After drought and re-flooding (in the wet season), decapods and small fish were less abundant in the wetland and the warmouth ontogenetic shift was less distinct. When matched for gape width, prey composition differed between warmouth and both dollar and bluespotted sunfishes in the wet season, suggesting differences in sunfish foraging modes, but prey use differences were less clear in the dry season when prey were abundant. Both warmouth ontogenetic diet shifts and seasonal variation in prey use (probably mediated by prey abundance) had strong influences on diet overlap and therefore the potential for intra- and interspecific competition between sunfishes in this wetland ecosystem." 14749. Crotti, M. (2013): Digenetic Trematodes: an existence as parasites. Brief general overview. *Microbiologia medica* 28(2): 97-101. (in English) ["Digenea is a wide and diverse group of trematodes, whose members are able to parasitize all classes of vertebrates, and several groups of invertebrates. While the usual life-cycle involves three hosts, a great number of species has evolved to increase or to reduce the number of hosts during development, in order to be more successful in their

ecological niche. Differently from other trematodes, digenetic flukes can infect humans, and this process can cause severe diseases like schistosomiasis, which infects around 200 million people worldwide. Finally, digenetic trematodes are not only a threat to humans' health, but also to the economy, causing millions of dollars losses in activities such as aquaculture and animal husbandry. ... Some members of the *Halipegus* genus have been observed to infect four hosts during their development. Zelmer, et al. (45) have described the complex development of *Halipegus occidualis*. This species is a parasite of green frogs, and it is found in North America. The eggs are expelled by frogs and are ingested by snails. Once the cercaria leaves the mollusc, it penetrates the secondary intermediate host, a crustacean (ostracods). The crustaceans are a food source for dragonfly larvae, the third intermediate host. However, Zelmer, et al (45) found out that the insect larva is not a physiological requirement for the further development of the trematode, but instead is an ecological necessity in order for the trematode to reach the definitive host (green frogs do not feed on ostracods, but do feed on dragonfly larvae). [Zelmer DA, Wetzel EJ, Esch GW. The role of habitat in structuring *Halipegus occidualis* metapopulations in the green frog. *Journal of Parasitology*. 1999; 85: 19-24.]" (Author)] Address: Crotti, M. (2013): Broad-scale patterns of invertebrate richness and community composition in temporary rivers: effects of flow intermittence. *Ecography* 37(1): 94-104. (in English) ["Temporary rivers are increasingly common freshwater ecosystems, but there have been no global syntheses of their community patterns. In this study, we examined the responses of aquatic invertebrate communities to flow intermittence in 14 rivers from multiple biogeographic regions covering a wide range of flow intermittence and spatial arrangements of perennial and temporary reaches. Hydrological data were used to describe flow intermittence (FI, the proportion of the year without surface water) gradients. Linear mixed-effects models were used to examine the relationships between FI and community structure and composition. We also tested if communities at the most temporary sites were nested subsets of communities at the least temporary and perennial sites. Taxon richness decreased as FI increased and invertebrate communities became dominated by ubiquitous taxa. The number of resilient taxa (with high dispersal capacities) decreased with increased FI, whereas the number of resistant taxa (with adaptations to desiccation) was not related to FI. Riverspecific and river-averaged model comparisons indicated most FI-community relationships did not differ statistically among rivers. Community nestedness along FI gradients was detected in most rivers and there was little or no influence of the spatial arrangement of perennial and temporary reaches.

These results indicate that FI is a primary driver of aquatic communities in temporary rivers, regardless of the biogeographic species pool. Community responses are largely due to resilience rather than resistance mechanisms. However, contrary to our expectations, resilience was not strongly influenced by spatial fragmentation patterns, suggesting that colonist sources other than adjacent perennial reaches were important." 14752. Gilbreath, T.M.; Kweka, E.J.; Afrane, Y.A.; Githeko, A.K.; Yan, G. (2013): Evaluating larval mosquito resource partitioning in western Kenya using stable isotopes of carbon and nitrogen. *Parasites & Vectors* 12;6:353. doi: 10.1186/1756-3305-6-353.: 17 pp. (in English) ["Background: In sub-Saharan Africa, malaria, transmitted by the *Anopheles* mosquito, remains one of the foremost public health concerns. *Anopheles gambiae*, the primary malaria vector in sub-Saharan Africa, is typically associated with ephemeral, sunlit habitats; however, *An. gambiae* larvae often share these habitats with other anophelines along with other disease-transmitting and benign mosquito species. Resource limitations within habitats can constrain larval density and development, and this drives competitive interactions among and between species. Methods: We used naturally occurring stable isotope ratios of carbon and nitrogen to identify resource partitioning among co-occurring larval species in microcosms and natural habitats in western Kenya. We used two and three source mixing models to estimate resource utilization (i.e. bacteria, algae, organic matter) by larvae. Results: Laboratory experiments revealed larval $\delta^{13}\text{C}$ and $\delta^{15}\text{N}$ composition to reflect the food sources they were reared on. Resource partitioning was demonstrated between *An. gambiae* and *Culex quinquefasciatus* larvae sharing the same microcosms. Differences in larval $\delta^{13}\text{C}$ and $\delta^{15}\text{N}$ content was also evident in natural habitats, and *Anopheles* species were consistently more enriched in $\delta^{13}\text{C}$ when compared to culicine larvae. Conclusions: These observations demonstrate inter-specific resource partitioning between *Cx. quinquefasciatus* and *An. gambiae* larvae in natural habitats in western Kenya. This information may be translated into opportunities for targeted larval control efforts by limiting specific larval food resources, or through bio-control utilizing competitors at the same trophic level. ... Dragonfly nymphs had an isotopic composition indicative of a pri-

marily anopheline diet. Although this result should be interpreted somewhat carefully since only three food sources were taken into account (*Cx. quinquefasciatus*, *An. gambiae* and *An. funestus*), studies suggest that culicine larvae may have a competitive advantage over anophelines when dragonfly nymphs are present in the habitat [2,31]. Our group reported a 70% reduction of *An. gambiae* s.s. larvae exposed to dragonfly nymphs, and used PCR to confirm the presence of *An. gambiae* DNA in the nymph gut content [21]. There may be other significant contributors to the nymph diet, but these resources would presumably occupy the same trophic level of the anophelines. Microcosm experiments with known predators and prey may help to evaluate the role of trophic structure in determining mosquito species success and habitat productivity." Martini, A.; Resende, D.M.C.; Ribeiro Silva, L.; Duarte, M.A. (2013): Distribuição espacial e temporal da fauna de invertebrados bentônicos na APA do município de Coqueiral, MG, com ênfase em Odonata. *Revista Brasileira de Zoociências* 15(1-3): 183-194. (in Portuguese, with English summary) ["Spatial and temporal distribution of benthic invertebrates fauna in APA of the municipality Coqueiral, MG, with emphasis on Odonata. The benthic invertebrates are a diverse group of organisms that inhabit both lentic and lotic environments and have an important role in the aquatic ecosystem dynamics, and its use for the evaluation of impacts on aquatic environments, widely recommended. Among the benthic invertebrates, highlight the Odonata use for verification of environmental quality. The present study had as objective to know the spatial and temporal distribution of benthic invertebrates fauna in the stream of Ermo, in the APA of the municipality - Coqueiral, MG, with emphasis on Odonata, and infer on the local environmental conditions. Samples were collected during the rainy season (February, 2007) and dry (August, 2007) at seven sites along the stream. First were measured and recorded abiotic variables: water temperature with a thermometer, depth using a graduated ruler and the dissolved oxygen content with oximeter. Later sediments were collected for analysis of benthic invertebrates, using a Surber sampler. For Anisoptera were identified: *Dythemis*, *Nanothemis*, *Octogomphus* and *Progomphus* and for Zygoptera: *Argia*. The Jaccard analysis results showed a higher similarity between points 2 and 3 grouped due to the similarities of physic-chemical parameters, mainly temperature and dissolved oxygen recorded in the stream and a separation of the points 5 and 7. Studies about Odonata fauna are needed due to the great potential bioindicator that these organisms have, mainly because of its wide distribution." 14757. Nilsson-Örtman, V.; Stoks, R.; De Block, M.; Johansson, F. (2013): Latitudinal patterns of phenology and age-specific thermal performance across six Coenagrion damselfly species. *Ecological Monographs* 83: 491-510. (in English) ["Using a combination of computer simulations and laboratory experiments we test if the thermal sensitivity of growth rates change during ontogeny in damselfly larvae and if these changes can be predicted based on the natural progression of average temperature or thermal variability in the field. The laboratory experiment included replicated species from Southern,

Central and Northern Europe. Although annual fluctuations in temperature represent a key characteristic of temperate environments, few studies of thermal performance have considered the ecological importance of the studied traits within a seasonal context. Instead, thermal performance is assumed to remain constant throughout ontogeny and reflect selection acting over the whole life cycle. The laboratory experiment revealed considerable variation among species in the strength and direction of ontogenetic performance shifts. In four species from Southern and Central Europe, reaction norms were steepest during early ontogeny, becoming less steep during later ontogenetic stages (indicative of low-temperature acclimation). In one Northern European species, the slope of reaction norms did not change during ontogeny. In the other North European species, reaction norms became steeper during ontogeny (indicative of high-temperature acclimation). We had expected high-latitude species to show strong low-temperature acclimation responses, because they have a short flight season and inhabit a strongly seasonal environment. Instead, we found the reversed pattern: low-latitude species displayed strong low-temperature acclimation responses and high-latitude species displayed weak, or even reversed, acclimation responses to low temperatures. These findings suggest that low-temperature acclimation may be less beneficial and possibly more costly in habitats with rapid seasonal transitions in average temperature. We conclude that thermal performance traits are more dynamic than typically assumed and caution against using results from single ontogenetic stages to predict species' responses to changing environmental conditions." MSc. thesis, University of Ostrava, Faculty of Science, Biology / Systematic Biology and Ecology: (in Czech, with English summary) ["This thesis is focused on the effects of the parasitoids on reproductive lifestyle strategy of the damselfly of Lestidae family. Thesis describes the influence of parasitoidism on the unusual underwater egg-laying strategy in damselfly species. Theoretical part of the thesis is concerned on the issues of literature focused on dragonflies' mating, male's guarding for females, underwater oviposition, parasitoids, water parasitoids and the host-parasitoid interactions. The dates have been taken since 2010 to 2012 on the locality of botanical garden and arboretum of Štramberk (49° 35'

19.57°N 18° 7' 29.68"E) and the locality of the slate quarry ?Na Peklách? on Štramberk (49°34'52.093"N 18°6'52.509"E). The research has been taken at the same time and was focused on the endophytical under-ater egg-laying. Eggs have been tested for presence of parasitoids and for total eggs mortality in relation to water surface. Eggs were always laid on the leafless plants with a circular diameter and with their roofs under the water surface. Plants containing eggs there were *Equisetum variegatum* (Equisetaceae), *Schoenoplectus lacustris* (Cyperaceae) and *Juncus effusus* (Juncaceae). In three years of research, 8674 eggs were checked under a microscope. The rate of parasitoidism on eggs was 13,05 % above the water surface and 6,56% under it. The eggs' mortality was 18,86 % above the water surface and 21,4 % under it. Total rate of mortality is higher under the water surface then above it, which can be explained by many factors." (2013): Can a competitive neural network explain selective attention in insect target tracking neurons?. *Neural Engineering (NER)*, 2013 6th International IEEE/EMBS Conference, San Diego, CA, USA, 6-8 Nov. 2013. doi: 10.1109/NER.2013.6696081. URL: <http://ieeexplore.ieee.org/stamp/stamp.jsp?tp=&arnumber=6696081&isnumber=6695843>: 903-906. (in English) ["Small target motion detecting (STMD) neurons in the dragonfly brain (*Hemicordulia tau*) are neural correlates of a highly-specialized and ethologically-significant feature detection function, and the recent discovery of selective attention in STMDs has clear implications for the ability of dragonflies to track and pursue one target from among several. We used a biophysically-plausible neural network model, based on competitive units fed by NMDA-type synaptic inputs and including lateral feedback inhibition, to model these attentional effects in numerical simulations. With appropriate forward gain, the model displays a winner-takes-all behavior that partially captures the selective attention documented in electrophysiological recordings from STMDs. It cannot, however, explain the full range of results that have now been observed in wide-field STMDs, in particular a bias toward attention to targets dependent on their traversal of continuous trajectories." 14762. Alcorlo, P.; Jimenez, S.; Baltanas, A.; Rico, E. (2014): Assessing the patterns of the invertebrate community in the marshes of Donana National Park (SW Spain) in relation to environmental factors. *Limnetica* 33(1): 189-204. (in English, with Spanish summary) ["The marshes of Donana (SW, Spain) are some of the largest and best preserved Mediterranean marsh areas represented in Western Europe. They are considered a hotspot of biodiversity, and as such receive protected-area status under two different systems of protected-area management. The importance of submerged macrophytes in the functioning of marsh ecosystems has been addressed in several studies. However, most of the animal biodiversity studies have been developed for vertebrates. Thus, the aims of this study are i) to assess the composition of the invertebrate community in the marsh of Donana (zooplankton and zoobenthos) in a set of sites representing the different habitats of the marsh in both clear and turbid water states; ii) to compare diversity among patches in different states (clear vs turbid water); and iii) to address the main environmental factors that have influenced their community structure and diversity. A total of 102 taxa were recorded. The highest abundance values were attained by cladocerans and ostracods, both microcrustaceans, and by dipteran insects. It was possible to distinguish different marsh environments characterised by patches of clear water, where the macrophyte beds contribute to an increase of the structural heterogeneity of the marsh, providing the invertebrates with shelter and food resources and subsequently influencing different invertebrate assemblages. Conductivity, soluble reactive phosphorus (SRP) and chlorophyll-a concentration were the environmental variables that influenced the presence of turbid patches, which showed lower macrophyte cover, diversity and richness values than those seen in the clear water patches. The relationship between diversity (H') and richness (S), suggested that processes related to species migration (i.e., hydrologic connection with other water bodies, flood duration, and dissemination of propagules) are the main constraints influencing the invertebrate community structure in the Donana marshes." (Authors). The list of taxa includes *Enallagma cyathigerum*, *Ischnura graellsii*, *Lestes viridis*, *L. sponsa*, *Aeshna cyanea*, *Anax parthenope*, *Sympetrum fonscolombii*, *S. meridionale*, and *Crocothemis erythraea*.] Address: Alcorlo, Paloma, Dept. 14765. Barwell, L.J.; Azaele, S.; Kunin, W.E.; Nick, J.B. (2014): Can coarse-grain patterns in insect atlas data predict local occupancy? *Diversity and Distributions* 20(8): 895-907. (in English) ["Aim: Species atlases provide an economical way to collect data with national coverage, but are typically too coarse-grained to monitor fine-grain patterns in rarity, distribution and abundance. We test the performance of ten downscaling models in extrapolating occupancy across two orders of magnitude. To provide a greater challenge to downscaling models, we extend previous downscaling tests with plants to highly mobile insect taxa (Odonata) with a life history that is tied to freshwater bodies for reproduction. We investigate the species-level correlates of predictive accuracy for the best performing model to understand whether traits driving spatial structure can cause interspecific variation in downscaling success. Location: Mainland Britain. Methods: Occupancy data for 38 British Odonata species were extracted from the Dragonfly Recording Network (DRN). Occupancy at grains . 100 km² was used as training data to parameterize ten downscaling models. Predicted occupancy at the 25, 4 and 1 km² grains was compared to observed data at corresponding grains. Model predictive error was evaluated across species and grains. Main conclusions: The Hui model gave the most

accurate downscaling predictions across 114 species: grain combinations and the best predictions for 14 of the 38 species, despite being the only model using information at a single spatial grain. The occupancy.area relationship was sigmoidal in shape for most species. Species' distribution type and dispersal ability explained over half of the variation in downscaling predictive error at the species level. Species with a climatic range limit in Britain were poorly predicted compared with other distribution types, and high dispersal ability was associated with relatively poor downscaling predictions. Our results suggest that downscaling models, using widely available coarse-grain atlas data, provide reasonable estimates of finegrain occupancy, even for insect taxa with strong spatial structure. Linking species-level traits with predictive accuracy reveals general principles about when downscaling will be successful." 14766. Bateman, A.W.; Vos, M.; Anholt, B.R. (2014): When to defend: Antipredator defenses and the predation sequence. *The American Naturalist* 183(6): 847-855. (in English) ["Some authors have suggested that prey species stand to benefit most by defending as early as possible during predator-prey encounters, but species in nature employ antipredator defenses at various stages of interactions with their predators. Whether it is generally most advantageous to defend early or late during such encounters is an open theoretical question. We model conditions under which a prey species might evolve early or late defenses in response to predation. Adapting a two-prey, one-predator Rosenzweig-MacArthur system of differential equations, we analyse the effects of modified antipredator defenses (and their associated costs) on the ability of a new prey type to invade the one-prey, one-predator limiting system at equilibrium. We show that the outcome, in terms of invasion potential, is crucially dependent on the ratio of the prey's proportional population growth rate to the cost of predator encounters." B* 281 no. 1794 20141806: 6 pp. (in English) ["Organisms exhibit plasticity in response to their environment, but there is large variation even within populations in the expression and magnitude of response. Maternal influence alters offspring survival through size advantages in growth and development. However, the relationship between maternal influence and variation in plasticity in response to predation risk is unknown. We hypothesized that variation in the magnitude of plastic responses between families is at least partly due to maternal

provisioning and examined the relationship between maternal condition, egg provisioning and magnitude of plastic response to perceived predation risk (by dragonfly larvae: *Aeshna* spp.) in northern leopard frogs (*Lithobates pipiens*). Females in better body condition tended to lay more (clutch size) larger (egg diameter) eggs. Tadpoles responded to predation risk by increasing relative tail depth (morphology) and decreasing activity (behaviour). We found a positive relationship between morphological effect size and maternal condition, but no relationship between behavioural effect size and maternal condition. These novel findings suggest that limitations imposed by maternal condition can constrain phenotypic variation, ultimately influencing the capacity of populations to respond to environmental change." 14768. Borisov, S.N. (2014): Uses of traps on mountain pass Chokpak (Western Tien-Shan) for the number of migrating dragonflies (Insecta, Odonata). *Ornithological news of Kazakhstan and Middle Asia* 3: 167-171. (in Russian, with English summary) ["On the Chokpak pass in Western Tien-Shan (N 42°31' E 70°367) in the fall seasons of the 2008-10-th years using ornithological traps of Rybachinskii type the study of migratory dragonflies was conducted. The species of dragonflies caught in the traps were characterized by two different migration strategies. The first group consisted of the species with seasonal vertical migrations (*Sympetrum arenicolor*, *S. striolatum pallidum*, *S. meridionale*, *Aeshna mixta*), the second - of the species with translatitudinal migrations (*S. fonscolombii*, *Anax parthenope*, *A. ephippiger*). It was established that intensity of migration increased with the arrival of cold air fronts. Maximum of three thousand specimens fell in one trap per day. Visible flights of dragonflies near the surface of land were observed exclusively in the opposite south-west wind. It is assumed that the main migrations occur with the favourable wind at great heights and are not available to watch." 14770. Childress, J.M. (2014): Dragonflies and damselflies of Albemarle County, Virginia (Odonata). *Banisteria* 43: 28-39. (in English) ["The Odonata fauna of Albemarle County, Virginia has been poorly documented, with approximately 20 species on record before this study. My observations from 2006 to 2014, along with historical and other recent records, now bring the total species count for the county to 95. This total includes 64 species of dragonflies, which represents 46% of the 138 species known to occur in Virginia, and 31 species of damselflies, which represents 55% of the 56 species known to occur in Virginia. Also recorded here are the observed date ranges for adults of each species and some observational notes." (Author)] Address: Childress, J.M., 4146 Blufton Mill Road Free Union, Virginia 22940, USA

14771. Cooper, A. (2014): *Dragonflies: Fascinating facts about their life in the wild. Q&A Guide*, Stackpole Books: 112 pp. (in English) ["Got a question about dragonflies? This book has answers. *Dragonflies: A Q & A Guide* is a lively, illustrated guide for anyone looking to learn more about dragonflies and their lives in the wild. Easy-to-read format for readers looking to dip in or read straight through. Hundreds of questions posed and answered about the dragonfly's anatomy, history, and life cycle. Dozens of stunning colour photos of dragonflies in their habitats. Special sections on record-breaking dragonflies and the relationship between dragonflies and humans." (Publisher)]

14772. Cornejo, A. (2014): Estructura de la comunidad de macroinvertebrados dulceacuícolas en el área de concesión minera Cerro Petaquilla, Colón, Panamá. *Scientia (Panamá)* 24(2): 15-35. (in Spanish, with English summary) ["Aiming to characterize the structures of aquatic macroinvertebrate's community in Cerro Petaquilla Mining Project, we established 17 sampling stations, divided in two areas: Buffer Area (AA) and Direct Impact Area (AID), which were evaluated in September, 2007. We did three comparisons: between area, between stations and between microhabitats (backwaters and streams). We collected 8254 individuals from 119 taxa, showing a clear dominance by the groups of aquatic insects from Ephemeroptera group, following by Coleoptera, Trichoptera, Diptera, and, in a lower grade, Odonata. The genera *Thraulodes*, *Farrodes* and *Leptohyphes* represent the 31.34% from all reported individuals. The richness and abundance were higher in AA than AID, but these were non-significance differences. Conversely, the taxonomic richness and abundance were significantly varied between sampling stations and were lower in AA-01, AID-01 and AID-08. The taxonomic richness and abundance were significant varied between the evaluated microhabitat, being higher in streams than backwater. The sampling correctly represents the richness from the area, because all identified taxa are the 83% of the true richness from the area. The macroinvertebrate community was composed of organisms considered natural water indicators of good status. However, we show a negative impact from the mining activities on the pluvial ecosystem, caused by the removal of vegetation cover, which caused the increase of sedimentation levels and affect the macroinvertebrate's community structure in sampling stations AA-01, AID-01 and AID-08." (Author) Odonata are treated at genus level.] Address: Cornejo, A., Colección Zoológica Dr. Eustorgio Méndez, Instituto Conmemorativo Gorgas de Estudios de la Salud, Brazil. 14773. Cunha, R.; Fulan, J.A.; Rodrigues dos Santos, L. (2014): Influence of physical and chemical characteristics of water on spatial distribution of Odonata larvae associated with *Eichhornia crassipes* (Mart.) Solms in Uruapiara River, Madeira Basin, State of Amazonas, Brazil. *Estud Biol.* 2014 36(86): 36-42. (in Portuguese, with English summary) ["The objective of this study was to identify the odonates associated with *Eichhornia crassipes*, as well as investigate the main environmental variables that affect its spatial distribution in Uruapiara River, Amazonas, Brazil. The macrophytes were sampled in a hollow square with total area of 0.120m². The removal of the larvae was performed with washing plant with carbonated water. We evaluated the following variables: temperatures of the air and water, dissolved oxygen, pH, turbidity, total phosphorus and total nitrogen. We identified total of 73 larvae distributed in the families Libellulidae (64) and Coenagrionidae (9). Libellulidae was represented by *Erythemis*, *Micrathyria*, *Tauriphila* and *Nephepeltia* and Coenagrionidae by *Acanthagrion*

and *Oxyagrion*. A canonical correspondence analysis (CCA) showed that *Tauriphila* and *Coenagrionidae* were positively affected by the concentration of dissolved oxygen. *Nephepeltia* and *Oxyagrion* were negatively affected by increasing the dissolved oxygen. The study revealed that dissolved oxygen was the most significant factor in the distribution of larvae of Odonata in Uruapiara River." 14774. Czerniawska-Kusza, I.; Brożonowicz, A. (2014): Zoobenthos in post-exploitation reservoirs of marls and limestone in Opole Silesia. *Pol. J. Natur. Sc.* 29(4): 307-318. (in English) ["Large layers of carbonate rocks in Opole region for years serve as an exploitation material for the cement-lime industry. The mining results in numerous post-exploitation reservoirs, which biocenosis is poorly known. The objective of the study was to determine the effect of the environmental features on the distribution of macroinvertebrates and the community structure, and to present the significance of these water bodies for regional biodiversity. The research was carried out between June and November 2010 at eight reservoirs. Altogether 66 taxa were found, although only from 12 to 38 were recorded in particular reservoirs. The widespread and abundant were dipterans Chironomidae, dragonflies *Ischnura* sp. and *Coenagrion* sp., and mayflies *Caenis* sp. and *Cloeon* sp., especially numerous in charales meadows. Based on faunistic similarity, three groups of reservoirs were distinguished, which differed in size, character of a littoral zone and origin of waters (underground vs surface)." 14775. Dao, P.-g. (2014): The design and application of Odonata teaching modules. Dissertation, Institute of Entomology, National Taiwan University: (in Chinese, with English summary) ["This study mainly focuses on the application of dragonfly resource to the nature, living technology and environmental education, and discuss the affection of the five contents of environmental education on Fifth grade students. The objects of this study are two elementary schools in Taoyuan county of Taiwan, which are located in the country yard and city separately. The teaching model is classified into three subjects: biology of dragonfly, digital learning, dragonfly conservation, and the total number of courses are up to ten. The researchers coordinate with class teacher to evaluate the results of the study, and the results confirm with the assessment criteria of teaching model. We deliver the questionnaires, the application of dragonfly resource to the nature, living technology and environmental education, before and after the teaching course to test the affection of teaching model on the kids. There are five lines of conclusions of this study. First, both school kids are highly interested

and study effectively in the dragonfly teaching course model. Second, the dragonfly teaching course model can improve the five contents of environmental education in both schools. We also suggest that the framework of course design should be planned according to the profession of teacher, student interest and local insect materials. The teaching model could be expanded to other schools, and also adjusted by the class time and content." (Author)] Address: not stated

14778. Dolný, A.; Helebrandová, J.; Rusková, T.; Šigut, M.; Harabiš, F. (2014): *Ecological aspects of underwater oviposition in Lestes sponsa (Odonata: Lestidae)*. *Odonatologica* 43(3/4): 183-197. (in English) ["Underwater oviposition is a special subtype of endophytic oviposition and constitutes the predominant mode for certain species of Calopterygidae and Coenagrionidae. Very little is known about underwater oviposition in Lestidae and other dragonfly groups (e.g., Anisoptera). In July 2009, we recorded this specific behaviour in a population of *Lestes sponsa* in the Czech Republic (Moravia, Štřamberk). We subsequently studied the frequency of this phenomenon at regional (16 sites surveyed in an area of ca 1,260 km²) and local (proportions of eggs laid beneath and above the water's surface at three locations) levels. We examined further key environmental factors influencing underwater oviposition and certain ecological parameters (depth and time) of this behaviour in *L. sponsa*. The frequency of underwater oviposition on the regional scale was relatively low (< 20 %), but the frequency of this behaviour on a local scale was sometimes high. At those sites where underwater oviposition occurred, 4,759 (62 %) out of a total of 7,699 eggs were laid underwater. The main factors affecting underwater oviposition were transparency of the water column and type of

submerged vegetation. Ovipositing pairs spent on average 338 seconds under the water at an average depth of 20 cm. Further research should focus on the benefits of this specific oviposition tactic and especially egg mortality during overwintering." 14781. Folorunso, L A; Falaye, A E; Ajani, E K. (2014): *Predatory size of dragonfly (Palpopleura lucia (Drury, 1773) nymphs on guppy (Poecilia reticulata (Peters, 1859))*. *Journal of Fisheries and Aquatic Science* 9(6): 483-486. (in English) ["Attainment of adulthood by a young fish is a function of environment, competition, starvation, cannibalism and predation amongst other factors. Predators do not exhibit predatory qualities from birth, it has to grow over time before the qualities are expressed. Thus, the aim of this study was to determine minimum size of dragonfly (*Palpopleura lucia* (Drury, 1773)) nymphs (Naiads) that can predate on guppy (*Poecilia reticulata*) (Peters, 1859)) with a view to understanding predation in aquaculture. Guppies of 5-12 mm total length were introduced to naiads of varying lengths ranging from 2.00-10.00 mm over a 48 h period. Results obtained showed that naiads >6.00 mm were able to predate on guppies while those <5.5 mm co-habited with guppies without predation. This study thus concludes that aquaculture management practices can be geared towards eliminating naiads >6.00 mm, this will hopefully

assist farmers to optimize human and material resources expended in the control of naiads in aquaculture." (Authors)] Address: Folorunso, L.A., Samaru College of Agriculture, Division of Agricultural Colleges, Ahmadu Bello University, P.M.B 1058, Zaria, Nigeria

14786. Gaurav, S.; Jain, K.K. (2014): Numerical investigation of fluid flow and aerodynamic performance of a dragonfly wing section for Micro Air Vehicles (MAVs) applications. *International Journal of Innovation and Scientific Research* 9(2): 285-292. (in English) ["A comprehensive numerical simulation of fluid dynamics based study of a pleated wing section based on the wing of *Aeshna cyanea* has been performed at ultra-low Reynolds number corresponding to the gliding flight of these dragonflies in order to explore the potential applications of pleated airfoils for micro air vehicle applications. The simulation employs an unstructured triangular mesh based on finite volume discretization done in the ANSYS-14.0 using WorkBench14.0. Whenever, dragonfly wing interacts with the fluid (air taken), several forces and vibrations results out. These forces and vibrations cause certain changes over the dimensional structure over the wing and also influence the flows characteristics. A critical assessment of the computed results was performed. In this work, various flow patterns and aerodynamic performance of pleated airfoil has been obtained at ultra-low Reynolds numbers (2000-3000) at different angle of attacks (AOA) ranging from 0° to 15°. Also there effects on coefficient of Lift and Drag have been analysed. The simulations demonstrate that pleated airfoil produces higher lift and moderate drag that lead to an aerodynamic performance and hence pleated airfoil is an excellent choice for a fixed wing micro-air vehicle application." (Authors)] Address: Jain, K.K., Department of Mechanical Engineering, Sri Ram Institute of Technology, Jabalpur, Madhya Pradesh, India

14787. Goertzen, D.; Suhling, F. (2014): Central European cities maintain substantial dragonfly species richness – a chance for biodiversity conservation?. *Insect Conservation and Diversity* 8(3): 238-246. (in English) ["(1.) This study investigates whether cities have the potential of hosting high species diversity of dragonflies (Odonata), a target group in freshwater conservation. (2.) We reviewed the dragonfly fauna of 30 cities in Central Europe and analysed their species richness compared to the regional species pools in the hinterlands, i.e. estimated the amount of regional diversity represented in cities. In particular, we examined the occurrence of species of conservation concern at the European scale. (3.) Results revealed that 92.6% of all 81 Central European dragonfly species occurred in cities, as well as 85.7% of 14 species of conservation concern. As expected, assemblages of city species were subsets of the regional species pool and city species richness increased with regional species numbers. Some cities hosted the complete regional species pool. (4.) Ten species of conservation concern established autochthonous populations and six of them, such as *Aeshna viridis* and *Ophiogomphus cecilia*, were abundant at least in single cities. (5.) We conclude that there is good potential for cities to host high dragonfly diversity and even to promote species of conservation concern. To exploit this potential we recommend city planners to focus on the

needs of regionally characteristic species." (Authors)] Address: Goertzen, Diana, Institut für Geoökologie, Technische Universität Braunschweig, Langer Kamp 19c, 38106 Braunschweig, Germany. E-mail: d.goertzen@tu-bs.de

14788. Graf, J.F. (2014): Die Libellenfauna der Kykladeninsel Andros (Odonata). *Libellula* 33(1/2): 27-56. (in German, with English summary) ["The Odonate Fauna of the Cycladic Island of Andros – Data on adult dragonflies from the Cycladic island of Andros were collected between 2006 and 2013. On 289 visits 22 species were identified and 717 individual records were made at 48 different sites. Out of the 18 species already described from this island, all except *Lestes macrostigma* and *Coenagrion scitulum* could be observed again. Six additional species, *Sympecma fusca*, *Aeshna mixta*, *Anax parthenope*, *Anax ephippiger*, *Sympetrum fonscolombii*, and *Trithemis annulata* were observed for the first time on Andros. Altogether, 24 species have now been recorded for Andros, the highest number of all Cycladic islands." 14790. Hassall, C. (2014): Continental variation in wing pigmentation in *Calopteryx* damselflies is related to the presence of heterospecifics. *PeerJ* 2:e438; DOI 10.7717/peerj.438: 15 pp. (in English) ["Wing pigmentation in *Calopteryx* damselflies, caused by the deposition of melanin, is energetically expensive to produce and enhances predation risk. However, patterns of melanisation are used in species identification, greater pigmentation is an accurate signal of male immune function in at least some species, and there may be a role for pigment in thermoregulation. This study tested two potential hypotheses to explain the presence of, and variation in, this pigmentation based on these three potential benefits using 907 male specimens of *Calopteryx maculata* collected from 49 sites (34 discrete populations) across the geographical range of the species in North America: (i) pigmentation varies with the presence of the closely related species, *Calopteryx aequabilis*, and (ii) pigment increases at higher latitudes as would be expected if it enhances thermoregulatory capacity. No gradual latitudinal

pattern was observed, as might be expected if pigmentation was involved in thermoregulation. However, strong variation was observed between populations that were sympatric or allopatric with *C. aequabilis*. This variation was characterised by dark wings through allopatry in the south of the range and then a step change to much lighter wings at the southern border of sympatry. Pigmentation then increased further north into the sympatric zone, finally returning to allopatry levels at the northern range margin. These patterns are qualitatively similar to variation in pigmentation in *C. aequabilis*, meaning that the data are consistent with what would be expected from convergent character displacement. Overall, the results corroborate recent research that has suggested sexual selection as a primary driver behind the evolution of wing pigmentation in this group." (Author)] Address: Hassall, C., School of Biology, Univ. of Leeds, Leeds, UK12.06.2014. E-mail: c.hassall@leeds.ac.uk

14791. Hill, M.J.; Wood, P.J. (2014): The macroinvertebrate biodiversity and conservation value of garden and field ponds along a rural-urban gradient. *Fundamental and Applied Limnology / Archiv für Hydrobiologie* 185: 107-119. (in English) ["The biodiversity and conservation value of semi-natural and field ponds in rural locations are widely acknowledged to be high compared to other freshwater habitats. However, the wider value of urban ponds, and especially garden ponds, has been largely neglected in comparison. This study examines the biodiversity and conservation value of aquatic macroinvertebrates in ponds along an urban-rural continuum over three seasons. Macroinvertebrate faunal richness and diversity of garden ponds (in both urban and sub-urban locations) was markedly lower than that associated with field ponds. The fauna recorded in garden ponds were largely a subset of the taxa recorded in the wider landscape. A total of 146 taxa were recorded from the 26 ponds examined (135 taxa from field ponds and 44 taxa from garden ponds); although only 10 taxa were unique to garden ponds. Garden ponds were frequently managed (macrophytes removed or sediment dredged) and contained artificial fountains or flowing water features which allowed a number of flowing water (lotic) taxa to colonise and persist. Despite the relatively limited faunal diversity and reduced conservation value of garden ponds they have the potential to serve as refugia for some taxa, especially Odonata with highly mobile adults. At the landscape scale, garden ponds provide a diverse and abundant range of freshwater habitats that could play an important role in conserving urban-macroinvertebrate biodiversity. However, for this to be achieved there is a need to provide guidance to home-owners on how this potentially valuable resource can help support freshwater biodiversity." (Authors) Anisoptera: 5 taxa and Zygoptera: 7 taxa; only *Ischnura elegans* is detailed..] Address: Hill, M.J., Centre for Hydrological and Ecosystem Science, Department of Geography, Loughborough University, Loughborough, Leicestershire, LE11 3TU, UK. - 14793.** Hu, Z.; Deng, X.-Y. (2014): Aerodynamic interaction between forewing and hindwing of a hovering dragonfly. *Acta Mechanica Sinica* 30(6): 787-799. (in English) ["The phase change between the forewing and hindwing is a distinct feature that sets dragonfly apart from other insects. In this paper, we investigated the aerodynamic effects of varying forewing-hindwing phase difference with a 60° inclined stroke plane during hovering flight. Force measurements on a pair of mechanical wing models showed that in-phase flight enhanced the forewing lift by 17% and the hindwing lift was reduced at most phase differences. The total lift of both wings was also reduced at most phase differences and only increased at a phase range around in-phase. The results may explain the commonly observed behaviour of the dragonfly where 0° is employed in acceleration. We further investigated the wing-wing interaction mechanism using the digital particle image velocimetry (PIV) system, and found that the forewing generated a downwash flow which is responsible for the lift reduction on the hindwing. On the other hand, an upwash flow resulted from the leading edge vortex of the hindwing helps to enhance lift on the forewing. The results suggest that the dragonflies alter the phase differences to control timing of the occurrence of flow interactions to achieve certain aerodynamic effects." - 14794.** Hupało, K.; Rachalewski, M.; Rachalewska, D.; Tończyk, G. (2014): Gregarine parasitism in two damselfly hosts: Comparison between species, sexes, and sites (Odonata: Calopterygidae). *Odonatologica* 43(3/4): 199-211. (in English) ["We compared gregarine parasitism in imagines of *Calopteryx splendens* (Harris, 1780) and *C. virgo* (Linnaeus, 1758) collected at two sites with sympatric populations in the Spała Landscape Park, Łódź Province, Poland, in July 2012. Gregarine prevalence, intensity, wing load, and aggregation were compared between host species, sexes and sites. Among 140 individuals of both species collected from both sites, 81 (57.8 %) hosted gregarines. The distribution of the parasites was aggregated ($k = 1.0064$) and the highest intensity reached 40 parasites in a single host. There was no difference in gregarine prevalence between species. However, prevalence was different between sexes in both species. Females of *C. splendens* were more often parasitised at site 1, whereas in *C. virgo* males the prevalence was significantly higher at site 2. Secondly, the intensity of parasite infestation and aggregation rate was higher in *C. splendens* at both sampling sites, but we found no differences between sexes except at site 2 where males of *C. splendens* exhibited higher intensity. Thirdly, we found that the parasitism did not affect the damselflies' wing load. Our study revealed differences in patterns of gregarine infection between species, sexes and sampling sites, which confirm that this system of parasitism is complex and influenced by many factors such as physiology and behaviour of the host, environmental conditions or availability of gregarine infectious stages." - 14795.** Ikemeyer, D.; Schneider, T. (2014): *Sympetrum vulgatum decoloratum* und weitere Libellenarten in Quellgebieten des Taurusgebirges (Odonata). *Libellula* 33(3/4): 163-176. (in German, with English summary) ["*Sympetrum vulgatum decoloratum* and other Odonata species in headwaters of the Taurus Mountains – From 17 to 24 August 2013 we visited several dragonfly biotopes in the Taurus Mountains in Turkey, situated in the border zone of the provinces Antalya and Konya between the cities of Gündoğmuş, Tapkent, and Sarıveiler. Most of the habitats were headwater and spring meadows in regions from 1,600 m up to 2,000 m above sea level, but also rivulets and ditches were inspected for dragonflies. *Sympetrum vulgatum decoloratum* (Selys, 1884) was found mainly at headwater regions in good numbers. These habitats were above the treeline and surrounded by bulrushes and/or reed. The depth of the water was mainly less than 50 cm. In total 19 Odonata species were found in this region. The most common co-occurring indigenous species are *Ischnura pumilio*, *Lestes barbarus*, *Orthetrum brunneum*, and *Sympetrum flaveolum*, and further on, less common species are *Sympetrum fonscolombii* and *Sympetrum striolatum*. *Sympetrum haritonovi* Borisov, 1983, was not found. All headwater regions are potentially threatened by road building, water engineering and agricultural use. In worst cases the anthropogenic impacts caused the total loss of habitats for Odonata species." (Authors)] Address: Ikemeyer, D., Billerbecker Str. 6, 48329 Havixbeck, Germany. 14797. Jenkins, D.; Mizell, R.; Vanbloem, S.; Whitmore, S.; Wiscovitch, L.; Zaleski, K.; Goenaga, R. (2014): An analysis of arthropod interceptions by APHIS-PPQ and customs and border patrol in Puerto Rico. *American Entomologist* 60(1): 44-57. (in English) ["Interpretive Summary: We analyzed arthropod interceptions made by regulatory agencies on traffic coming into and leaving Puerto Rico with the intention of finding patterns that may help predict potential invaders and sources of invasions. The majority (77%) of the arthropods intercepted entering Puerto Rico were intercepted in freight or luggage originating within the Caribbean. We found that the insect order Hemiptera (including scales and mealybugs) were the most frequently intercepted group of arthropods. The order Hemiptera also includes many potential agriculture and environmental pests. A survey of 18 exotic arthropods present in both Puerto Rico and Florida found that the vast majority (89%) are reported from Florida prior to being reported in Puerto Rico. This is likely due to the fact that there are no regulatory barriers between the mainland US and Puerto Rico. Finally, we highlight several exotic arthropods that have recently established in Puerto Rico and discuss what we can learn from these invaders. This work analyzes the patterns of arthropod interceptions by regulatory agencies in the Caribbean, discusses past invasions and their impact, and highlights the weaknesses of the current system of pest-detection. This work will be used to inform future monitoring and detection practices. Technical Abstract: USDA Animal Plant Health Inspection Service Plant Protection and Quarantine (APHIS-PPQ) and Customs and Border Patrol (CBP) inspect traffic entering the United States for arthropods that pose a threat to national agriculture and/or ecosystems. We analyzed interceptions made by these agencies in Puerto Rico and the U.S. Virgin Islands between October 2006 and December 2009 for patterns with regard to the frequency of interceptions, origins of interceptions, and the taxa intercepted. 6952 arthropods were intercepted in freight or luggage entering Puerto Rico and the U.S. Virgin Islands from foreign countries and 9840 arthropods were intercepted from freight or luggage leaving Puerto Rico or the U.S. Virgin Islands destined for mainland U.S. The majority (77%) of the arthropods intercepted entering Puerto Rico were intercepted in freight or luggage originating within the Caribbean. The majority of intercepted arthropods were in the

order Hemiptera (52% of all interceptions), followed by Diptera (16%), Coleoptera (10%), Lepidoptera (8%), Thysanoptera (5%), Acari (4%), and Hymenoptera (2%). The remaining orders (Psocoptera, Collembola, Thysanoptera, Orthoptera, Neuroptera, Isoptera, and Odonata) each comprised less than 1%. The proportions of arthropod orders intercepted from foreign countries were different from the proportions of orders intercepted from Puerto Rico and the US Virgin Islands. Intercepted arthropods from foreign countries were more equitably spread among orders, whereas 89% of the arthropods intercepted from Puerto Rico and the US Virgin Islands were in the orders Hemiptera and Diptera. Hemiptera made up the majority of interceptions in traffic entering Puerto Rico and leaving Puerto Rico. However, the Hemiptera made up 28% of the interceptions from foreign countries, but 69% of the interceptions made from Puerto Rico and the US Virgin Islands. Only 7 of 28 exotic arthropods recently established in Puerto Rico were intercepted during this study and these were intercepted at relatively low frequency (between 3 and 132 interceptions; mean of 35 interceptions). We present data suggesting that most exotic arthropods that occur in both Puerto Rico and Florida established in Florida first, likely due to less stringent or non-existent import inspections for traffic coming into Puerto Rico from the U.S. Finally, we highlight several exotic arthropods that have recently established in Puerto Rico and discuss what we can learn from these invaders." 14798. Jo, H.; Gim, J.-A.; Jeong, K.-S.; Kim, H.-S.; Joo, G.-J. (2014): Application of DNA barcoding for identification of freshwater carnivorous fish diets: Is number of prey items dependent on size class for *Micropterus salmoides*?. *Ecology and Evolution* 4(2): 219-229. (in English) ["Understanding predator-prey interactions is a major challenge in ecological studies. In particular, the accurate identification of prey is a fundamental requirement in elucidating food-web structure. This study took a molecular approach in determining the species identity of consumed prey items of a freshwater carnivorous fish (largemouth bass, *Micropterus salmoides*), according to their size class. Thirty randomly selected gut samples were categorized into three size classes, based on the total length of the bass. Using the universal primer for the mtDNA cytochrome oxidase I (COI) region, polymerase chain reaction (PCR) amplification was performed on unidentified gut contents and then sequenced after cloning. Two gut samples were completely empty, and DNA materials from 27 of 28 gut samples were successfully amplified by PCR (success rate: 96.4%). Sequence database navigation yielded a total of 308 clones, containing DNA from 26 prey items. They comprised four phyla, including seven classes, 12 orders, and 12 families based on BLAST and BOLD database searches. The results indicate that largemouth bass show selective preferences in prey item consumption as they mature. These results

corroborate a hypothesis, presence of ontogenetic diet shift, derived through other methodological approaches. Despite the practical limitations inherent in DNA barcoding analysis, high-resolution (i.e., species level) identification was possible, and the predation patterns of predators of different sizes were identifiable. The utilization of this method is strongly recommended for determining specific predator–prey relationships in complex freshwater ecosystems." 14803. Kok, J.M.; Chahl, J.S. (2014): Systems-level analysis of resonant mechanisms for flapping-wing flyers. *Journal of Aircraft* 51(6): 1833-1841. (in English) ["This paper explores the energetics, efficiency, and performance of flapping-wing actuation. The system-level consequences of energy-saving resonant mechanisms across the full flight envelope of hover, maneuver, and glide of flapping-wing systems is analyzed. A review of the extent to which resonant mechanisms are employed in a dragonfly and how useful they are to a maneuvering flapping-wing micro air vehicle system shows that the value of resonance is limited. It is shown that employing resonant elastic mechanisms in real-world configurations on an aerodynamically efficient flyer could produce insignificant energy savings. This number is further reduced by at least 14% across the operational flapping frequency band of a dragonfly, suggesting that resonance is not the major driver for aerodynamically efficient flyers such as the dragonfly. Using a simple harmonic oscillator as a simplified model, a significant reduction of approximately two to three times in maneuvering limits is demonstrated for a system employing elastic elements. In systems with elastic storage, aeroelastic instabilities leading to reductions in maximum glide speed are possible, especially for aerodynamically dominated systems. It is concluded that the system-level cost of implementing resonant mechanisms indicates against resonance in hover being a primary factor in the design of a dragonfly or dragonfly-inspired aircraft." (2014): Insect predators of mosquitoes of rice fields: portrayal of indirect interactions with alternative prey. *Journal of Entomology and Zoology Studies* 2(5): 97-103. (in English) ["The present commentary highlights the likelihood of indirect interactions in rice fields and allied wetlands using the water bugs, odonate larvae and dytiscid beetles as insect predators of mosquito. The biomass and linkage density of the species were used as input to construct the network and estimate the opportunity of intraguild predation (IGP) and apparent competition (AC). It was evident that IGP increased as a function of insect predator body weight ($r = + 0.907$; $P < 0.05$), while an increase in prey biomass decreased its involvement in AC ($r = - 0.864$; $P < 0.05$). The interaction between mosquito prey and the predators appears to be affected by the biomass and composition of the species assemblage. Assuming chances of IGP and AC, positive preference for mosquito by the insect predators seems to be an important criterion for effective biological control." 14806. Kyerematen, R.; Owusu, E.H.; Acquah-Lampsey, D.; Anderson, R.S.; Ntiamao-Baidu, Y. (2014): Species composition and diversity of insects of the Kogyae Strict Nature Reserve in Ghana. *Open Journal of Ecology* 4: 1061-1079. (in English) ["Kogyae Strict Nature Reserve, the only one in Ghana, was established to promote scientific research, particularly on how nature revitalizes itself after major disasters, and also to check the southward drift of the savannah grassland. This study presents the first comprehensive inventory of species composition and diversity of insects of the Reserve. Insects were surveyed between September 2011 and June 2012 to capture the end of the rainy season, the dry season and the peak of the wet season. Samples were taken from two sites within the Reserve, Dagomba and Oku using various sampling techniques including pitfall traps, malaise traps and sweep nets. Insect communities were characterized in terms of, 1) species richness estimators, 2) species richness, 3) Shannon-Weiner Index of Diversity, 4) Pielou's evenness and 5) Bray-Curtis similarity. A total of 8147 individuals representing 135 families from 21 orders were recorded. This included 107 species of butterflies from 9 families and 20 species of dragonflies from 3 families. Oku recorded the highest species numbers ($S = 63$) and richness ($d = 12.16$) with a high evenness of species ($J = 0.9377$) during the peak of the wet season; and the lowest species numbers ($S = 58$) and Margalef's index of ($d = 10.14$) in January. The highest Shannon diversity index of ($H = 3.927$) was recorded at

Dagomba in January. ... A total of 268 odonates belonging to three families and 20 species were recorded from KSNR, comprising of 16 species from the family Libellulidae, three species from the family Coenagrionidae and one species from the family Calopterygidae. 198 individuals belonging to 17 species were recorded at Dagomba whilst 70 species belonging to 11 species were recorded at Oku. Dagomba (ED2) recorded the highest abundance ($N = 82$) as well as species numbers ($S = 14$) of dragonflies during the January sampling corroborated by the highest Shannon Weiner H' of 2.41, while the lowest species numbers ($S = 6$) and richness ($d = 1.6$) were recorded at Oku (EO3) during the June sampling. Dagomba (ED1) had a relatively low evenness during the September sampling (Table 3)." (Authors) The samples of Odonata are not identified at species level.] Address: Kyerematen, Rosina, Department of Animal Biology and Conservation Science, Univ. of Ghana, Legon, Ghana. 14807. Laaß, M.; Hoff, C. (2014): The earliest evidence of damselfly-like endophytic oviposition in the fossil record. *Lethaia* 48(1): 115-124. (in English) ["The reproductive strategy of insects of inserting eggs into plant tissue (endophytic oviposition) is known from the Late Carboniferous onwards. The earliest known ovipositional scars are large, that is up to 38 mm long, and irregular both in size and in shape, and they are not arranged in a regular pattern. Oviposition patterns resembling those of present-day Odonata are first reported from the Late Palaeozoic. These egg cavities are generally of smaller size and have a regular oval shape. They are usually arranged in longitudinal rows or in a zigzag configuration. The most likely tracemakers were gracile damselfly-like insects such as the Archizygoptera, a group closely related to modern Zygoptera. In this paper, the earliest evidence of endophytic oviposition resembling the 'Coenagrionid Type' of Odonatoptera is described. It derives from the Wettin member of the Siebigerode Formation of the Saale-Basin in Central Germany (Upper Carboniferous, Gzhelian) and consists of about 49 elliptical scars with lengths of about 2 mm, probably deposited on a leaf of *Cordaites*. The arrangement of the scars in short transverse rows, their regular size and elliptical shape suggest that the tracemaker was probably a member of the extinct odonatopteran suborder Archizygoptera. If so, the tracefossil described here would be the earliest evidence for this endophytic oviposition in an ancestral group of modern Zygoptera." 14808. Lima, S.L.; Blackwell, B.F.; DeVault, T.L.; Fernández-Juricic, E. (2014): Animal reactions to oncoming vehicles: a conceptual review. *Biological Reviews* 90(1): 60-76. (in English) ["Animal-vehicle collisions (AVCs) are a substantial problem in a human-dominated world, but little is

known about what goes wrong, from the animal's perspective, when a collision occurs with an automobile, boat, or aircraft. Our goal is to provide insight into reactions of animals to oncoming vehicles when collisions might be imminent. Avoiding a collision requires successful vehicle detection, threat assessment, and evasive behaviour; failures can occur at any of these stages. Vehicle detection seems fairly straightforward in many cases, but depends critically on the sensory capabilities of a given species. Sensory mechanisms for detection of collisions (looming detectors) may be overwhelmed by vehicle speed. Distractions are a likely problem in vehicle detection, but have not been clearly demonstrated in any system beyond human pedestrians. Many animals likely perceive moving vehicles as non-threatening, and may generally be habituated to their presence. Slow or minimal threat assessment is thus a likely failure point in many AVCs, but this is not uniformly evident. Animals generally initiate evasive behaviour when a collision appears imminent, usually employing some aspect of native antipredator behaviour. Across taxa, animals exhibit a variety of behaviours when confronted with oncoming vehicles. Among marine mammals, right whales *Eubalaena* spp., manatees *Trichechus* spp., and dugongs *Dugong dugon* are fairly unresponsive to approaching vehicles, suggesting a problem in threat assessment. Others, such as dolphins *Delphinidae*, assess vehicle approach at distance. Little work has been conducted on the behavioural aspects of AVCs involving large mammals and automobiles, despite their prevalence. Available observations suggest that birds do not usually treat flying aircraft as a major threat, often allowing close approach before taking evasive action, as they might in response to natural predators. Inappropriate antipredator behaviour (often involving immobility) is a major source of AVCs in amphibians and terrestrial reptiles. Much behavioural work on AVCs remains to be done across a wide variety of taxa. Such work should provide broad phylogenetic generalizations regarding AVCs and insights into managing AVCs. Soluk, Zercher & Worthington (2011) suggest that the relatively low population size and long adult lifespan of dragonflies (Odonata, Anisoptera) makes them one of the few nonvertebrate groups likely to be impacted by direct AVC mortality. Further, species flight behaviour near roads is a critical metric of potential mortality. At high traffic-volume sites, near wetlands in Illinois USA dragonfly mortality was high although fewer animals attempted to cross (Soluk et al., 2011). Most importantly, the significance of AVC mortality to dragonflies is more pronounced when considering that 63% of species found in the United States are species of conservation concern and, worldwide, 15% of Odonata species are threatened with extinction (Soluk et al., 2011)." 14809. Lojewski, J. (2014): The role of landmarks in territory maintenance by the Black Saddlebags dragonfly,

Tramea lacerata. M.Sc. theses, Graduate School, Eastern Illinois University, Charleston, Illinois: 73 pp. (in English) ["Territoriality can reduce competition for resources, but territorial defense can be costly. Therefore any behaviour that reduces territorial costs may increase the net benefit of territoriality. Some species will align their territory boundaries with conspicuous landmarks that may serve to reduce defense costs. Dragonflies, including *T. lacerata*, defend territories at breeding sites, keeping rival males away to allow themselves access to females. We used three treatments to investigate whether *T. lacerata* used landmarks: constraining landmarks (an object that provided a physical barrier to flight), non-constraining landmarks (an object of the same dimensions and construction that did not impede flight), and a control without landmarks. We observed patrolling male black saddlebags and recorded the locations of turns at their territory boundary and interactions with other dragonflies. When either type of landmark was present, individuals placed their boundary at the landmark far more often than any other location. In addition, individuals that used landmarks had a significantly narrower range of turn locations than those that did not. Unlike other studies the use of a landmark did not seem to reduce defense costs, and interestingly not all individuals used landmarks when they were provided. The lack of an observed reduction in defensive costs could be due to the collection of data during territory maintenance rather than territory establishment, when the costs may have been higher, or landmarks may be important as part of a spatial reference system that aids male dragonflies in efficiently searching for females." (Author)] Address: Lojewski, J., Department of Biological Sciences, Eastern Illinois University, Charleston, IL, 61920, USA

14810. Lucas, G.R.; Michell, P.; Williams, N. (2014): Low cost quarry management producing high gain biodiversity: Using GIS to quantify effective quarry management regimes. In: Hunger, E., Brown, T. J. and Lucas, G. (Eds.): Proceedings of the 17th Extractive Industry Geology Conference, EIG Conferences Ltd. 202 pp: 135-146. (in English) ["A large scale biodiversity study of Cefn Mawr quarry, Mold, North Wales provided a scientific database for the operator. The project aimed to develop a set of 'biodiversity indicators' that would inform sustainable mineral operations at mineral extraction sites whilst simultaneously protecting ecological and landscape interests. The results helped fashion the production of the corporate guideline 'Promotion of biodiversity at the mineral extraction sites of HeidelbergCement'. Cefn Mawr quarry is a Carboniferous limestone quarry providing feedstock for the nearby Padeswood Hanson Cement plant. At the time of the survey it was operated by Castle Cement. A range of ecological surveys were carried out over a six month period (covering late spring, summer and early autumn 2008). They included a JNCC Phase 1 Habitat survey, butterfly and dragonfly surveys and an assessment of water bodies for amphibians. Any habitats not categorised by the JNCC Phase 1 Habitat survey

were described as 'Partial Living Spaces' and were incorporated within the GIS model and used to assess the biodiversity of the site. They added significantly to the biodiversity count and biodiversity indicators. The authors argue that Partial Living Spaces should become part of biodiversity audits at mineral extraction sites because of their contribution to the quantification of biodiversity. Data recorded were analysed within ESRI ArcGIS. The analysis considered the range of habitats and levels of floral diversity found within different zones (operational, restoration and buffer) of the quarry. Wildlife was found to be thriving in the most disturbed parts of the quarry with evidence of a range of species found in the operational zone. Around 300 species of flora were identified on the site. The density of flora (species per hectare) found in the operational and restoration zones of the quarry, together were greater than that in the buffer zone. The buffer zone was considered to be an analogue for the surrounding upland countryside. Statutorily-protected and 'Nationally Scarce' species were also present. The analysis demonstrated that a continuous cycle of disturbance is a key factor in increasing the levels of biodiversity within the quarry. The GIS proved to be an effective tool in recording and analysing the variety of habitats and their species. The quarry had not employed any sophisticated or costly procedures to foster biodiversity. Restoration had been conducted using low cost in-house techniques that had been designed to be cost effective and promote biodiversity. The GIS demonstrated that these techniques had been successful. A number of management approaches were suggested to enhance the biodiversity and are now employed by the quarry as part of the Quarry Biodiversity Management Plan." (Authors) Dragonflies were studied, but no results are presented.] Address: Lucas, G.R., Edge Hill University, Department of Geography and Geology, St Helens Road, Ormskirk, Lancashire L39 4QP, UK. 14811. Mapi-ot, E.P.; Enguito, M.R.C. (2014): Species richness of adult Odonata in Labo River, Ozamiz City. *Journal of Multidisciplinary Studies* 3(1): 86-99. (in English) [Mindanao, Philippines; "Labo River is one of the water systems in Ozamiz City that provides the water needs of the population. Human-related modifications of this water channel have altered the water quality that supports life forms. Invertebrates are important indicators of ecosystem health. Odonata are well-known invertebrates and are of great ecological importance. Fieldwork was conducted from October 2013 to February 2014 in three sampling sites to determine the species richness of Odonata in Labo River, Ozamiz City. Opportunistic sampling method with the use of sweep nets was employed. 21 species were collected of which four are endemic. Of the total species, thirteen are anisopterans and eight are zygopterans that were categorized into three families: Libellulidae, Platycnemididae, Protoneuridae and Coenagrionidae. The low species richness and the presence of indicator species of environmental disturbance suggest that the sites sampled

are already disturbed. Additional sampling should be conducted in Labo River to have a complete database of Odonata." 14812. Marina, C.F.; Bond, J.G.; Muñoz, j.; Valle, j.; Novelo-Gutiérrez, R.; Williams, T. (2014): Efficacy and non-target impact of spinosad, Bti and temephos larvicides for control of Anopheles spp. in an endemic malaria region of southern Mexico. *Parasites & Vectors* 2014, 7:55 doi:10.1186/1756-3305-7-55 : (in English) ["Background: The larvicidal efficacy of the naturally derived insecticide spinosad, for control of immature stages of Anopheles albimanus and associated culicids, was compared to that of synthetic and biological larvicides. Effects on non-target insects were also determined. Methods: A field trial was performed in replicated temporary pools during the rainy season, in southern Mexico. Pools were treated with 10 ppm a.i. spinosad (Tracer 480SC), Bti granules applied at 2 kg/ha (VectoBac WDG, ABG-6511), and 100 ml/ha temephos (50 EC), or an untreated control. Numbers of immature mosquitoes, and aquatic insects in pools were monitored for 20 weeks. Results: Samples of immature mosquitoes comprised approximately 10% An. albimanus, 70% Culex spp. (mostly Cx. melanoconion and Cx. coronator) and 20% Uranotaenia lowii. The most effective larvicides were spinosad and temephos that eliminated An. albimanus in 16 out of 20 post-treatment samples, or 9 weeks of continuous control of immature stages, respectively. These larvicides resulted in 15 and 5 weeks of elimination of Culex spp., respectively, or 20 and 4 weeks of continuous elimination of U. lowii, respectively. Bti treatment provided little consistent control. Aquatic insects were recorded comprising 3 orders, 20 families, 40 genera and 44 species. Shannon diversity index values (H') for aquatic insects were highest in the control (0.997) and Bti (0.974) treatments, intermediate in the spinosad treatment (0.638) and lowest in the temephos treatment (0.520). Severely affected non-target insects in the spinosad and temephos treated pools were predatory Coleoptera, Hemiptera and Odonata, which in the case of spinosad was likely due to the high concentration applied. Bti had little effect on aquatic insects. Conclusions: The spinosad treatment retained larvicidal activity for markedly longer than expected. Spinosad is likely to be an effective tool for control of anopheline and other pool-breeding mosquitoes in tropical regions. Non-target effects of spinosad on aquatic insects merit further study, but were likely related to the concentration of the product used. ... The most severely affected insect species in the spinosad-treated pools were the diving beetle Laccophilus fasciatus (Coleoptera: Dytiscidae), the backswimmer Buena margaritacea (Hemiptera: Notonectidae) and nymphs of the dragonfly Anax amazili (Odonata: Aeshnidae)." 14816. McLoughlin, S.; Martin, S.K.; Beattie, R. (2014): The record of Australian Jurassic plant-arthropod interactions. *Gondwana Research* 27(3): 940-959. (in English) ["Highlights: • Australian Jurassic plants reveal damage referable to seven arthropod feeding strategies. • Damage occurs on numerous ferns and gymnosperms but is prominent on pteridosperms. • Australian Jurassic plants reveal modest physical defences against arthropod herbivory. • Orthoptera, Coleoptera, Hemiptera and Odonata are candidates for the majority of plant damage.

Abstract: A survey of Australian Jurassic plant fossil assemblages reveals examples of foliar and wood damage generated by terrestrial arthropods attributed to leaf-margin feeding, surface feeding, lamina hole feeding, galling, piercing-and-sucking, leaf-mining, boring and oviposition. These types of damage are spread across a wide range of fern and gymnosperm taxa, but are particularly well represented on derived gymnosperm clades, such as Pentoxylales and Bennettitales. Several Australian Jurassic plants show morphological adaptations in the form of minute marginal and apical spines on leaves and bracts, and scales on rachises that likely represent physical defences against arthropod herbivory. Only two entomofaunal assemblages are presently known from the Australian Jurassic but these reveal a moderate range of taxa, particularly among the Orthoptera, Coleoptera, Hemiptera and Odonata, all of which are candidates for the dominant feeding traits evidenced by the fossil leaf and axis damage. The survey reveals that plant-arthropod interactions in the Jurassic at middle to high southern latitudes of southeastern Gondwana incorporated a similar diversity of feeding strategies to those represented in coeval communities from other provinces. Further, the range of arthropod damage types is similar between Late Triassic and Jurassic assemblages from Gondwana despite substantial differences in the major plant taxa, implying that terrestrial invertebrate herbivores were able to successfully transfer to alternative plant hosts during the floristic turnovers at the Triassic–Jurassic transition." (in Chinese, with English summary) ["A methodology of fluid-structure bi-directional interaction based on computational fluid dynamics/computational structure dynamics (CFD/CSD) was presented. The donor-receptor relationship between two sets of grid system was identified by alternating digital tree (ADT). The local interpolation methods were used for data exchange between these two sets of grids. Flow with moving boundaries was dealt with by Delaunay graph mapping method. The code for nonlinear structural finite element and information transfer was developed and used to connect with the code of flow solver 3D2MUFS developed in the Micro Air Vehicle Center of Nanjing University of Aeronautics and Astronautics (NUAA). It was applied to the aerodynamic computation of dragonfly flapping flight with flexible wing. Results show that the time-averaged vertical force coefficient of the dragonfly wing increases from 0.31 to 0.53, and the time-averaged thrust coefficient increases from 0.07 to 0.13 by flexible deformation. This confirms that the flexible deformation can improve the aerodynamic performance of flapping wing." (Authors)] Address: Meng, L.-b., College of Aerospace

14820. Noble, A.; Hassall, C. (2014): Poor ecological quality of urban ponds in northern England: causes and consequences. *Urban Ecosystems* 18(2): 649-662. (in English) ["The value of ponds in urban areas historically has been overlooked. While some recent studies have described considerable biodiversity in urban areas, it is unclear as to how far this extends to different urban habitats. The aims of this study were to determine the condition of 21 urban ponds in Bradford (northern England) and to quantify the connectivity of wetlands in the district. The study showed that macroinvertebrate (including Odonata) and plant biodiversity was substantially lower than would be expected based on pristine reference sites. Of the 21 ponds surveyed, 15 were found to be classified as having very poor ecological quality, with 5 being classed as poor and just 1 was classed as moderate. The number of aquatic plant species found in the ponds ranged from 0 to 6 and the number of macroinvertebrate families found ranged from 4 to 13. It was suspected that the aquatic plant diversity was low due to management techniques such as the removal of emergent vegetation. The average distance to a wetland was found to be higher in urban areas (533 m) compared to rural areas (448 m) although this difference was small, which indicates that the low diversity found in urban ponds is likely due to habitat variables." B* 19 February 2014 vol. 369 no. 1636 20130043: 9 pp. (in English) ["Theories based on optimal sampling by the retina have been widely applied to visual ecology at the level of the optics of the eye, supported by visual behaviour. This leads to speculation about the additional processing that must lie in between—in the brain itself. But fewer studies have adopted a quantitative approach to evaluating the detectability of specific features in these neural pathways. We briefly review this approach with a focus on contrast sensitivity of two parallel pathways for motion processing in insects, one used for analysis of wide-field optic flow, the other for detection of small features. We further use a combination of optical modelling of image blur and physiological recording from both photoreceptors and higher-order small target motion detector neurons sensitive to small targets to show that such neurons operate right at the limits imposed by the optics of the eye and the noise level of single photoreceptors. Despite this, and the limitation of only being able to use information from adjacent receptors to detect target motion, they achieve a contrast sensitivity that rivals that of wide-field motion sensitive pathways in either insects or vertebrates—among the highest in absolute terms seen in any animal." 14823. Outomuro, D.; Cordero Rivera, A.; Nava-Bolanos, A., Cordoba-Aguilar, A. (2014): Does allometry of a sexually selected ornamental trait vary with sexual selection intensity? A multi-species test in damselflies. *Ecological Entomology* 39(3): 399-403. (in English) ["Ornaments may show hyperallometry in certain taxa, i.e. large individuals have proportionally larger ornaments than small ones. One hypothesis suggests that higher sexual selection intensity leads to steeper hyperallometric patterns. This study tested whether an ornamental trait subject to both intra- and intersexual selection showed steeper allometric slopes than when subject solely to intrasexual selection. The study employed the sexually se-

lected male wing pigmentation of 14 calopterygid species (*Hetaerina americana*, *H. cruentata*, *H. occisa*, *H. titia*, *H. vulnerata*, *Calopteryx aquabilis*, *C. haemorrhoidalis*, *C. maculata*, *C. splendens*, *C. virgo*, *Mnesarete pudica*, *Neurobasis chinensis*, *Sapho bicolor*) that differ in sexual selection intensity (intrasexual selection versus intra- and intersexual selection). Hyperallometry was not a uniform pattern in the study species. Furthermore, the allometric slopes did not differ between sexual selection intensities. The allometry of ornamental traits is therefore highly variable even among related species. Other selection pressures – probably species-specific and at a local scale – acting on wing pigmentation might explain the diversity of allometric patterns." 14828. Power, A.; Gilbert, F. (2014): Dragonflies and damselflies of the St Katherine Protectorate. *Egyptian Journal of Biology* 16: 95-100. (in English) ["The indigenous Bedouin tribes of South Sinai (Egypt) irrigate small gardens for agricultural purposes and this has been shown to boost the biodiversity of plants, birds and insects, including dragonflies (Odonata). The gardens offer water-related resources normally in short supply in arid regions. There is very little information available on the dragonflies and damselflies of the Sinai. We assess the importance of Bedouin gardens to Odonata by recording them in the gardens and in unmanaged habitat in the St Katherine Protectorate. The gardens are widely utilised by Odonata: ten species were recorded in total, all observed in the gardens at least once." (Authors)] Address: Power, A., School of Life Sciences, Univ. Nottingham, Nottingham NG7 2RD, UK. E-mail: powera2@tcd.ie

14829. Preston, D.L.; Boland, C.E.; Hoverman, J.T.; Johnson, P.T.J. (2014): Natural enemy ecology: comparing the effects of predation risk, infection risk and disease on host behaviour. *Functional Ecology* 28(6): 1472-1481. (in English) ["(1) Growing interest in unifying the field of natural enemy ecology has revealed similarities between predation and parasitism. In parallel with predation, parasite infection – and even the threat of infection – can alter host traits and indirectly affect community interactions. Nonetheless, few studies have considered multiple

mechanisms of natural enemy-induced behavioural alteration in parallel (e.g. effects before and after enemy contact) or the factors that drive variation in behavioural responses. (2) We first evaluated how the threat of infection by a virulent trematode (*Ribeiroia ondatrae*) compared to the well studied risk of predation in triggering inducible defences in amphibian hosts, prior to direct contact with either enemy. We then evaluated five separate factors that influenced the magnitude of parasite-induced behavioural changes after successful transmission. (3) In both the laboratory and an outdoor mesocosm experiment, we found no evidence that tadpoles of two species (*Pseudacris regilla* and *Anaxyrus boreas*) altered their activity levels in response to chemical cues from uninfected host snails, trematode-infected snails, or from conspecifics actively becoming infected. In contrast, tadpoles sharply reduced their activity in response to lethal predation risks posed by caged dragonfly larvae. (4) After infection, however, *Ribeiroia* caused strong decreases in host activity and escape distance that correlated positively with infection intensity and negatively with host size and developmental stage. Five days after infection with a one-time pulse exposure, hosts recovered to near-normal activity levels. Hosts exposed to a chronic daily exposure of equal intensity, however, continued to decrease activity. Unlike *Ribeiroia*, two less virulent trematodes had no detectable effects on host behaviour. (5) Our results highlight key distinctions between predation and parasitism. The contrasting effects prior to enemy contact may stem from the fact that unlike predation, the consequences of macroparasite infection are intensity-dependent and unpredictable. In contrast, the strong changes in host behaviour after infection are more similar to non-consumptive predator effects in terms of their potential influences on host fitness and community interactions." 14831. Rudolf, V.H.W.; Rasmussen, N.L.; Dibble, C.J.; Van Allen, B.G. (2014): Resolving the roles of body size and species identity in driving functional diversity. *Proc. R. Soc. B* 22 April 2014 vol. 281 no. 1781: 21 pp. (in English) ["Efforts to characterize food webs have generated two influential approaches that reduce the complexity of natural communities. The traditional approach groups individuals based on their species identity, while recently developed approaches group individuals based on their body size. While each approach has provided important insights, they have largely been used in parallel in different systems. Consequently, it remains unclear how body size and species identity interact, hampering our ability to develop a more holistic framework that integrates both approaches. We address this conceptual gap by developing a framework which describes how both approaches are related to each other, revealing that both approaches share common but untested assumptions about how variation across size classes or species influences differences in ecological interactions among consumers. Using freshwater mesocosms with dragonfly larvae (*Erythemis simplicicollis*, *Plathemis lydia*, *Pachydiplax longipennis*) as predators, we then experimentally demonstrate that while body size strongly determined how predators affected communities, these size effects were species specific and frequently nonlinear, violating a key assumption underlying both size- and species-based approaches. Consequently, neither purely species- nor size-based approaches were adequate to predict functional differences among predators. Instead, functional differences emerged from the synergistic effects of body size and species identity. This clearly demonstrates the need to integrate size- and species-based approaches to predict functional diversity within communities." (in English) ["By means of slow-motion film analysis we found new female refusal behaviour patterns against male harassment in a variety of Odonata species. Often, females could escape simply by flying faster than males. Due to the morphological preconditions, there were differences in the two suborders. In Anisoptera, several behavioural specialities were analysed: (a) females of *Aeshna cyanea*, which oviposit solitarily and endophytically, clung to the substrate with great force when being pulled away by attacking males. (b) *Anax imperator* females showed a very fast, characteristic bending of the abdomen causing sudden U-turns for escape. (c) Solitary *Libellula quadrimaculata* females flew loops to escape pursuing males or to shake them off. They either used the impact of the crashing male for the turning moment or they generated it themselves by an abrupt change of the wing beat direction. In Zygoptera we in-

vestigated different *Calopteryx* species, which all oviposit alone. Fleeing was most common but wing clapping, not cooperating to build a tandem, tandem separation, fast diving for submerged oviposition and threatening and attacking the male were also documented. Fast water current prevented submerged oviposition by *Calopteryx xanthostoma* and increased refusal behaviour by females." (Authors)] Address: Hilfert-Rüppell D., Zool. Inst. TU Braunschweig, Fasanenstr. 3, D-38092 Braunschweig, Germany. E-mail: d.hilfert@tu-bs.de

The case of *Heliocypha perforata* (Zygoptera: Chlorocyphidae). *International Journal of Odonatology* 17(4): 181-185. (in English) ["In this paper we record a likely instance of ovo-viviparity in a chlorocyphid damselfly from south-western China. If confirmed, this will be the first record of live birthing in the Odonata: indeed in any member of the Palaeoptera. The widespread Asian damselfly *Heliocypha perforata* (Percheron, 1835) is proposed to be, at least facultatively, viviparous. A female was observed and filmed appearing to deposit pro-larvae directly onto the exposed surface of a half-submerged branch in a small stream in Xishuangbanna Autonomous Dai Prefecture, Yunnan, China. The species is known to deposit eggs in bark crevices close to water but no previous case of actual live births is known." (2014): Environmental integrity and damselfly species composition in Amazonian streams at the "arc of deforestation" region, Mato Grosso, Brazil. *Acta Limnologica Brasiliensia* 26(3): 278-287. (in English, with Portuguese summary) ["Aims: Investigated how the loss of environmental integrity affects damselfly species composition in nine sites with different levels of environmental integrity in a Cerrado-Amazon transition region known as "arc of deforestation" in Mato Grosso State Brazil. We also tested the influence of environmental variables on species composition. Methods: We collected in transects of 100 m and used ordination (PCoA) and simple linear regression. Results: Species composition was strongly influenced by the environmental quality of sites, and the best model to explain species composition included variables related to channel morphology. Conclusions: These results are connected to the environmental homogenization and loss of environmental integrity as a result of extensive agricultural practices which alter stream communities of dragonflies in this region." 14837. Schmitz, M. (2014): Besonders frühe Emergenz von *Aeshna subarctica elisabethae* (Odonata: Aeshnidae). *Libellula* 33(1/2): 63-66. (in German, with English summary) ["Early emergence of *Aeshna subarctica elisabethae* (Odonata: Aeshnidae) – The very early emergence of a female *Aeshna subarctica elisabethae* on 23-v-2009 in the Hahnenmoor, Lower Saxony, is described. This record constitutes the earliest ever documented emergence of the species in Europe. It is assumed that the larva had reached an advanced growth stage in the preceding year, but did not manage to leave the water, thus enabling it to emerge very early the following spring, which was extraordinarily warm and sunny." (Authors)] Address: Schmitz, M., Birkenhang 37, 42555 Velbert-Langenberg, Germany. E-mail: mich.schmitz@gmx.de

14838. Schroth, K. (2014): Morphologische Schlupfhilfen bei Libellenlarven (Odonata). *Libellula* 33(1/2): 1-20. (in German, with English summary) ["Morphological emergence assistances in dragonfly larvae – Dragonfly larvae have a cuticular suture that opens during eclosing as well as during emerging. It is located dorsally at the posterior of the thorax and extends from the wing sheaths base over the prothorax up to the forehead and then runs sideways to the eyes. This suture is very stable and the larva requires some force to open it. Therefore, dragonfly larvae in many cases have morphological emergence and ecdysial assistances to control these in tearing the suture at a certain location in order to reduce the effort and to open it like a zipper. Among the various species this opening assistance is differently formed. The morphological emergence assistances seem to be divided into three basic variants: a) Damselflies have a mark right above the wing sheaths base with a notch

(emergence mark), which is a tear-point where the thoracic suture may crack safely with less effort. At this incipient crack the overlying suture, which usually is folded like a zipper, then tears. b) Dragonflies with a short abdomen have a kind of flap (emergence flap) which can break during emergence through the underlying thorax which is folded in the shape of a peak. In all exuviae this emergence flap can be observed because the skin structures are altered there (Schroth 2012a, 2013). c) In aeshnids there is still most need for further study, because they are rarely found in large numbers as mature larvae and examination under the microscope is difficult because of their large size. This study aims to clarify if the shape of emergence marks in Zygoptera is typical for different species and families, and if they can be used for species determination especially in damselfly larvae. Therefore, 15 species of Zygoptera occurring in the district of Nuremberg (Middle Franconia) have been studied and compared." 14842. Stavenga, D.G. (2014): Thin film and multilayer optics cause structural colors of many insects and birds. *Materials Today: Proceedings*. Volume 1, Supplement, 2014: 109-121. (in English) ["Structural effects contribute to the coloration of many animals. Whereas extremely complex structures have evolved, often coloration is due to the most simple structure, namely a thin film. Here we present a number of examples where thin film optics plays a prominent role, namely in insect wings and bird feathers. Most butterfly wing scales have a lower lamina that prominently determines the colour. Damselfly wings (*Hetaerina americana*) with protrusions have reduced thin film reflections. A limited stack of multilayers features also distinct thin film properties, as is shown for feather barbules of the bird of paradise, Lawes' parotia. A simple method to derive the thickness of the wing structures is described." 14843. Sutton, P.G. (2014): Recent developments regarding the entomological fauna of Corfu (Kerkira). *Antenna* 39(1): 3-14. (in English) [Verbatim: In 2009, following the discovery of a new species of dragonfly for the island, *Selysiothemis nigra*, it was reported that Corfu held a total of 40 species (Sutton, 2009a) and the following comparison was made: Corfu has, by far, the richest odonatan fauna of all the Ionian islands. Only *Coenagrion scitulum* is missing from the Corfu list. In comparison, Kefallonia and Lefkada have 20 species of Odonata, and Zakynthos has 14 species. This situation has now changed, and three new species have been added to the Corfu list: *Coenagrion scitulum*, *Erythromma lindenii*, and *Lindenia tetraphylla*. The former two species, *C. scitulum* and *E. lindenii*, were discovered ... during a survey of Corfu for the exuviae of endemic Odonata species in Greece, in May 2012 (Brochard &

van der Ploeg, 2013a). *C. scitulum* was found at two separate locations: one at a reservoir in the extreme south of the island near Kavos, and the other in the vicinity of some small lakes near Poulades in the Rop a Valley. *E. lindenii* was discovered at the same reservoir as *C. scitulum*, near Kavos. The presence of *S. nigra*, which had been found previously in 2007 (Sutton, loc. cit.) was confirmed by the observation of four larvae and a substantial number (163) of exuviae, but no imagines from this emergence were observed. The paper goes on to describe some of the less frequently seen Odonata of Corfu, providing records for *Gomphus schneiderii*, *Onychogomphus forcipatus*, and *Somatochlora meridionalis*. Of particular importance was the record for *Pyrrhosoma elisabethae*, and the authors state that in spite of their best efforts, this species could only be found at a single site two kilometres south-east of Sidari (Brochard & van der Ploeg, 2013b), with "other locations on Corfu formerly known to hold *P. elisabethae* now so heavily polluted by sewage that it seems improbable that they still hold populations of this species." In the same year *P. elisabethae* had been observed at two different localities on the island, one of which was a well-vegetated spring-fed stream near Dassia to the north of Corfu town (Sutton, 2012a) and at a second site near Vatos, where the source of the three imagines observed was assumed to be the Ropa River and its small tributaries. Sadly, a return visit in October 2013, and a subsequent visit in May 2014, found that the Dassia site had also become heavily polluted with all manner of waste materials including motor vehicle oil containers, and the species could not be refound. For this to have happened, so soon after its discovery at this site was gravely disappointing, but reflects the fact that Greece has yet to recover from a financial situation that has led to the pollution of the countryside with rubbish that the local infrastructure cannot apparently afford to collect. If ever there was a species in desperate need of a champion, it is the Greek Red Damselfly, which is in danger of disappearing without trace before those charged with the stewardship of Corfu's natural riches can come up with an effective strategy to save it from extinction. Brochard & van der Ploeg recorded 30 of the 43 species now known to occur on Corfu, but interestingly, did not report the presence of *Somatochlora flavomaculata*. This species was added to the list by Hämäläinen (1983) when it was described as a species new to Greece, and appears to have been recorded on only three occasions with Hämäläinen's record from Perama in 1981, ... Vatos in 1994 (Lopau, 1999), and ... Lake Korission in 1998 (Butler, 1999). In May 2012, I had the good fortune to share an encounter of an emergence of this species with Bosse and Marie Stille, confirming that it is still present in the vicinity of Vatos. The third species new to the island, *L. tetraphylla*, was reported for the first time when five adult males were found at the Kavos reservoir on 28-vi-2014 (Stille et al. 2014). The authors consider the ecological conditions of the reservoir to be sufficiently favourable to suggest that this species may, in

accordance with observations elsewhere in the Mediterranean, be indigenous to the island.] Address: Sutton, P.G., 2 Fir Tree Close, Flitwick, Beds. MK45 1NZ, UK. E-mail: petersutton@freeuk.com

14844. Tarasova, O.G.; Karygina, N.V. (2014): Zoobenthos of the native riverbed of the Volga River in the conditions of the present oil pollution. Bulletin ASTU. Ser. : Fisheries. 2014(3): 71-77. (in Russian, with English summary) ["The species composition, quantitative indicators of the zoobenthos of the native riverbed of the Volga River were determined. The percentage ratio of number and biomass of the main groups of the benthos has been calculated. Malacostracans (class Crustacea) were the dominant group of zoobenthos, insects (class Insecta) were subdominant. The greatest quantitative indicators were conditioned by the active development of crustaceans and molluscs in 2011 and 2013. The analysis of oil products content in the water and bottom sediments of the studied watercourse has been done. The increase of the concentrations of petroleum hydrocarbons by the average annual values occurred simultaneously with the increase in the number of organisms of benthic fauna. The picture of the spatial distribution was characterized by coincidence of the areas with the elevated levels of petroleum hydrocarbons and quantitative characteristics of the benthos (near villages Zamyany, Nikolskoe). To estimate the intensity of the transition of oil products from the water column into the bottom sediments, using the calculated coefficient of the bottom accumulation, revealed its increase in 2012, which led to the reduction of density and biomass of zoobenthos. The presence of petroleum hydrocarbons in water, in conditions of intensive accumulation of these substances in the bottom sediments, does not have impact on the benthos. Pollution of bottom sediment positively correlates with the number of benthic organisms, and this link is weakened in case of difficult transition of toxins into soils. As a result of the statistical analysis, the presence of relations of different force and direction has been identified after the modernization of data between the investigated parameters. As a result of the researches, it is established that the influence of oil pollution of the water environment on the species composition and quantitative characteristics of the zoobenthos in the conditions of weakening the accumulation of oil products in soils can be negative. Petroleum hydrocarbons can contribute to the growth of benthic organisms in conditions of the moderate pollution of the bottom sediments." (Authors) The list of taxa includes *Orthetrum cancellatum*.] Address: Karygina, Natalia, Caspian Research Institute of Fishery; Senior Researcher of the Laboratory of Water Problems and Toxicology, 414056, Astrakhan, Russia. 14846. Thierry, L.; Zawal, A.; Bonte, D.; Stoks, R. (2014): What factors shape female phenotypes of a poleward-moving damselfly at the edge of its range?. *Biological Journal of the Linnean Society* 112: 556-568. (in English) ["Individuals at the expansion front during a climate-driven range expansion are expected to differ phenotypically from those individuals in core populations. Little information is known about the joint, potentially opposing, effects of stressful conditions at the range edge versus evolutionary changes that take place during range expansion in shaping the phenotypes at the range front. We investigated the effect of range expansion on immune function, body condition and flight-related morphology (flight muscle ratio, wing loading, and wing aspect ratio) of field-collected females of the poleward-moving damselfly *Coenagrion scitulum*. Individuals at the expansion front had a lower body condition, which indicated more stressful conditions at the range edge. Despite the counteracting effect of the shorter growth season, the higher flight muscle ratios at the expansion front indicated a strong selection for dispersal ability during range expansion. The current study suggests that models need to incorporate the interplay of stressful conditions and evolutionary processes at the expansion front to arrive at robust predictions of future species distributions under global warming." 14849. Toubal, O.; Boussehaba, A.; Toubal, A.; Samraoui, B. (2014): Biodiversité méditerranéenne et changements globaux : cas du complexe de zones humides de Guerbès-Senhadja (Algérie). *Physio-Géo* 8: 273-295. (in French, with English summary) ["The Guerbès-Senhadja wetland complex is located in north-eastern Algeria, in water-stressed North Africa, one of the most vulnerable regions to climate change (M. HULME et al., 2001). Although identified as one of the hotspots of biodiversity, and granted a formal protection as a Ramsar site, the ecocomplexe has undergone over the last two decades, fast changes in land use that has left many of its natural habitats heavily impacted and degraded, posing a tough challenge to the sustainable use of its natural resources. As climate change will affect the hydrology of wetlands mostly through changes in precipitation and temperature regimes, we attempted first to investigate warming trend and changes in rainfall patterns in the studied area by comparing these two factors over two periods: 1923-1938 and 1987-2007. Our results are in line with some predictive climatic scenarios which expect temperatures to change in North Africa between 0.2 °C and 0.5 °C per decade (M. HULME et al., 2001). Using remote sensing, we drew up a map of land use and vegetation cover across the studied area as a first step to establish the status of the various ecosystems and to use the map as a tool to assess local ecosystems' resilience to change and to mitigate adverse anthropogenic effects. We also identified factors which are fast eroding the ecological integrity of the study area: human encroachment (urban expansion, fragmentation, etc.), sand quarries, overgrazing, hydrological changes, fires and pollution. We noted that while soil erosion is increasing at low to medium altitudes, wind erosion is gradually silting up the area, including dunary marshes and ponds, thus limiting the carrying capacity of habitats and reducing their biodiversity. The draining of marshes is altering their hydrological functions and is inducing the loss of indigenous and hygrophilous plants, replaced by pyrophilous ones. The dam, located upstream of the study area, is also increasing water pollution by reducing the water flow. In order to stem the increasing erosion of local biodiversity and sustain wetlands resilience (K.L. ERWIN, 2009), steps are urgently needed to provide capacity building to local managers, increase connectivity, maintain hydrology, reduce pollution and control invasive species. The phytoecological diagnostic associated to vegetation and

land use maps can be of tremendous help to the management of the area, its conservation and to the sustainable use of its natural resources in the context of global changes." (Authors) *Acisoma panorpoides* is figured.] Address: Samraoui, B., Laboratoire de recherche et de conservation des zones humides, Université de Guelma, GUELMA, ALGÉRIE et Center of Excellence for Research in Biodiversity, King Saud University, Riyadh, Saudi Arabia. 14850. Tschirnhaus, M. von; Borkenstein, A.; Jödicke, r. (2014): *Lestes dryas* (Odonata: Lestidae) und kommensalische Fliegen (Diptera: Chloropidae), mit einer Übersicht über Kleptoparasitismus bei Halmfliegen. *Mercuriale* 14: 1-12. (in German, with English summary) ["A female *Lestes dryas* caught a planthopper and devoured it within ca 9 min. Ca 2 min after initiation of the feeding process the first individuals of *Conioscinella frontella* arrived and partly succeeded in sucking on the planthopper. For the first time we thus report on kleptoparasitic frit flies (Chloropidae) visiting the prey of a member of Odonata. In addition, a planthopper (Auchenorrhyncha) as prey organism of chloropids is reported for the first time as well. The poor knowledge on this apparently old phylogenetic relation „predator-prey-commensalism" is summarized and compared with that of the sister group, namely freeloader flies (Milichiidae). Arthropods with a repellent odor and disgusting taste, if squeezed or preorally digested by predators, are pre-dominantly used by female flies of certain species as a welcome food. It is unknown if this uncommon food promotes egg ripening or an own defense strategy. A rendezvous strategy may play a role as well. Though all recorded predators are robust arthropods, they scarcely struggle against the troublesome kleptoparasites." 14851. Umbers, K.D.L.; Fabricant, S.A.; Gawryszewski, F.M.; Seago, A.E., Herberstein, M.E. (2014): Reversible colour change in arthropoda. *Biological Reviews* 89(4): 820-848. (in English) ["The mechanisms and functions of reversible colour change in arthropods are highly diverse despite, or perhaps due to, the presence of an exoskeleton. Physiological colour changes, which have been recorded in 90 arthropod species, are rapid and are the result of changes in the positioning of microstructures or pigments, or in the refractive index of layers in the integument. By contrast, morphological colour changes, documented in 31 species, involve the anabolism or catabolism of components (e.g. pigments) directly related to the observable colour. In this review we highlight the diversity of mechanisms by which reversible colour change occurs and the evolutionary context and diversity of arthropod taxa in which it has been observed. Further, we discuss the functions of reversible colour change so far proposed, review the limited behavioural and ecological data, and argue that the field requires phylogenetically controlled approaches to understanding the evolution of

reversible colour change. Finally, we encourage biologists to explore new model systems for colour change and to engage scientists from other disciplines; continued cross-disciplinary collaboration is the most promising approach to this nexus of biology, physics, and chemistry." (Authors) References to Odonata are documented in Table 1] Address: kate_umbers@uow.edu.au

14852. Vamosi, J.C.; Armbruster, W.S.; Renner, S.S. (2014): Evolutionary ecology of specialization: insights from phylogenetic analysis. *Proc. R. Soc. B* 281: 20142004. <http://dx.doi.org/10.1098/rspb.2014.2004>: 7 pp. (in English) ["In this Special feature, we assemble studies that illustrate phylogenetic approaches to studying salient questions regarding the effect of specialization on lineage diversification. The studies use an array of techniques involving a wide-ranging collection of biological systems (plants, butterflies, fish and amphibians are all represented). Their results reveal that macroevolutionary examination of specialization provides insight into the patterns of trade-offs in specialized systems; in particular, the genetic mechanisms of trade-offs appear to extend to very different aspects of life history in different groups. In turn, because a species may be a specialist from one perspective and a generalist in others, these trade-offs influence whether we perceive specialization to have effects on the evolutionary success of a lineage when we examine specialization only along a single axis. Finally, how geographical range influences speciation and extinction of specialist lineages remains a question offering much potential for further insight." (Authors) The paper includes a reference to Odonata.] Address: Vamosi, J.C., Dept of Biological Sciences, Univ. Calgary, Calgary, Alberta, Canada T2L 0Z3. E-mail: jvamosi@ucalgary.ca

14853. Vieira Damaceno, I.; Buys, S.C.; Carriço da Silva, C.; Ferreira Martins, R. (2014): Inventory of Odonata (Insecta) along the margins of the river Dois de Setembro, municipality of Ecoporanga, northwest of Espírito Santo State. *A. Bol. Mus. Biol. Mello Leitão* (N. sér.) 33: 25-33. (in Portuguese, with English summary) ["An inventory of Odonata collected at the margins of the river Dois de Setembro (municipality of Ecoporanga, northwest of Espírito Santo State) is provided. The fieldwork was carried out from June 2011 to February 2012, in five sites along the margins of the river, including environments with distinct antropization degrees. The specimens were collected with insect aerial nets. A total of 421 specimens were collected, representing 19 species and 15 morphotypes. The species more frequently found are *Erythrodiplax basalis*; *Erythrodiplax umbrata*; *Hetaerina auripennis*; *Perithemis lais*. The occurrence of the following species is recorded for the first time from the State of Espírito Santo: *Acanthagrion cuyabae*; *Enallagma novaehispaniae*; *Lestes forficula*. A population of the endangered species *Leptagrion capixabae* was found." (2014): Biodiversity patterns of nutrient-rich fish ponds and implications for conservation. *Limnology* 15(3): 213-223. (in English) ["Nutrient-rich water bodies are usually expected to host low species richness at the local scale (water body). Nevertheless, they can support a diverse and sometimes unique biodiversity when diversity is considered at a regional scale. This discrepancy between the two scales is well documented for natural water bodies, but little is known about biodiversity of artificial water bodies, like fish ponds. We hypothesise that nutrient-rich water bodies can collectively host high species richness at the regional scale. Thus, these are important ecosystems for the regional conservation of biodiversity. We investigated 84 fish ponds in the Dombes region, France, with five taxonomic groups: macrophytes, phytoplankton, macroinvertebrates, dragonflies, and amphibians. Species richness patterns were determined for a. (single pond), β . (between ponds), and γ . (regional pond network) levels. For most studied species groups, richness per fish pond and at the regional level proved to be relatively high in comparison with natural ponds in other landscapes. Contribution of α -diversity to regional diversity was highest for dragonflies with 41 %, and lowest for amphibians and macrophytes with 16 and 18 %, respectively. For macroinvertebrate families and phytoplankton genera it was intermediate. Contribution of β -diversity to regional diversity was similar for all species groups with 22–25 %. Furthermore, some ponds hosted a large number of less frequent species and some endangered species, indicating that the

conservation of biodiversity of fish ponds must be established at a regional scale." (Authors)] Address: Wezel, A., Department of Agroecology and Environment, ISARA Lyon, 23 rue Jean Baldassini, 69364, Lyon Cedex 07, France. E-mail: wezel@isara.fr

14860. Yeoman, K. (2014): Effect of dragonfly nymph presence and conspecific larvae density on oviposition response of the invasive Asian Tiger Mosquito (*Aedes albopictus*). MSc. thesis, Faculty of The Graduate School, The University of North Carolina at Greensboro: 63 pp. (in English) ["Oviposition site selection is a critical fitness enhancing decision for container breeding insects. Predators have typically been shown to repel gravid females whereas conspecifics have been shown to be attractive at low-intermediate densities but repellent at high densities resulting in hump-shaped relations. The interaction of these two factors has, unfortunately, rarely been studied. In this study, I addressed this question by testing the effect of dragonfly nymphs as larval predators, conspecifics, and their combination on the oviposition response of *Aedes albopictus* mosquitoes. I expected a negative effect of predators, a hump-shaped effect of conspecifics, and a rightward shift in the peak of the hump in the presence of larval predators. I used three levels (0, 1, 3) of caged Odonata nymphs and a range of predetermined conspecific larvae numbers (0, 10, 50, 100, 300, 500). I used two experimental designs: (1) Six 3-by-6 oviposition traps grids each containing all 18 predator-by-larvae combinations; (2) Three transects containing 12 pairs of oviposition traps with both cups containing a similar number of larvae, but one containing a given level (0, 1, 3) of caged nymphs. In the latter, I also cultured a sample of the water medium to evaluate bacterial concentration. Hump-shaped relations of egg number with conspecifics was observed at the grid design for the one nymph level and for the transect design at nymph level zero. The effect predator level on oviposition response was either non-significant or, unexpectedly positive. Due to increased larval mortality in the predator cups, I could not evaluate the third hypothesis concerning the combined effect of conspecifics and predators. Bacterial concentration was negatively associated with number of eggs laid. The absence or positive effect of dragonfly nymphs on *Ae. albopictus* oviposition response is encouraging in terms of its usage as a biocontrol agent for container breeding mosquitoes which in combination with low-intermediate levels of conspecifics could be attractive to gravid female mosquitoes. Their offspring, in turn, will be decimated by the control agent." (Author)] Address: not stated

14865. Abbott, J.C. (2015): *Dragonflies of Texas: A Field Guide*. The University of Texas Press: 466 pp. (in English) ["Including nearly half of all dragonfly species found in North America, here is the definitive field guide to the dragonflies of Texas, which will be a valuable resource for naturalists throughout the region. Texas hosts 160 species of dragonflies, nearly half of the 327 species known in North America, making the state a particularly good place to observe dragonflies in their natural habitats. *Dragonflies of Texas* is the definitive field guide to these insects. It covers all 160 species with in situ photographs and detailed anatomical images as needed. Each species is given a two-page spread that includes photographs of both sexes and known variations when possible, key features, a distribution map, identification, discussion of similar species, status in Texas, habitat, seasonality, and general comments. Many of the groups

also have comparative plates that show anatomically distinctive characteristics. In addition to the species accounts, John Abbott discusses dragonfly anatomy, life history, conservation, names, and photography. He also provides information on species that may eventually be discovered in Texas, state and global conservation rankings, seasonality of all species in chronological order, and additional resources and publications on the identification of dragonflies. 470 pages, colour photos, distribution maps." 14867. Aulio, K. (2015): Kokemäenjoki River Delta, western Finland – Natural treasury in an exceptionally rapidly changing aquatic environment. *International Letters of Natural Sciences* 32: 36-53. (in English) ["The catchment of the River Kokemäenjoki covers ca. 27 100 square kilometers in western Finland, and the length of the river is ca 120 km. The river discharges into the Bothnian Bay, the northern section of the Baltic Sea. The delta is changing and prograding towards the sea exceptionally rapidly. The pace of the growth of the deltaic formations, as well as the major zones of the macrophytic vegetation is nowadays some 30–40 meters a year. This makes the delta the most rapidly changing aquatic and littoral ecosystem in the Northern Europe. The Kokemäenjoki River delta is often characterized as a biological hotspot, and major sections of the estuary are included in several leading international nature conservation programmes, i.e. The Natura 2000 network of the European Union, the intergovernmental The Ramsar Convention on Wetlands, as well as in the IBA, Important Bird Area programme established by the BirdLife International organization. The diversities of both flora and fauna are very high – at least as regards the northern location of the estuary. ... Of the invertebrates, the species composition of dragonflies (Odonata) is best known. There are 25 species of the 55 dragonfly taxa found in Finland. ... The present paper summarizes the data presented in various reports, mainly in Finnish, and majority of them in hardly

accessible depositories." (Author)] Address: Aulio, K., Lankakatu 3 D 16, FI-20660 Littoinen, Finland. E-mail: kai.aulio@gmail.com

14868. Balk, A.; Cassée, E. (2015): Photographic report of a cannibalistic Great emperor (*Anax imperator*). *Brachytron* 17(1): 40-43. (in Dutch, with English summary) ["On June 11th 2014 the authors observed cannibalism among two adult females of *A. imperator* in the 'Amsterdamse Waterleidingduinen' (the Netherlands). We provide a photographic report of this event. Great Emperor normally preys on flying insects smaller than themselves. Cannibalism is unusual for animals the same size since it involves a risk to the predator. One theory suggests that miscommunication between two conspecifics can lead to cannibalism. This way, the female could have mistaken the other individual for a male with mating intentions. This observation confirms opportunistic feeding habits of the species." 14870. Barnard, A.; Fincke, O.; Shields, M.; Xu, M. (2015): Melanic individuals in color polymorphic *Enallagma* damselflies result from phenotypic, not genetic, variation. *International Journal of Odonatology* 18(1): 3-14. (in English) ["Genetically determined colour polymorphisms have a long history in the study of evolutionary change acting on populations. The Odonata exhibit relatively high levels of sex-specific colour polymorphisms in mature adults. In *Ischnura* and *Coenagrion*, female-specific polymorphisms are known to be controlled by Mendelian genes. Nearly half of *Enallagma* species have polymorphic females, but the inheritance of any has yet to be determined. Our aims here were to determine: (1) the inheritance of the colour polymorphism in *E. hageni*; and (2) inherent reproductive characteristics of blue female andromorphs and green heteromorphs reared under

controlled conditions as teneral. Maternal morphs, which developed normal coloration in field enclosures within a week, did not differ in copulation time or clutch size, and their offspring did not differ in sex ratio or survivorship to emergence. Surprisingly, no laboratory-reared offspring developed normal mature coloration. Rather, the initially pale parts of the thorax and abdomen, that normally would turn either blue or green, became melanised. Black novel phenotypes also developed in adults of *E. civile*, *E. anna*, *E. carunculatum*, and *E. annexum* that as larvae or teneral adults were reared to sexual maturity under greenhouse conditions that differed from the laboratory conditions used to rear *E. hageni*. We hypothesize that the phenotypic plasticity in body coloration documented in *Enallagma* results from the quality of UV radiation experienced as a sexually immature adult, which is known to affect melanization in other insects. These examples in *Enallagma* offer insights into the origin of colour novelty in Odonata." (Authors)] Address: Finke, O.M., Dept Zool., Univ. 14872. Bennett, D.M.; Dudley, T.L.; Cooper, S.D.; Sweet, S.S. (2015): Ecology of the invasive New Zealand mud snail, *Potamopyrgus antipodarum* (Hydrobiidae), in a Mediterranean-climate stream system. *Hydrobiologia* 746: 375-399. (in English) ["*P. antipodarum*, is a widely distributed non-native species of management concern on four continents. In a southern California stream, *P. antipodarum* abundance, which ranged from ca. <10 to nearly 150,000 snails m², was related to discharge and temperature patterns. Laboratory experiments indicated that *P. antipodarum* (1) survivorship decreased from 13 to 27°C, but its growth rate was higher at 13 and 20°C than 27°C; (2) grazing rates were similar to those of native algivores in short-term trials; (3) grazing impact was

greater than that of a native hydrobiid snail in longer-term trials; (4) ingested different diatom sizes than some other grazers; (5) reduced the abundances of medium-sized and large diatoms, and several filamentous cyanobacteria and chlorophytes, while increasing the relative abundances of tough filamentous chlorophytes (e.g., *Cladophora*); (6) impact on other grazing invertebrates was species specific, ranging from competition to facilitation; (7) reduced the survivorship of *Anaxyrus boreas* tadpoles; and (8) was consumed by non-native *Procambarus clarkii* and naiads of *Aeshna* and *Argia*. Ecological effects of introduced *P. antipodarum* are subtle, occurring primarily at transitory high densities, but flow regulation may enhance their effects by eliminating high flows that reduce their population sizes. Large crayfish (*Procambarus clarkii*[10 cm) had the highest predation rates on New Zealand mud snails followed by medium *Procambarus* (5–10 cm), the dragonfly *Aeshna walkeri*, and small *Procambarus* (5 cm) (Fig. 13). The damselfly *Argia vivida* also had predator impact indices significantly different from zero, but other taxa only consumed mud snails sporadically (*Protochauliodes*, *Cordulegaster dorsalis*, *Octogomphus specularis*, *Notonecta hoffmanni*, *Drunella* sp., *Paltothemis lineatipes*) or not at all (*Rhyacophila* sp., *Isoperla* sp., *Lepidostoma* sp. *Gumaga nigricula*." 14874. Booth, A.J.; Moss, S.; Weyl, O.L.F. (2015): Effect of rotenone on gill-respiring and plastron-respiring insects. *African Journal of Aquatic Science* 40(1): 95-100. (in English) ["Rotenone, a commonly-used piscicide, interferes with the cellular respiration of aquatic vertebrates and invertebrates by preventing the uptake of oxygen. While dose-response relationships have been developed for fish, there are limited comparative data available on aquatic insects that respire either with tracheal gills or with a plastron – a thin layer of air trapped by hairs on the exterior of the body. This study assesses the temperature-dependent toxicity of rotenone to gill-respiring aquatic insects, family Coenagrionidae, and plastron-respiring aquatic insects, family Corixidae, at concentrations that are lethal to Mozambique tilapia *Oreochromis mossambicus*. Both groups of insects were found to be differentially susceptible to rotenone, with survival decreasing as functions of both increased concentration and temperature. The dose-response relationship of Mozambique tilapia was found to be similar to that of other fishes, with 100% mortality achieved at 0.025 mg l⁻¹ at both 20°C and 28°C.

At this concentration, mortality in gill-respiring insects after 48h was 10% at 20°C and 28% at 28°C, which was higher than that of plastron-respiring insects, being 2% and 7% at the same temperatures. At higher concentrations (0.05–0.10 mg l⁻¹), however, mortality of both gill. (>50%) and plastron-respiring (>10%) insects became substantial." 14876. Bucciarelli, G.M.; Kats, L.B. (2015): Effects of newt chemical cues on the distribution and foraging behavior of stream macroinvertebrates. *Hydrobiologia* 749: 69-91. (in English) ["Many amphibians possess noxious or toxic substances for self defense. These compounds have been characterized largely as chemical defenses, but may promote ecological and evolutionary processes. The California newt, *Taricha torosa*, possesses a potent neurotoxin, tetrodotoxin (TTX), which serves as a chemical defense, chemical cue to conspecifics, and selection pressure that has selected for evolved resistance in a predator. However, the potential effects of TTX upon the broader community and on behaviour, in general, have been overlooked. Field assays conducted during the newt breeding season indicate that the macroinvertebrate community responds to adult newt chemical cues by altering foraging behaviour. In these assays, significantly fewer macroinvertebrates were found in experimental areas with enclosed newts relative to enclosures with a non-predatory amphibian. Laboratory bioassays showed that dragonfly nymphs (*Anax junius*) reduced predatory behaviour and moved less in the presence of adult newt chemical cues. When exposed to TTX, nymph mean angular velocities were reduced four fold and mean velocity magnitude was reduced threefold relative to controls. Overall, these results support the hypothesis that chemical stimuli from predators, and TTX specifically, can shape species interactions at lower trophic levels and potentially affect community organization." 14878. Buggenum, H.J.M. van; Geraeds, R.P.G. (2015): An ecological analyses of the Middelsgraaf brook (NL), a canalized low land stream, based on the presence of dragonflies. *Brachytron* 17(1): 3-15. (in Dutch, with English summary) ["The presence and distribution of the Odonata along the Middelsgraaf, a small canalized lowland stream in the Dutch province of Limburg, was studied during the period 2008-2012. Based on the occurrence and abundance of dragonflies along 24 transects of 250 meters each (e.g. wide spread, presence of larvae or exuviae or numbers of adults) we determined 20 species as resident and 10 species as nonresident (wanderers/migrants). Recently a method was developed to use the habitat preferences of the macrofauna species for the characterisation of streams, lakes and other water bodies. Since the regional water authority Roer and Overmaas monitored both water quality and macro-fauna of the Middelsgraaf brook, we were able to compare the results of three different approaches. In our situation it turned out that the stocktaking of the adult dragonflies indicates more or less the same habitat characteristics and water quality as the whole macro-fauna community. Furthermore the indications for the water quality are the same as the ones that are actually measured. So monitoring dragonflies is a simple method that can be used, for example, to characterize water bodies and to investigate habitat differences between brooks, local situations and external aspects that have an influence on the occurrence of dragonflies." 14879. Chapman, J.W.; Reynolds, D.R.; Kenneth Wilson, K. (2015): Long-range seasonal migration in insects: mechanisms, evolutionary drivers and ecological

consequences. *Ecology Letters* 18(3): 287-302. (in English) ["Myriad tiny insect species take to the air to engage in windborne migration, but entomology also has its 'charismatic megafauna' of butterflies, large moths, dragonflies and locusts. The spectacular migrations of large day-flying insects have long fascinated humankind, and since the advent of radar entomology much has been revealed about high-altitude night-time insect migrations. Over the last decade, there have been significant advances in insect migration research, which we review here. In particular, we highlight: (1) notable improvements in our understanding of lepidopteran navigation strategies, including the hitherto unsuspected capabilities of high-altitude migrants to select favourable winds and orientate adaptively, (2) progress in unravelling the neuronal mechanisms underlying sun compass orientation and in identifying the genetic complex underpinning key traits associated with migration behaviour and performance in the monarch butterfly, and (3) improvements in our knowledge of the multifaceted interactions between disease agents and insect migrants, in terms of direct effects on migration success and pathogen spread, and indirect effects on the evolution of migratory systems. We conclude by highlighting the progress that can be made through inter-phyla comparisons, and identify future research areas that will enhance our understanding of insect migration strategies within an eco-evolutionary perspective." Aisenberg (eds.): *Cryptic female choice in arthropods. Patterns, mechanisms and prospects*. Springer: 239-253. (in English) ["Odonates have been frequently labeled as a taxa where males control female's mating and fertilization decisions. Contrary to this position, in our contribution, we review instances where females can actually show choice of mates. Previous to mating, possible selected male traits are wing pigmentation, ability to defend oviposition sites, body color, and temperature. Females may assess male stimulation during copulation, responding via sperm ejection of previous males' sperm. Benefits females may derive from choosing males that can affect offspring are as follows: an increased ability to withstand pathogen infections (for both male and female offspring) or ability to stimulate, attractiveness, and fighting ability (for male offspring only). Finally, we discuss that even for traits that clearly seem to control female reproductive decisions, i.e., abdominal claspers, there is no conclusive evidence that shows that they have evolved and are maintained via male-male competition. Our review thus emphasizes that we are far from admitting that females have little or no reproductive control in this taxa." (Authors)] Address:

(2015): Aquatic macroinvertebrate fauna of the Kis-Sárrét nature protection area with first records of five species from Hungary. *Acta Biol. Debr. Oecol. Hung.* 33: 9-70. (in English, with Hungarian summary) ["The Kis-Sárrét is one of the most diversified and most precious protected areas of the Körös-Maros National Park, but so far, our knowledge about its aquatic macroinvertebrate fauna was far from exhaustive, and only 163 species have been known. In this study, our aim was to explore the aquatic macroinvertebrate fauna in detail and to compile the annotated checklist of aquatic macroinvertebrates of the area. Thorough faunistical samplings were made in three consecutive years (2012-2014) in three seasons (spring, summer and autumn) in each year at a total of 151 sampling points. Altogether 33 892 individuals belonging to 441 species (... 30 Odonata, ...) were identified. The relatively high numbers of species were impressive in themselves, but the composition was much more surprising. Nearly a quarter of the species (110 of 441, 24.9%) could be highlighted in various aspects. Five species were found in Hungary for the first time..., nine species are protected or IUCN red listed (... *Aeshna isosceles*, *Libellula fulva*, *Leucorrhinia pectoralis*, ...), further 94 species are rare or extremely rare in Hungary (e.g. ... *Erythromma lindenii*, ...), or their occurrences in a lowland area are surprising The faunal composition is an interesting mixture of typical marshland species, acidophil bog-dwelling elements and characteristic species of unique slow-flowing, densely vegetated lowland streams." 14883. De Marco Júnior, P.; Batista, J.D.; Cabette, H.S. R. (2015): Community assembly of adult odonates in tropical streams: An ecophysiological hypothesis. *PLoS ONE* 10(4): e0123023. doi:10.1371/journal.pone.0123023:

17 pp. (in English) ["Community assembly theory is founded on the premise that the relative importance of local environmental processes and dispersal shapes the compositional structure of metacommunities. The species sorting model predicts that assemblages are dominated by the environmental filtering of species that are readily able to disperse to suitable sites. We propose an ecophysiological hypothesis (EH) for the mechanism underlying the organization of species-sorting odonate metacommunities based on the interplay of thermoregulation, body size and the degree of sunlight availability in small-to-medium tropical streams. Due to thermoregulatory restrictions, the EH predicts (i) that larger species are disfavoured in small streams and (ii) that streams exhibit a nested compositional pattern characterized by species' size distribution. To test the EH, we evaluate the longitudinal distribution of adult Odonata at 19 sites in 1st- to 6th-order streams in the Tropical Cerrado of Brazil. With increasing channel width, the total abundance and species richness of Anisoptera increased, while the abundance of Zygoptera decreased. The first axis of an ordination analysis of the species abundance data was directly related to channel width. Mean and maximum thorax size are positively correlated to channel width, but no relationship was found for the minimum thorax size, suggesting that there is no lower size constraint on the occurrence of these species. Additionally, a nested compositional pattern related to body size was observed. Our results support the EH and its use as an ecological assembly rule based on abiotic factors. Forest cover functions as a filter to determine which species successfully colonize a given site within a metacommunity. As a consequence, the EH also indicates higher threats for small-bodied zygopterans in relation to the loss of riparian forests in tropical streams." (2015): Presence and distribution of mosquito larvae predators and factors influencing their abundance along the Mara River, Kenya and Tanzania. *SpringerPlus* (2015) 4:136: 14 pp. (in English) ["Among all the malaria controlling

measures, biological control of mosquito larvae may be the cheapest and easiest to implement. This study investigated baseline predation of immature mosquitoes by macroinvertebrate predators along the Mara River, determined the diversity of predators and mosquito larvae habitats and the range of their adaptive capacity to water physico-chemical parameters. Between July and August 2011, sampling sites (n=39) along the Mara River were selected and investigated for the presence of macroinvertebrate predators and mosquito larvae. The selected sampling sites were geocoded and each dipped 20 times using standard mosquito larvae dipper to sample mosquito larvae, while a D-frame dip net was used to capture the macroinvertebrate predators. Water physico-chemical parameters (dissolved oxygen, temperature, pH, conductivity, salinity and turbidity) were taken in situ at access points, while hardness and alkalinity were measured titrimetrically. The influence of macroinvertebrate predator occurrence was correlated with mosquito larvae and water quality parameters using Generalized Linear Model (GLM). Predators (n=297) belonging to 3 orders of Hemiptera (54.2%), Odonata (22.9%) and Coleoptera (22.9%), and mosquito larvae (n=4001) belonging to 10 species, which included *An. gambiae* s.l (44.9%), *Culex* spp. (34.8%) and *An. coustani* complex (13.8%), *An. maculipalpis* (3.6%), *An. phaorensis* (1.2%), *An. funestus* group (0.5%), *An. azaniae* (0.4%), *An. hamoni* (0.3%), *An. christyi* (0.3%), *An. ardensis* (0.08%), *An. faini* (0.07%), *An. sergentii* (0.05%) and 0.05% of *Aedes* mosquito larvae which were not identified to species level, due to lack of an appropriate key, were captured from different habitats along the Mara river. It was established that invasion of habitats by the macroinvertebrate predators were partially driven by the presence of mosquito larvae ($p < 0.001$), and the prevailing water physico-chemical parameters (DO, temperature, and turbidity, $p < 0.001$). Understanding abiotic and biotic factors which favour mosquitoes and macroinvertebrate co-occurrence may contribute to the control of malaria." 14887. Drury, J.P.; Grether, G.F. (2015): Interspecific aggression, not interspecific mating, drives character displacement in the wing coloration of male rubyspot damselflies (*Hetaerina*). *Proc. R. Soc. B* 281: 20141737.

<http://dx.doi.org/10.1098/rspb.2014.1737>: 8 pp. (in English) ["Traits that mediate intraspecific social interactions may overlap in closely related sympatric species, resulting in costly between-species interactions. Such interactions have principally interested investigators studying the evolution of reproductive isolation via reproductive character displacement (RCD) or reinforcement, yet in addition to reproductive interference, interspecific trait overlap can lead to costly between-species aggression. Previous research on rubyspot damselflies (*Hetaerina* spp.) demonstrated that sympatric shifts in male wing colour patterns and competitor recognition reduce interspecific aggression, supporting the hypothesis that agonistic character displacement (ACD) drove trait shifts. However, a recent theoretical model shows that RCD overshadows ACD if the same male trait is used for both female mate recognition and male competitor recognition. To determine whether female mate recognition is based on male wing coloration in *Hetaerina*, we conducted a phenotype manipulation experiment. Compared to control males, male *H. americana* with wings manipulated to resemble a sympatric congener (*H. titia*) suffered no reduction in mating success. Thus, female mate recognition is not based on species differences in male wing coloration. Experimental males did, however, experience higher interspecific fighting rates and reduced survival compared to controls. These results greatly strengthen the case for ACD and highlight the mechanistic distinction between ACD and RCD." 14888. Elo, M.; Penttinen, J.; Kotiaho, J.S. (2015): The effect of peatland drainage and restoration on Odonata species richness and abundance. *BMC Ecology* (2015) 15:11: 8 pp. (in English) ["Restoration aims at reversing the trend of habitat degradation, the major threat to biodiversity. In Finland, over the half of the original peatland area has been drained and during recent years restoration of some of the drained peatlands have been accomplished. Short-term effects of the restoration on peatland hydrology, chemistry and vegetation are promising but little is known how other species groups in addition to vascular plants and bryophytes respond to restoration efforts. We studied how abundance and species richness of Odonata respond to restoration by sampling larvae in three sites (restored, drained, pristine) in 12 different study areas. We sampled Odonata larvae before restoration ($n = 12$), during the first ($n = 10$) and the third ($n = 7$) year after restoration and used generalized linear mixed models to analyse the effect of restoration. Before restoration drained sites had lower abundance and species richness than drained sites. During the third year after restoration both abundance and species richness had risen in restored sites. Adults of pre-selected indicator species were detected more often in restored sites than in drained sites. Our results show that Odonatas suffer

from drainage but seem to benefit from peatland restoration and are able to colonize newly formed water pools relatively rapidly." 14890. Farkas, A.; Móra, A. (2015): Contribution to the Odonata fauna of running and standing waters on the flood-plain of the Danube between Ács (1778 rkm) and Dunaföldvár (1560 rkm). *Acta Biol. Debr. Oecol. Hung.* 33: 125-134. (in English, with Hungarian summary) ["In 2013 faunistical studies on odonates were carried out in the Natura 2000 area of the flood-plain of the Danube located in the Danube-Ipoly National Park, with the main subject to detect species of community interest according to the Habitats Directive of the European Union. During our work a total of 26 small watercourses and 13 standing waters were visited usually at one occasion in spring. The study was mainly based on the collections of larvae; in addition, exuviae were also searched for and adults were occasionally recorded. Dragonflies were found at 16 small watercourses and 11 standing waters. A total of 353 larvae and 26 exuviae were collected and 23 specimens were observed as adults, representing altogether 22 species. Our study resulted in many new localities for the majority of the species, since these water bodies received little attention up to date. Five protected species were found (*Aeshna isosceles*, *Coenagrion ornatum*, *Gomphus vulgatissimus*, *Libellula fulva*, *Orthemtrum brunneum*), out of them *C. ornatum* is also a species of community interest. This species was first recorded from two watercourses, among them from Sződrákosi-patak in high numbers. Since the populations of *C. ornatum* is decreasing in Hungary and Europe, those habitats where it occurs in high density, such as the Sződrákosi-patak, are of great conservation value." 14892. Fincke, O.M. (2015): Trade-offs in female signal apparency to males offer alternative anti-harassment strategies for color polymorphic females. *Journal of Evolutionary Biology* 28(4): 931-943. (in English) ["Colour polymorphisms are known to influence receiver behaviour, but how they affect a receiver's ability to detect and recognize individuals in nature is usually unknown. I hypothesized that polymorphic female damselflies represent an evolutionary stable strategy, maintained by trade-offs between the relative apparency of morphs to male receivers. Using field experiments on *Enallagma hageni* and focal studies of *E. hageni* and *E. boreale*, I tested for the first time the predictions that 1) green heteromorphs and blue andromorphs gain differential protection from sexual harassment via background crypsis and sexual mimicry respectively, and 2) female morphs behaviourally optimize their signal apparency to mate-searching males. First, based on male reactions elicited by females, against a high contrast background the two morphs did not differ in being detected by males and once detected, did not differ in being recognized (eliciting sexual reactions). However, on green ferns, heteromorphs were detected less often (elicited only fly-bys) than andromorphs but once detected, the morphs did not differ in being recognized. In contrast, when perched on a dowel with two male signal distractors, andromorphs were detected less often and once detected, were recognized less often than heteromorphs. Second, in fields where females foraged, andromorphs perched higher on vegetation than heteromorphs, and were more often in the vicinity of males. Neither harassment rates nor evasive behaviours differed between morphs. Males aggregated in high density near shore where solitary females were rare. Equilibrium frequencies of these and other colour morphs should reflect the relative ease with which receivers detect and recognize them in the context where they are encountered." 14893. Fu, J.J.; Hefler, Cs.; Qiu, H.H.; Shyy, W. (2015): Effects of aspect ratio on flapping wing aerodynamics in animal flight. *Acta Mechanica Sinica* 30(6): 776-786. (in English) ["Morphology as well as kinematics is a critical determinant of performance in flapping flight. To understand the effects of the structural traits on aerodynamics of bio-flyers, three rectangular wings with aspect ratios $AR = 1, 2$ and 4 performing hovering-like sinusoidal kinematics at wingtip based Reynolds number of 5300 are experimentally investigated. Flow structures on sectional cuts along the wing span are compared. Stronger K-H instability is found on the leading edge vortex of wings with higher aspect ratios. Vortex bursting only appears on the outer spanwise locations of high-aspect-ratio wings. The vortex bursting on high aspect-ratio wings is perhaps one of the reasons why bio-flyers normally have low-aspect-ratio wings. Quantitative analysis exhibits larger dimensionless circulation of the leading edge vortex (LEV) over higher aspect ratio wings except when vortex bursting happens. The average dimensionless circulation of $AR1$ and $AR2$ along the span almost equals the dimensionless circulation at the 50% span. The flow structure and the circulation analysis show that the sinusoidal kinematics suppresses breakdown of the LEV compared with simplified flapping kinematics used in similar studies. The Re effect results on $AR4$ show that in the current Reynolds number range, the overall flow structure is not sensitive to Reynolds number." 14894. Futahashi, R.; Kawahara-Miki, R.; Kinoshita, M.; Yoshitake, K.; Yajima, S.; Arikawa, K.; Fukatsu, T. (2015): Extraordinary diversity of visual opsin genes in dragonflies. *PNAS* 112(11): E1247-E1256. (in English) ["Dragonflies are colourful and large-eyed animals strongly dependent on colour vision. Here we report an extraordinary large number of opsin genes in dragonflies and their characteristic spatiotemporal expression patterns. Exhaustive transcriptomic and genomic surveys of three dragonflies of the family Libellulidae (*Sympetrum frequens*, *Orthetrum albistylum*, and *Libellula fulva*) consistently identified 20 opsin genes, consisting of 4 nonvisual opsin genes and 16 visual opsin genes of 1 UV, 5 short-wavelength (SW), and 10 long-wavelength (LW) type. Comprehensive transcriptomic survey of the other dragonflies representing an additional 10 families also identified as many as 15–33 opsin genes. Molecular phylogenetic analysis revealed dynamic duplications and losses of the opsin genes in the course of evolution. In contrast to many SW and LW genes expressed in adults, only one SW gene and several LW genes were expressed in larvae, reflecting less visual dependence and LW-skewed light conditions for their life-

style under water. In this context, notably, the sand-burrowing or pit-dwelling species tended to lack SW gene expression in larvae. In adult visual organs: (i) many SW genes and a few LW genes were expressed in the dorsal region of compound eyes, presumably for processing SW-skewed light from the sky; (ii) a few SW genes and many LW genes were expressed in the ventral region of compound eyes, probably for perceiving terrestrial objects; and (iii) expression of a specific LW gene was associated with ocelli. Our findings suggest that the stage- and region-specific expressions of the diverse opsin genes underlie the behaviour, ecology, and adaptation of dragonflies." 14897. Gosden, T.P.; Waller, J.T.; Svensson, E.I. (2015): Asymmetric isolating barriers between different microclimatic environments caused by low immigrant survival. *Proceedings of the Royal Society of London B: Biological Sciences* 282 Issue: 1802: 7 pp. (in English) ["Spatially variable selection has the potential to result in local adaptation unless counteracted by gene flow. Therefore, barriers to gene flow will help facilitate divergence between populations that differ in local selection pressures. We performed spatially and temporally replicated reciprocal field transplant experiments between inland and coastal habitats using males of *Enallagma cyathigerum* as our study organism. Males from coastal populations had lower local survival rates than resident males at inland sites, whereas we detected no differences between immigrant and resident males at coastal sites, suggesting asymmetric local adaptation in a source-sink system. There were no intrinsic differences in longevity between males from the different environments suggesting that the observed differences in male survival are environment-dependent and probably caused by local adaptation. Furthermore, the coastal environment was found to be warmer and drier than the inland environment, further suggesting local adaptation to microclimatic factors has led to differential survival of resident and immigrant males. Our results suggest that low survival of immigrant males mediates isolation between closely located populations inhabiting different microclimatic environments." 14898. Guillermo-Ferreira, R.; Gorb, S.N.; Appel, E.; Kovalev, A.; Bispo, P.C. (2015): Variable assessment of wing colouration in aerial contests of the red-winged damselfly *Mnesarete pudica* (Zygoptera, Calopterygidae). *The Science of Nature* (2015) 102:13: 10 pp. (in English) ["Wing pigmentation is a trait that predicts the outcome of male contests in some damselflies. Thus, it is reasonable to suppose that males would have the ability to assess wing pigmentation and adjust investment in a fight according to the costs that the rival may potentially impose. Males of the damselfly *Mnesarete pudica* exhibit red-coloured wings and complex courtship behaviour and engage in striking male-male fights. In this study, we investigated male assessment behaviour during aerial contests. Theory suggests that the relationship between

male resource-holding potential (RHP) and contest duration describes the kind of assessment adopted by males: self-assessment, opponent-only assessment or mutual assessment. A recent theory also suggests that weak and strong males exhibit variations in the assessment strategies adopted. We estimated male RHP through male body size and wing colouration (i.e. pigmentation, wing reflectance spectra and transmission spectra) and studied the relationship between male RHP and contest duration from videodocumented behavioural observations of naturally occurring individual contests in the field. The results showed that males with more opaque wings and larger red spots were more likely to win contests. The relationships between RHP and contest durations partly supported the self-assessment and the mutual assessment models. We then experimentally augmented the pigmented area of the wings, in order to evaluate whether strong and weak males assess rivals' RHP through wing pigmentation. Our experimental manipulation, however, clearly demonstrated that strong males assess rivals' wing pigmentation. We finally suggest that there is a variation in the assessment strategy adopted by males." 14899. Günther, A. (2015): Signalling with clear wings during territorial behaviour and courtship of *Chlorocypha cancellata* (Odonata, Chlorocyphidae). *International Journal of Odonatology* 18(1): 45-54. (in English) ["The reproductive behaviour of the damselfly *Chlorocypha cancellata* (Chlorocyphidae) was filmed at 600 frames per second. Different flight styles including straight, forward flight, threat and courtship display were analysed with respect to changes in wing beat frequency and phase relationships of fore and hind wings. The analysis revealed significant differences in the flight style between non-escalated and escalated threat display as well as changes in the wing beat frequency of a male during courtship dependant on the behaviour of the female. This is the first evidence suggesting that odonate species with clear wings can use specialized flight modes for intraspecific signalling." 14900. Haber, W.A.; Wagner, D.L.; de la Rosa, C. (2015): A new species of *Erythrodiplax* breeding in bromeliads in Costa Rica (Odonata: Libellulidae). *Zootaxa* 3947(3): 386-396. (in English, with Spanish summary) ["We describe a new species, *Erythrodiplax laselva* (Libellulidae), that breeds in bromeliads and *Cochlostema* (Commelinaceae) in the eastern lowlands of Costa Rica. The closest known relative is thought to be *E. castanea*, widespread in Central and South America, and not *E. bromeliicola*, which is known to breed in bromeliads in Cuba and Jamaica. The male, female, genitalia, and

larva are described and illustrated." (Authors)] Address: Haber, W.A., Apdo. 50-5655, Monteverde, Costa Rica. E-mail: bill.haber01@gmail.com

14901. Hadjoudj, S.; Khelifa, R.; Guebailia, A.; Amari, H.; Hadjadj, S.; Zebba, R.; Houhamdie, M.; Moulai, R. (2015): Emergence ecology of *Orthetrum cancellatum*: temporal pattern and microhabitat selection (Odonata: Libellulidae). *Annales de la Société entomologique de France (NS)* 50(3-4): 343-349. (in English, with French summary) ["Knowledge of both phenology and habitat selection are important assets for conservation and management purposes. Generally, aquatic insect species have an optimal season and larval microhabitat in which their survival and reproductive success are high. In odonates, emergence is usually a seasonal-restricted process during which the insect has to find a good timing and a convenient microhabitat to carry out the final ecdysis out of the water. We investigated temporal emergence pattern and microhabitat choice in *Orthetrum cancellatum* in northeast Algeria, which represents the southern limit of its distribution range. The emergence season lasted 56 days starting from 30.IV and ended on 25.VI, showing a peak on 19.V. The time by which 50% of the annual population has emerged (EM50) was 20 days and the sex ratio was slightly male-biased, with 51.53%. Final instar larvae chose areas with relatively dense vegetation, and this selection was positively dependent on the mean vegetation height and not on sex or body size. Height selection was positively dependent only on the support height that the larva chose. We suggest that larvae consider both predation risks and mainly local microclimate to select their emergence site." 14902. Halder, U.; Dey, B. (2015): Biomimetic algorithms for coordinated motion: Theory and implementation. *International Conference on Robotics and Automation (ICRA 2015)* (arXiv:1503.04894v1 [cs.RO]): 18 pp. (in English) ["Drawing inspiration from flight behaviour in biological settings (e.g. territorial battles in dragonflies, and flocking in starlings), this paper demonstrates two strategies for coverage and flocking. Using earlier theoretical studies on mutual motion camouflage, an appropriate steering control law for area coverage has been implemented in a laboratory test-bed equipped with wheeled mobile robots and a Vicon high speed motion capture system. The same test-bed is also used to demonstrate another strategy (based on local information), termed topological velocity alignment, which serves to make agents move in the same direction. The present work illustrates the applicability of biological inspiration in the design of multi-agent robotic collectives." 14904. Harabiš, F.; Dolný, A.; Helebrandová, J.; Rusková, T. (2015): Do egg parasitoids increase the tendency of *Lestes sponsa* (Odonata: Lestidae) to oviposit underwater? Eur. J. Entomol. 112(1): 63-68. (in English) ["The selection of oviposition sites by insects can significantly affect egg mortality. Spreadwing damselflies (Odonata: Lestidae) predominantly lay their eggs in parts of plants growing above the surface of water and only occasionally also those parts growing underwater. Factors affecting the choice of oviposition site and decision to lay underwater are still poorly understood. We examined whether localities with different risk of egg parasitism, different oviposition strategies (above or below the water surface) and the depth at which the eggs were laid, affected the total number of eggs laid, the proportion parasitized and egg mortality. In general, a significantly higher proportion of the eggs laid above the surface of water were parasitized but spreadwing damselflies showed significant preference for laying eggs underwater at both of the sites studied. This preference, however, had a different effect on the overall mortality of eggs at the two sites studied. Hence underwater oviposition by damselflies may be seen as a conditional anti-predator strategy, occurring only if the benefits exceed potential risks. Underwater oviposition may provide additional benefits other than protection against egg parasitism." 14905. Harabiš, F.M.; Dolný, A. (2015): Necessity for the conservation of drainage systems as last refugia for threatened damselfly species, *Coenagrion ornatum*. Insect Conservation and Diversity 8(2): 143-151. (in Eng-

lish) ["(1.) Small streams and rivulets in agricultural landscapes are among the most threatened habitats throughout Europe. Many species occurring primarily within these habitats are listed in the EC Habitats and Species Directive. One example is *C. ornatum*, which was rediscovered during the last decade in the Elbe Valley (Czech Republic) after more than 40 years. The occurrence of this species, however, was observed only at highly altered sites. Several management attempts, unfortunately, had led to the local extinction instead of strengthening of existing populations, precisely because they ignored the habitat preferences of the target species. (2.) This study analysed the effects of several physiochemical and environmental characteristics of 30 ditch segments in relation to the presence and abundance of *C. ornatum*. (3.) The occurrence of *C. ornatum* was found to be positively correlated with the diversity of macrophyte vegetation and negatively with shading. Populations of *C. ornatum* occurred mostly in smaller, well-warmed sections of channel, while the species clearly avoided those sections with gravel or concrete substrates. (4.) The results indicate that under certain circumstances, the ongoing utilisation of channels particularly for drainage accords with the objectives of protecting this species and could substitute for routine conservation management activities. Supplementary effective management should focus on removing overgrowing vegetation, eliminating such negative interventions to the channel as strengthening the stream bed, and encouraging the development of rich vegetation along the watercourses (e.g. by establishing buffers or overflows)." 14907. Hayden, M.T.; Reeves, M.R.; Holyoak, M.; Perdue, M.; King, A.L.; Tobin, S.C. (2015): Thrice as easy to catch! Copper and temperature modulate predator-prey interactions in larval dragonflies and anurans. Ecosphere 6(4):art56. <http://dx.doi.org/10.1890/ES14-00461.1>: 17 pp. ["Amphibians are important indicators of environmental health, and their populations are in worldwide decline. The causes of these declines are diverse and not well understood. In some cases multiple stressors and complex causal mechanisms have been identified. Experimental

studies have shown that contaminants can cause the failure of *Lithobates sylvaticus* tadpoles to initiate predator avoidance behaviours, potentially leading to increased tadpole capture and injury. Copper is a contaminant known to negatively affect amphibians and other aquatic organisms at sub-lethal levels. Mining waste, certain pesticides, vehicle exhaust and brake pad dust are sources of copper, which can enter hydrologic systems through runoff. Additionally, temperature is known to influence predator-prey interactions of ectotherms and is predicted to rise in some areas as climate changes. We examined how copper and temperature affected behaviour and predation dynamics between an odonate predator (*Aeshna sitchensis*) and larval *L. sylvaticus* prey. We found that sublethal concentrations of copper near the analytical detection limits for this element (1.85 µg Cu/L) significantly reduced tadpole and odonate activity. Above-average temperatures (22°C) significantly increased tadpole activity and decreased dragonfly activity, compared with ambient-temperature treatments (17°C). These behavioural responses culminated in an approximately three-fold increase in the number of dragonfly attacks on tadpoles in the elevated-temperature, copper-exposed treatments. We suggest that increased concentrations of dissolved copper and elevated water temperatures are harmful to amphibian prey through maladaptive behavioural responses in the presence of predators." 14908. Hilfert-Rüppell, D. (2015): High frequency and counterstroking: *Calopteryx splendens* female threatening flight. *International Journal of Odonatology* 18(1): 55-64. (in English) ["A hitherto unknown flight pattern of female *Calopteryx splendens* is described. On a day with heavy winds, when no damselfly could fly in open space of the river, I observed and filmed four to six females foraging in a small bay sheltered by bank vegetation. Females fought for perches and showed a threatening flight with counterstroking and high frequency wing-beating. In all other female flight modes the fore and hind wings were beaten nearly in parallel with a much lower beat frequency. As the newly observed flight mode resembles the courting flight mode of males of *C. splendens* the female's threatening flight is compared with it. At landings of both sexes the wings were beaten in a counterstroking mode for one to seven beats, as well. The possible development of female's threatening flight from wing beating during landing of *C. splendens* is discussed. The relevance of these findings is to extend the knowledge about the variety of flight modes in *Calopteryx* females." (Author)] Address: Hilfert-Rüppell D., Zool. Inst. 14909. Hou, D.; Yin, Y.; Zhao, H.; Zhong, Z. (2015): Effects of blood in veins of dragonfly wing on the vibration characteristics. *Computers in Biology and Medicine* 58:

14-19. (in English) ["Highlights: •The microstructures of dragonfly wing are observed by the SEM. •Accurate three-dimensional FE model of the dragonfly forewing is developed. •The blood in veins is considered in the analysis of the mass, moments of inertia and natural frequency/mode. •We report the influence of the blood on the vibration characteristics of the wing for the first time. How the blood in veins of dragonfly wing affects its vibration characteristics is investigated. Based on the experimental results of the wing's morphology and microstructures, including the veins, the membranes and the pterostigma, accurate three-dimensional finite element models of the dragonfly forewing are developed. Considering the blood in veins, the total mass, mass distribution and the moments of inertia of the wing are studied. The natural frequencies/modal shapes are analyzed when the veins are filled with and without blood, respectively. The based natural frequency of the model with blood (189 Hz) is much closer to the experimental result. Relative to bending modal shapes, the torsional ones are affected more significantly by the blood. The results in this article reveal the multi-functions of the blood in dragonfly wings and have important implications for the bionic design of flapping-wing micro air vehicles." 14910. Inomata, N.; Hironaka, K.; Sawada, K.; Kuriwada, T.; Yamahira, K. (2015): Discrepancy in the degree of population differentiation between color-morph frequencies and neutral genetic loci in the damselfly *Ischnura senegalensis* in Okinawa Island, Japan. *Genetica* 143(3): 271-277. (in English) ["Evaluation of relative contribution of natural selection and stochastic processes to population differentiation has been of great interest in evolutionary biology. In a damselfly, *Ischnura senegalensis*, females show colour dimorphism (gynochrome vs. androchrome), and colour-morph frequencies are known to greatly vary among local populations within Okinawa Island, a small island of Ryukyu Archipelago, Japan. In this study, to examine the effects of natural selection and stochastic processes on the within-island variation in colour-morph frequencies, we compared the degree of population differentiation at the colour-morph locus with that at a mitochondrial DNA region and ten nuclear microsatellite loci. F_{ST} values at the neutral loci were close to zero, indicating presence of sufficient gene flow (dispersal of adult individuals) between the local populations. In contrast, F_{ST} values at the colour-morph locus were significantly different from zero. These results suggest that variation in female colour-morph frequencies observed among local populations in Okinawa Island has been caused by divergent selection acting on the phenotype and/or genes tightly linked with the color locus." 14916. Kaur Walia, G.; Kaur, H.; Kaur, J. (2015): Karyomorphological variations in the chromosome complement of *Orthetrum taeniolatum* of family Libellulidae (Odonata: Anisoptera). *Cytologia* 80(1): 95-99. ["*O. taeniolatum*, collected from the Patnitop area of Jammu and Kashmir, has been cytogenetically studied. The species possesses diploid chromosome number $2n=21m$ with X0 type sex determining mechanism. During the course of meiosis, two autosomal bivalents are distinctly large as compared to the remaining autosomal bivalents. The X chromosome also shows the phenomenon of precocious segregation. The reduction in chromosome number from the type number ($2n=25m$) is due to the fusion of two autosomal pairs, which is very common in case of holokinetic chromosomes. This type of karyomorphological variations in the species has been observed for the first time." 14917. Keränen, I. (2015): The extent and causes of interspecific reproductive interactions in damselflies. *Jyväskylä studies in biological and environmental science* 304: 42 pp. (in English) ["As species do not live in isolation from each other, they are faced with an elementary choice when searching for a mating partner: a choice between conand heterospecific individuals. Despite the remarkable research effort on hybridization and its avoidance, there are still some less well covered areas, e.g. what is the role of males in hybridization, what patterns are found in sympatric wild populations, what role do alternative reproductive tactics (ARTs) have on the likelihood of heterospecific matings, and what are the true costs of heterospecific interactions. In this thesis I first quantify

the frequency of hybridization, backcrossing and heterospecific matings in sympatric wild populations of *Calopteryx splendens* and *C. virgo* damselflies in Finland. The possible influence of population densities, relative abundances of the species, and operational sex ratios on the frequency of heterospecific matings is also investigated. The second aim is to investigate how the intensity of territorial competition influences males' reproductive response to a heterospecific female. Finally, I dissect the importance of male ARTs on hybridization propensity and I attempt to quantify the reproductive costs that males' hybridization propensity inflicts among the tactics. The results imply a major role for *C. splendens* males in heterospecific reproductive interactions between the study species. Especially territorial males seem to be prone to hybridization, and the prevalence of hybridization is increased with a high availability of *C. virgo* females. Hybridization seems to be costly because there was high discordance between heterospecific mating frequency and observed numbers of hybrids. However, heterospecific courtship did not reduce conspecific mating success. The results also show that *C. splendens* males are able to adjust their level of heterospecific courtship according to the competitive environment as well as to the ART it follows. My thesis is a step towards understanding the causes of species reproductive interactions in wild populations." 14918. Kietzka, G.J.; Pryke, J.S.; Samways, M.J. (2015): Landscape ecological networks are successful in supporting a diverse dragonfly assemblage. *Insect Conservation and Diversity* 8(3): 229-237. (in English) [(1.) Ecological networks (ENs) are able to mitigate the negative effects of commercial forestry on terrestrial biodiversity, yet this remains untested for the aquatic fauna. Understanding the anthropogenic and natural variables that drive dragonfly diversity at the landscape and habitat scales, allows the design and implementation of ENs that minimise biodiversity loss across production landscapes. (2.) Here, we determine the relative contribution of anthropogenic disturbances and natural environmental variables to dragonfly assemblages within ENs. Sixty sites, of various freshwater body types, were sampled for adult dragonflies across ENs in a commercial forestry landscape. (3.) Overall, species richness was significantly influenced by river width, water turbidity, water depth and the presence of invasive plants. Nevertheless, overall species composition was influenced by water body type, flow rate and substrate type. Further differences were found when analyses were conducted separately for Anisoptera and Zygoptera. (4.) Counter-intuitively, anthropogenic disturbances had less effect on dragonfly species richness and composition than did natural environmental variables, emphasising the importance of conserving natural heterogeneity. Overall, dragonfly diversity can be successfully conserved in ENs

provided that conservation planning incorporates appropriate local scale variables. These results also suggest that impacts on water quality and dragonfly diversity are minimised by well-designed ENs within this production landscape." 14920. Koch, K. (2015): Influence of temperature and photoperiod on embryonic development in the dragonfly *Sympetrum striolatum* (Odonata: Libellulidae). *Physiological Entomology* 40(1): 90-101. (in English) ["Temperature and photoperiod play major roles in insect ecology. Many insect species have fixed degree-days for embryogenesis, with minimum and maximum temperature thresholds for egg and larval development and hatching. Often, photoperiodic changes trigger the transfer into the next life-cycle stadium. However, it is not known whether this distinct pattern also exist in a species with a high level of phenotypic plasticity in life-history traits. In the present study, eggs of *S. striolatum* are reared under different constant and fluctuating temperatures and photoperiodic conditions in several laboratory and field experiments. In general, and as expected, higher temperatures cause faster egg development. However, no general temperature or light-days for eyespot development and hatching are found. The minimum temperature thresholds are distinguished for survival (2°C), embryogenesis (6°C) and larval hatching (above 6°C). Low winter temperatures synchronize hatching. Above 36°C, no eyespots are visible and no larvae hatch. In laboratory experiments, light is neither necessary for eyespot development, nor for hatching. By contrast to the laboratory experiments, the field experiment show that naturally changing temperature and photoperiod play a significant role in the seasonal regulation of embryonic development. The post-eyespot development is more variable and influenced by temperature and photoperiod than the pre-eyespot development. This developmental plasticity at the end of the embryogenesis might be a general

pattern in the Libellulidae, helping them to cope with variation in environmental conditions." (Author)] Address: Koch, Kamilla, Dept of Ecology, Johannes Gutenberg-University Mainz, Becherweg 13, 55128 Mainz, Germany. E-mail: kochka@uni-mainz.de

14921. Koike, M.; Kamoshita, A.; Komatsuda, Y.; Sato, H.; Naganuma, M.; Takatsuto, S. (2015): Development of a new teaching tool aided by ICT for pupils to form a basic concept of insect morphology. *Journal of Science Education in Japan* 39(1): 19-31. (in Japanese, with English summary) ["In this study a new teaching tool aided by ICT was developed for pupils to form a basic concept of insect morphology in elementary school. This tool consists of eighteen panels of heads, thoraxes and abdomens for six kinds of insects (dragonfly, butterfly, fly, honeybee, cicada, mosquito), which are familiar drawings shown in third-grade science textbooks in elementary school. Like a slot machine, three drawings of the head, thorax and abdomen of a given insect must be put together on a PC. This tool was tested for third grade pupils (experimental group) in science class of a public elementary school. Pupils of the same grade (control group) took a conventional lesson in science class. Analyses of answers from questionnaires administered to pupils of both groups showed the following three points: 1) Pupils of the experimental group had much better understanding of the insect morphology when compared with those of the control group. 2) Our teaching tool promoted the learning motivation of the pupils. 3) Pupils of the experimental group pointed out both personal learning and repeated learning as reasons for their better understanding of the learning content in science class. It is thus suggested that our teaching tool is useful for pupils to form a basic concept of insect morphology in elementary school." 14925. Kulkarni, M.R.; Padhye, S.; Vanjare, A.I.; Jakhalekar, S.S.; Shinde, Y.S.; Paripatyadar, S.V.; Sheth, S.D.; Kulkarni, S.; Phuge, S.K.; Bhakare, K. Kulkarni, K.; Pai, K.; Ghate, H.V. (2015): Documenting the fauna of a small temporary pond from Pune, Maharashtra, India. *Journal of Threatened Taxa* 7(6): 7196-7210. (in English) ["Most of the limnological studies in India have focussed on a few taxa of large, permanent water bodies, and pond ecosystems, and related temporary water bodies are neglected. We present here a faunal inventory, with representative photographs, for a single, small temporary pond, reporting over 125 species of strictly aquatic fauna and 25 species of associated fauna, even though we did not identify some groups such as Protozoa, Dip-tera and nymphs of Odonata, etc. The identified species belong to seven taxa of vertebrates and invertebrates together. Arthropoda and Rotifera were the most species rich groups, observed with 83 and 45 representatives, respectively. Coleoptera were the most numerous in terms of species number. Such a small water body holds some endemics as well as otherwise very rare animals and so deserves better attention. We also highlight the potential and importance of such habitats for research and conservation." (Authors). 12 Odonata species are listed.] Address: Ghate, H.V., Dept of Zoology, Modern College, Shivajinagar, Pune, Maharashtra 411005, India. E-mail: hemantghate@gmail.com

14926. Lakew, A.; Moog, O. (2015): A multimetric index based on benthic macroinvertebrates for assessing the ecological status of streams and rivers in central and southeast highlands of Ethiopia. *Hydrobiologia* 751: 229-242. (in English) ["This study presents the development of

a multimetric index using benthic macroinvertebrates (BMI) to assess the ecological health of highland rivers in Ethiopia. BMI were collected from 22 reference and 82 impaired sites determined based on hydro-morphological, land use, and physical and chemical criteria. Of 75 potential metrics tested to integrate the multimetric index, only nine core metrics were selected based on their abilities to distinguish reference and impaired sites, strength of correlation with pertinent environmental parameters, and their independence from other metrics. The metrics retained in the multimetric index were total number of taxa, EPT-BH > 1sp (Ephemeroptera, Plecoptera, and Trichoptera taxa where Baetidae and Hydropsychidae taxa are considered if they consist more than one taxon), % Oligochaeta and Red Chironomidae, % COPTE (Coleoptera, Odonata, Plecoptera, Trichoptera, and Ephemeroptera), % EPT-BCH (EPT without Baetidae, Caenidae, and Hydropsychidae), ASPT-SASS (Average South African Scoring System Per Taxa), FBI (Family Biotic Index), % shredders, and % collector gathering. The final index derived from these metrics was divided into five river quality class (high, good, moderate, poor, and bad). A validation procedure showed that the index is stable along different hydrological conditions and sensitive to the current range of anthropogenic disturbances in Ethiopian highland rivers." 14927. Le Rouzic, A.; Hansen, T.F.; Gosden, T.P.; Svensson, E.I. (2015): Evolutionary time-series analysis reveals the signature of frequency-dependent selection on a female mating polymorphism. *The American Naturalist* 185(6): E182-E196. (in English) ["A major challenge in evolutionary biology is understanding how stochastic and deterministic factors interact and influence macroevolutionary dynamics in natural populations. One classical approach is to record frequency changes of heritable and visible genetic polymorphisms over multiple generations. Here, we combined this approach with a maximum likelihood-based population-genetic model with the aim of understanding and quantifying the evolutionary processes operating on a female mating polymorphism in the blue-tailed damselfly *Ischnura elegans*. Previous studies on this colour polymorphic species have suggested that males form a search image for females, which leads to excessive mating harassment of common female morphs. We analyzed a large temporally and spatially replicated data set of between-generation morph frequency changes in *I. elegans*. Morph frequencies were more stable than expected from genetic drift alone, suggesting the presence of selection toward a stable equilibrium that prevents local loss or fixation of morphs. This can be interpreted as the signature of negative frequency-dependent selection maintaining the phenotypic stasis and genetic diversity in these populations. Our novel analytical approach allows the estimation of the strength of frequency-dependent selection from the morph frequency fluctuations around their

inferred long-term equilibria. This approach can be extended and applied to other polymorphic organisms for which time-series data across multiple generations are available." 14929. Lojewski, J.A.; Switzer, P.V. (2015): The role of landmarks in territory maintenance by the black saddlebags dragonfly, *Tamea lacerata*. *Behavioral Ecology and Sociobiology* 69(3): 347-355. (in English) ["Territoriality can reduce competition for resources, but territorial defense can be costly; therefore, any behaviour that reduces territorial costs may increase the net benefit of territoriality. Some species will align their territory boundaries with conspicuous landmarks that may serve to reduce defense costs. Dragonflies, including *T. lacerata*, defend territories at breeding sites, keeping rival males away to allow themselves access to females. We used three treatments to investigate whether *T. lacerata* used landmarks: constraining landmarks (an object that provided a physical barrier to flight), non-constraining landmarks (an object of the same dimensions and construction that did not impede flight), and a control without landmarks. We observed patrolling male black saddlebags and recorded the locations of turns at their territory boundary and interactions with other dragonflies. When either type of landmark was present, individuals placed their boundary at the landmark far more often than any other location. In addition, individuals that used landmarks had a significantly narrower range of turn locations than those that did not. Unlike other studies, the use of a landmark did not seem to reduce defense costs, and interestingly not all individuals used landmarks when they were provided. We hypothesize that in this species, landmarks may only reduce costs during territory establishment, rather than during territory maintenance. Alternatively, landmarks may serve as part of a spatial reference system that aids male dragonflies in efficiently searching for females, and thus may be more important in increasing benefits rather than decreasing the costs of ter-

itoriality." (Authors)] Address: Switzer, P.V., Dept Biol. Sciences, Eastern Illinois Univ., Charleston, IL, 61920, USA. E-mail: pvswitzer@eiu.edu

14930. Mahdjoub, H.; Khelifa, R.; Zebba, R.; Bouslama, Z.; Houhamdi, M. (2015): Bivoltinism in *Coenagrion mercuriale* (Zygoptera: Odonata) in the southern margin of its distribution range: emergence pattern and larval growth. *African Entomology* 23(1): 59-67. (in English) ["Voltinism is an important life history trait that varies with the environment. In temperate zones, insect populations take a substantially longer time to reach the adult stage in the northern compared to the southern regions. In this study, emergence pattern and larval growth of the threatened *C. mercuriale* were investigated in a population located in the southern limit of its distribution range in order to determine its life history strategies in a hot climate and compare them to those displayed in northern populations. There was no apparent winter diapause. The species produced two generations in a year, with the first generation emerging in mid spring and the second in late summer. The emergence pattern of the first generation was typical of a summer species and lasted 48 days. All larvae emerged by the end of May. Due to some environmental perturbations, the emergence pattern of the second generation was not surveyed, but there was evidence that the emergence season was short (21 days). Larval structure prior to the second emergence of the year showed that only 25% of the population was in the final instar, which explains the shorter emergence season. We assume that the first eggs laid in the spring hatch and grow rapidly to reach the final instar in late summer as a consequence of higher temperatures and potential high food availability. There was a significant seasonal decline in body size in both males and females. The second generation had a significantly smaller body size, presumably due to the short growth season and/or higher growth rate." (Authors)] Address: Khelifa, R., Lab. Ecol. of Terrestrial & Aquatic Systems, Fac. of Sciences, Dept Biol., Badji Mokhtar Univ., Annaba 23000, Algeria. E-mail: rassimkhelifa@gmail.com

(2015): Response of littoral macroinvertebrates to morphological disturbances in Mediterranean lakes: the case of Lake Piediluco (central Italy). *Fundamental and Applied Limnology / Archiv für Hydrobiologie* 186(4): 297-310. (in English) ["The assessment of the impacts of human morphological alterations on lake ecological condition based on littoral benthic fauna is still in its infancy, especially in the Mediterranean area of Europe. Lake Piediluco is a riverine lake, sited in Central Italy, whose water level is strictly regulated for hydroelectric reasons and hence can be classified as a Heavily Modified Water Body (HMWB) according to the E.U. Water Framework Directive (WFD). Here, we aim at comparing the invertebrate assemblages among sites with a different degree of morphological alterations by identifying potential indicator species and metrics sensitive to morphological alterations, and by comparing the fauna composition collected using two sampling procedures (composite vs habitat-specific samples) with different processing times. Our results show that the invertebrate assemblages of Lake Piediluco differed according to the three types of shoreline alteration (natural, soft- and hard-altered sites) and this was more evident when we analyzed the habitat-specific samples. Several taxa, diversity and metrics based on the number of Ephemeroptera, Trichoptera, Odonata and Mollusca taxa (ETO and ETOM) are found to be sensitive to shoreline alterations and are candidates for inclusion in assessment metrics for WFD compliant monitoring of the ecological status of this lake. While habitat-specific sampling provided a more detailed picture of the assemblages, composite samples provided consistent results and could be used when processing cost is an issue." (Authors) Several odonate taxa are used to measure impacts.] Address: Mastrantuono, Luciana, Dept. of Environmental Biology, Sapienza University of Rome. Piazzale Aldo Moro 5. 00185 Roma. Italy. 14934. McCauley, S.; Hammond, J.I.; Frances, D.N.; Mabry, K.E. (2015): Effects of experimental warming on survival, phenology, and morphology of an aquatic insect (Odonata). *Ecological Entomology* 40(3): 211-220. (in English) ["(1.) Organisms can respond to changing climatic conditions in multiple ways including changes in phenology, body size or morphology, and range shifts. Understanding how developmental temperatures affect

insect life-history timing and morphology is crucial because body size and morphology affect multiple aspects of life history, including dispersal ability, whereas phenology can shape population performance and community interactions. (2.) It was experimentally assessed how developmental temperatures experienced by aquatic larvae affected survival, phenology, and adult morphology of dragonflies [*Pachydiplax longipennis* (Burmeister)]. Larvae were reared under three environmental temperatures: ambient, +2.5, and +5°C, corresponding to temperature projections for our study area 50 and 100 years in the future, respectively. Experimental temperature treatments tracked naturally-occurring variation. (3.) Clear effects of temperature were found in the rearing environment on survival and phenology: dragonflies reared at the highest temperatures had the lowest survival rates and emerged from the larval stage approximately 3 weeks earlier than animals reared at ambient temperatures. There was no effect of rearing temperature on overall body size. Although neither the relative wing nor thorax size was affected by warming, a non-significant trend towards an interaction between sex and warming in relative thorax size suggests that males may be more sensitive to warming than females, a pattern that should be investigated further. (4.) Warming strongly affected survival in the larval stage and the phenology of adult emergence. Understanding how warming in the developmental environment affects later life-history stages is critical to interpreting the consequences of warming for organismal performance." 14935. Mendes, T.P.; Cabette, H.S.R.; Juen, L. (2015): Setting boundaries: Environmental and spatial effects on Odonata larvae distribution (Insecta). *Anais da Academia Brasileira de Ciências* 87(1): 239-248. (in English, with Portuguese summary) ["Environmental characteristics and spatial distances between sites have been used to explain species distribution in the environment, through Neutral (space) and Niche theory (environment) predictions. We evaluated the effects of spatial and environmental factors on Odonata larvae distribution along the Suiá-Missú River Basin, state of Mato Grosso. We tested the hypotheses that (1) the environment is the main factor structuring the community due to its ecophysiological requirements; and (2) the pattern, if present, is clearer for Zygoptera. Samples were made in 12 sites on the Suiá-Missú River Basin in three seasons (2007/2008), with a total of 1.382 Odonata larvae, comprising 10 families, 51 genera and 100 morphospecies. The Anisoptera were more abundant than Zygoptera, comprising 81% of all specimens. The environment affected Zygoptera ($R=0.291$; $p=0.007$) and was the main factor structuring the assembly. Thus, Niche theory was confirmed. The absence of this effect on Anisoptera may be due to the ecophysiological adaptations that enable it

to occupy different habitats. Zygoptera larvae are indicators of changes in habitat structure. The effects of environmental variables on larvae ecology emphasize the strong relationship between these organisms and environmental integrity." (Authors)] Address: Mendes, T.P., Programa de Pós-graduação em Ecologia Aquática e Pesca, Instituto de Ciências Biológicas, Universidade Federal do Pará, Rua Augusto Correia, 1, Bairro Guamá, 66075-110 Belém, PA, Brazil

14936. Mihalicz, J.E. (2015): An observation of the overwintering aquatic insects in a Prairie pond in Saskatchewan, Canada. *University of Saskatchewan Undergraduate Research* 1(2): 99-105. (in English) ["In temperate regions freshwater insects annually face the challenge of surviving the winter months or otherwise perishing. Ice formation presents a substantial danger to all life stages, from the eggs to adults. Accordingly, some species have adapted to overwinter within ice and emerge during the spring thaw. The diversity of aquatic species encased in the ice and frozen sediment of a prairie pond in Saskatchewan, Canada and their survival rate upon thawing was assessed in the winter of 2013. A total of 164 specimens were retrieved from the ice and sediment, 73 of which survived after thawing. Survival rate was greatest for *Cymatia americana* (Corixidae, Hemiptera) at 79.6%. Corixids were found in distinct clusters encased in pond ice, a phenomenon not well documented in previous literature. A higher rate of survival was expected among the chironomids, although the value falls within ranges observed in previous studies. Additionally, members of other taxa including Notonectidae (Hemiptera), Haliplidae (Coleoptera), Ceratopogonidae (Diptera), and Coenagrionidae (Odonata) were recovered; however, these specimens exhibited much lower rates of survival. ... All damselfly naiads were found deep within the ice, near the bottom of the sample approximately 24 cm from the surface. These were identified as two possible genera (*Enallagma* and *Coenagrion*) but similarities between them made exact identification difficult." (Author)] Address: Mihalicz, J.E., Department of Biology, College of Arts and Science, University of Saskatchewan, Saskatoon, SK, Canada. E-mail: jem539@mail.usask.ca

14937. Mikolajewski, D.J.; De Block, M.; Stoks, R. (2015): The interplay of adult and larval time constraints shape species differences in larval life history. *Ecology* 96(4): 1128-1138. (in English) ["In animals with a complex life cycle, larval life history plasticity is likely shaped by the interplay of selective factors in both larval and adult stages. A wide interspecific variation in responses to larval time constraints imposed by seasonality has been documented. Few studies have addressed differences among closely related species in the evolutionary trajectories of age and size at metamorphosis and their link with larval growth rate under time constraints. None have considered how species-specific length of the reproductive season affects larval developmental responses to time constraints. We tested *Coenagrion hastulatum*, *C. mercuriale*, *C. ornatum*,

and *C. puella*, whether species with a longer reproductive season, facing a smaller threat of missing out on reproduction, react less to larval time constraints and pre-winter food shortage by accelerating development rate and growth rate, and therefore pay less physiological costs. All species increased development and growth rates under larval time constraints. The magnitude of this increase negatively correlated across species with the length of the reproductive period. Under larval time constraints, only the species exhibiting the longest reproductive season suffered a delayed emergence and a reduced investment in energy storage, yet it also showed an increased immune function. Under a longer reproductive season, evolution may favour compensation for larval constraints after metamorphosis. Growth rate was accelerated after pre-winter food shortage to same extent across species; also effects on age and mass at emergence did not differ among species. Time constraints associated with the length of the reproductive season may predictably contribute to species differences in their response to time constraints imposed in the larval stage. Our study adds empirical proof that the interplay of selective factors in the larval and adult stage may determine life history plasticity with regards to larval time constraints." 14938. Mlynarek, J.J.; Iserbyt, A.; Nagel, L.; Forbes, M.R. (2015): Differential water mite parasitism, phenoloxidase activity, and resistance to mites are unrelated across pairs of related damselfly species. *PLoS ONE* 10(2): e0115539. doi:10.1371/journal.pone.0115539: 13 pp. (in English) ["Related host species often demonstrate differences in prevalence and/or intensity of infection by particular parasite species, as well as different levels of resistance to those parasites. The mechanisms underlying this interspecific variation in parasitism and resistance expression are not well understood. Surprisingly, few researchers have assessed relations between actual levels of parasitism and resistance to parasites seen in nature across multiple host species. The main goal of this study was to determine whether interspecific variation in resistance against ectoparasitic larval water mites either was predictive of interspecific variation in parasitism for ten closely related species of damselflies (grouped into five "species pairs"), or was predicted by interspecific variation in a commonly used measure of innate immunity (total Phenoloxidase or potential PO activity). Two of five species pairs had interspecific differences in proportions of individuals resisting larval *Arrenurus* water mites, only one of five species pairs had species differences in prevalence of larval *Arrenurus* water mites, and another two of five species pairs showed species differences in mean PO activity. Within the two species pairs where species differed in proportion of individuals resisting mites the species with the higher proportion did not have correspondingly higher PO activity levels. Furthermore, the proportion of individuals resisting mites mirrored prevalence of parasitism in only one

species pair. There was no interspecific variation in median intensity of mite infestation within any species pair. We conclude that a species' relative ability to resist particular parasites does not explain interspecific variation in parasitism within species pairs and that neither resistance nor parasitism is reflected by interspecific variation in total PO or potential PO activity." 14940. Mossman, H.L.; Panter, C.J.; Dolman, P.M. (2015): Modelling biodiversity distribution in agricultural landscapes to support ecological network planning. *Landscape and Urban Planning* 141: 59-67. (in English) ["Highlights: • We used ad-hoc biological data to model landscape-scale wetland species richness. • Models were used to assess and improve a proposed ecological connectivity network. • Our evidence-based network was shorter and connected areas of higher richness. • Our results challenge previous assumptions of important network elements. • Odonata were poor proxies for other groups of wetland species. Strategic approaches to biodiversity conservation increasingly emphasise the restoration of ecological connectivity at landscape scales. However, understanding where these connecting elements should be placed in the landscape is critical if they are to provide both value for money and for biodiversity. For such planning to be effective, it is necessary to have information of the distributions of multiple taxa, however, this is of poor quality for many taxa. We show that sparse, non-systematically collected biological records can be modelled using readily available environmental variables to meaningfully predict potential biodiversity richness, including rare and threatened species, across a landscape. Using a large database of ad-hoc biological records (50 501 records of 502 species) we modelled the richness of wetland biodiversity across the Fens, a formerly extensive wetland, now agricultural landscape in

eastern England. We used these models to predict those parts of the agricultural ditch network of greatest potential conservation value and compared this to current strategic network planning. Odonata distribution differed to that of other groups, indicating that single taxon groups may not be effective proxies for other priority biodiversity. Our results challenged previous assumptions that river channels should comprise the main connecting elements in the Fens region. Rather, areas of high ditch density close to a main river are likely to be of greater value and should be targeted for enhancement. This approach can be adopted elsewhere in order to improve the evidence-base for strategic networks plans, increasing their value for money." 14941. Mutlu, O.; Ulak, G.; Kokturk, S.; Celikyurt, I.K.; Akar, F.; Erden, F. (2015): Effects of homeopathic Anax imperator on behavioural and pain models in mice. *Homeopathy* 104(1): 15-23. (in English) ["Background: Homeopathy is a medical theory and practice that asserts that disease can be cured by remedies that produce symptoms in a healthy person similar to those suffered by a patient with a malady. Methods: The aim of this study was to investigate effects of homeopathic Anax imperator (dragonfly) (Anax-i 30c and Anax-i 200c) in the forced swim test (FST), elevated plus-maze (EPM) test, hot plate (HP) test and open field test and examined NPY1 receptor expression, in naive mice. Results: In the FST, treatment with Anax-i 30c or Anax-i 200c significantly diminished immobility time while in EPM test, Anax-i 200c increased the percentage of time spent in open arms as well as the percentage of open arm/total arms. In the HP test, Anax-i 30c or Anax-i 200c decreased the total time mice spent licking their hind paws while in open field test, treatment with Anax-i 200c increased the total distance and speed mice travelled compared to the control group. Three weeks of daily injections with Anax-i 30c or Anax-i 200c caused significant weight loss in mice. Anax-i 30c or Anax-i 200c treatment significantly decreased NPY1 receptor expression, and Anax-i 30c also decreased NPY2 receptor expression. Conclusion: These results suggest that the homeopathic Anax-i exerts antidepressant, anxiolytic and analgesic-like effects and causes hyperlocomotion and weight loss." 14942. Mutonkole Senga, P.; Tshitenge Mbuebue, J.-M.; Masamba, Lulendo, N. (2015): Benthic macroinvertebrates as indicators of water quality: A case-study of urban Funa stream (in Kinshasa, Democratic Republic of Congo). *Open Journal of Water Pollution and Treatment* 2(1): 8-24. (in English) ["Macroinvertebrates ability to indicate various types of anthropogenic stressors is widely

recognized as an integral component of freshwater bio-monitoring. In case of pollution, biodiversity of the aquatic community can be affected and the species composition changes from natural species to tolerant species. In this study, macroinvertebrates were sampled using Surber sampler at 5 locations from October 2007 to September 2008 to determine the environmental quality of Funa water body and to analyze fauna structure assemblages. Water physical chemical data were explored using multivariate analysis of Canonical Component to detect environmental trends. Ten biodiversity indices: specific richness S, abundance A, Shannon-Weiner diversity H', maximum diversity Hmax, evenness J', McNaughton ID, Redundancy R, Capacit'e Biogenique Secondaire (Cb2), Indice Biologique Global Normalis'e (IBGN) and Biologic Monitoring Working Party (BMWP) were used for biological assessment of water quality. Forty-seven species were collected from 3624 specimen dominated by Odonata, Achaeta and Diptera. Four taxa displayed higher relative abundances: Glossiphonidae (20 %), Chironomidae (9 %), Lumbriculidae (9 %) and Hirudidae (8 %). DIMO model splits up sites into two groups in function of H', Hmax, and J'. In addition, rank-frequency diagrams characterized stage 1 and middle between stages 1 and 2 structured curves. In overall, indices showed low values, which expressed the inhospitable character of habitat structure. However, BMWP and IBGN scores of water quality worsened from upstream to downstream." 14944. Naka, H.; Hashimoto, H. (2015): Effects of deformation and vibration characteristics of wings on flapping flight. *Mechanical Engineering Journal* 2(1) paper no. 14-00262: 11 pp. (in English) ["The dragonfly wing is passively deformed under flapping and has the strength to withstand high flapping frequency simultaneously. These characteristics of deformation and vibration of the wing are important for flapping flight. However, the effect of these characteristics on flapping flight has not been well understood. The purpose of this study is to investigate deformation and vibration characteristics of the dragonfly wing, and then to develop an artificial wing suitable for flapping flight on the basis of the dragonfly wing. In this study, natural frequency and deformation of the dragonfly wing are measured, and the artificial wing is fabricated on the basis

of the results. From the measured results, the dragonfly wing has the high natural frequency of about 120 Hz, and thereby, it does not resonate with flapping. Although base-side of the wing is hardly deformed, the tip-side of the wing is greatly deformed because of the torsional deformation from the nodus of dragonfly wing. On the basis of characteristics of the dragonfly wing, the deformable artificial wing that can deform in the same manner of dragonfly wings was fabricated. Then, aerodynamic force and power consumption under flapping when using the deformable artificial wing was measured. As a result, the power efficiency of aerodynamic force using the deformable artificial wing is five times greater than the power efficiency using a non-deformable wing." 14945. Nakamura, K.; Takashima, K. (2015): Geographical variation in diapause development in eggs of *Symptetrum frequens* (Odonata: Libellulidae). *Applied Entomology and Zoology* 50: 263-270. (in English) ["Geographical differences causing variations in the egg period and the effects of environmental factors on diapause development were examined in *S. frequens*, a univoltine species with an obligatory egg diapause for overwintering. Eggs were obtained from females collected from 11 localities in Japan and incubated under six different combinations of photoperiod and temperature. No clear geographical trends were found in the average egg period under any experimental treatment. Average hatch period (i.e., period from the date when 10 % of the eggs were hatched to the date when 90 % of the eggs were hatched) did not display any geographical trend at 25 and 20 °C. However, at 15 °C, a significant negative correlation was observed between the hatch period and the latitude of the collection site. Similarly, a significant correlation was also detected between the coefficient of variation in the egg period and the average annual temperature near the collection site, but only at 15 °C. Because each egg batch was divided into six groups which were then incubated under different experimental conditions, it was possible to discern that the rate of diapause development at 15 °C varies among eggs from southern populations. The large variations in the egg period in the southern populations at 15 °C were considered to be a risk-spreading strategy: a certain proportion of the eggs were able to maintain diapause until winter, even if the adults laid the eggs early in the season. These differences in the rate of diapause development within a population may be an adaptation to the unpredictable length of the summer–autumn period." 14947. Nixon, M.R.; Orr, A.G.; Vukusic, P. (2015): Wrinkles enhance the diffuse reflection from the dragonfly *Rhyothemis resplendens*. *J. R. Soc. Interface* 6 February 2015 vol. 12 no. 103 20140749: 7 pp. (in English) ["The dorsal surfaces of the hindwings of *Rhyothemis resplendens* reflect a deep blue from the multilayer structure in its wing membrane. The layers within this structure are not flat, but distinctly 'wrinkled', with a thickness of several hundred nanometres and interwrinkle crest distances of 5 µm and greater. A comparison between the backscattered light from *R. resplendens* and a similar, but un-'wrinkled' multilayer in *Matronoides cyaneipennis* shows that the angle over which incident light is backscattered is increased by the wrinkling in the *R. resplendens* structure. Whereas the reflection from the flat multilayer of *M. cyaneipennis* is effectively specular, the reflection from the wrinkled *R. resplendens* multilayer spans 1.47 steradians (equivalent to ±40° for all azimuthal angles). This property enhances the visibility of the static wing over a broader angle range than is normally associated with a smooth multilayer, thereby markedly increasing its conspicuousness." 14951. Outomuro, D.; Johansson, F. (2015): Bird predation selects for wing shape and coloration in a damselfly. *Journal of Evolutionary Biology* 28(4): 791-788. (in English) ["Wing shape is related to flight performance, which is expected to be under selection for improving flight behaviours such as predator avoidance. Moreover, wing conspicuousness, usually involved in sexual selection processes, is also relevant in terms of predation risk. In this study, we examined how predation by a passerine bird, the white wagtail *Motacilla alba*, selects wing shape and wing colour patch size in males of *Calopteryx splendens*. The wing colour patch is intra- and intersexually selected in the study species. In a field study, we compared wings of live damselflies to wings of predated damselflies which are always discarded after predation. Based on aerodynamic theory and a previous study on wing shape of territorial tactics in damselflies, we predicted an overall short and broad wing, with a concave front margin shape to be selected by predation. This shape would be expected to improve escaping ability. Moreover, we predicted that wing patch size should be negatively selected by predation. We found that selection operated differently on fore- and

hindwings. In contrast to our predictions, predation favoured a slender general forewing shape. However, the predicted wing shape was favoured in hindwings. We also found selection favouring a narrower wing colour patch. Our results suggest different roles of fore- and hindwings in flight, as previously suggested for *Calopteryx* damselflies and shown for butterflies and moths. Forewings would be more involved in sustained flight and hindwings in flight manoeuvrability. Our results differ somehow from a recently published work in the same study system, but using another population, suggesting that selection can fluctuate across space, despite the simplicity of this predator-prey system." 14955. Richards, S.J.; Theischinger, G. (2015): Chapter 5 Odonata (Dragonflies & Damselflies). In: Richards, S.J. and N. Whitmore (editors) 2015. A rapid biodiversity assessment of Papua New Guinea's Hindenburg Wall region. Wildlife Conservation Society Papua New Guinea Program. Goroka, PNG: 75-83. (in English) ["We report the results of a survey of Odonata at two broad elevations (~285-910 m asl and 1,770-1,850 m asl) on the southern slopes of the Hindenburg Range in western Papua New Guinea (PNG). Fifty-three species were encountered, including 28 species of Zygoptera and 25 species of Anisoptera. Between 13 and 16 of these species (up to 30%) appear to be new to science. Diversity at the lower, foothill sites was much higher (40 species) than at the montane location, which totalled just 14 species despite higher search effort. However the fauna at the montane site was remarkable for the high proportion of species that are new to science (six of 14 species or 43%). Most of the new species documented during this survey are associated with clear, flowing streams in forest. We present the first comprehensive list of odonate species from the upper Ok Tedi area but note that this is based on just 3 weeks of sampling and that the total diversity of this important indicator group is certainly much higher in this topographically diverse part of Papua New Guinea." 14956. Riehl, V. (2015): Morphological characterization of exuvia from co-emerging riverine dragonflies using geometric morphometrics. 14th Annual UW-System Symposium for Undergraduate Research & Creative Activity, 3. Poster Session I, April 24th 2015: 89. (in English) [Verbatim: Among many evolutionary pressures, the physical environment plays a significant role in the refining organism morphology. The purpose of this study is to determine whether geometric morphometrics can be used to differentiate or characterize shape variation among species and sexes of co-emerging riverine dragonflies, including two rare species in New Brunswick, Canada: *Ophiogomphus howei* and *Gomphus ventricosus*. Exuvia from 26 locations along the St. John and Miramichi Rivers were collected in June 2013. Exuvia were identified to species and landmarks were digitized on digital micrographs of the dorsal and ventral surfaces. A multivariate analysis of variance was used to test for differences in body shape between species and sexes within a species. We expect to find significant levels of variation among species in support of taxonomic diagnosis, but fewer differences between sexes with a species. A detailed analysis of shape

will help to confirm the presence of rare and protected species at these sites. Furthermore, this analysis provides a necessary first step toward the examination of phenotypic variation of these species based on differences in habitat hydrology.] Address: Riehl, Valerie, University of Wisconsin-Parkside

14957. Rolfhus, K.R.; Wiener, J.G.; Haro, R.J.; Sandheinrich, M.B.; Bailey, S.W.; Seitz, B.R. (2015): Mercury in streams at Grand Portage National Monument (Minnesota, USA): Assessment of ecosystem sensitivity and ecological risk. *Science of The Total Environment* 514: 192-201. (in English) ["Highlights: •GRPO is an ecosystem that is sensitive to mercury contamination. •MeHg values in GRPO streams and food webs are elevated relative to the region. •Mercury enrichment may be due in part to historic local trading activity. •GRPO fish pose a dietary risk to sensitive piscivores, but not to humans. Abstract: Mercury (Hg) in water, sediment, soils, seston, and biota were quantified for three streams in the Grand Portage National Monument (GRPO) in far northeastern Minnesota to assess ecosystem contamination and the potential for harmful exposure of piscivorous fish, wildlife, and humans to methylmercury (MeHg). Concentrations of total Hg in water, sediment, and soil were typical of those in forest ecosystems within the region, whereas MeHg concentrations and percent MeHg in these ecosystem components were markedly higher than values reported elsewhere in the western Great Lakes Region. Soils and sediment were Hg-enriched, containing approximately 4-fold more total Hg per unit of organic matter. We hypothesized that localized Hg enrichment was due in part to anthropogenic pollution associated with historic fur-trading activity. Bottom-up forcing of bioaccumulation was evidenced by MeHg concentrations in larval dragonflies, which were near the maxima for dragonflies sampled concurrently from five other national park units in the region. Despite its semi-remote location, GRPO is a Hg-sensitive landscape in which MeHg is produced and bioaccumulated in aquatic food webs to concentrations that pose ecological risks to MeHg-sensitive piscivores, including predatory fish, belted kingfisher, and mink. ... Larvae of the families Aeshnidae and Corduliidae were the most widely distributed dragonflies collected at GRPO, inhabiting all four stream sites and accounting for 64% of the 201 larvae sampled and analyzed (Table 4). Larvae from three other dragonfly families, including 22 cordulegastrids, 1 gomphid, and 50 libellulids, were found at one or two of the four sites. Mean concentrations of MeHg in larval dragonflies from the four stream sites ranged from 118 to 190 ng/g dry weight in aeshnids and from 136 to 185 ng/g in corduliids. Methylmercury accounted for more than 90% of the total Hg in dragonfly larvae for most taxa and stream sites. For example, mean %MeHg in larvae from the four stream sites ranged from 91% to 97% in corduliids and from 81% to 94% in aeshnids." 14958. Rosenthal, E. (2015): Seasonal variation in the shape of *Hetaerina americana*. Thesis - Honors College, Biology, Baylor University: (in English) ["The ability to fly strongly contributes to the success of insects. The adaptive nature of wing size and shape dictates much of the organism's success flying, both short-term (food and mate acquisition) and long-term (persistence of the species in the environment). Members of Order Odonata are among the most efficient and iconic fliers in the animal kingdom, and wing shape is among many factors contributing to their flight success. The quantitative science of morphometrics is the study and analysis of shape. My study takes a morphometric approach to investigate variation in wing shape for *Hetaerina americana*, a common species of damselfly in North America. Specifically, I focus on variation in wing shape between damselflies emerging in mid-spring after a winter-long larval development versus those emerging in late summer after a warmer, summer-long larval development. Analyses revealed that for both fore wings and hind wings winter developer wing shapes differ significantly from summer developer wing shapes. Fore wings vary in shape more distinctly by season than do hind wings. Summer developer fore wings are broader than those of winter developers, and summer developer hind wings are narrower. This variation in wing shape may be a consequence of seasonal circumstances (shorter, warmer development with a higher larval metabolic rate), or reveal an adaptive strategy for flight in air of varying temperatures. This latter strategy would indicate a genetic plasticity capable of producing wing shapes adaptive to seasonal variation." (Author)] Address: not stated

14959. Rychła, A. (2015): Die Niederschlesische Heide (Bory Dolnośląskie): ein Refugium für seltene Moorbibellen im Südwesten Polens? International Dragonfly Fund Report 83: 1-18. (in German, with English and Polish summaries) ["In 2014, Odonata species were investigated in selected habitats, especially in peat bogs, in the western part of the Lower Silesian Wilderness on the German-Polish border. Of particular interest were regionally rare and species protected by Polish law. A total of 39 dragonfly species were observed and for 26 the development was confirmed. There were four legally protected species: *Ophiogomphus cecilia*, *Aeshna subarctica*, *Leucorrhinia albifrons* and *L. pectoralis*, and one endangered species *Orthetrum coerulescens* – category NT in the area. Furthermore, first records for 14 species within the investigated UTM squares are provided. Further, for *O. coerulescens* and *Leucorrhinia rubicunda* historical observations from the field have been updated. The results show a significant dragonfly diversity in the studied areas. Especially valuable are the first records of *A. subarctica* in the field, however, they still require a confirmation of autochthony." (Author)] Address: Rychła, Anna, ul. 14961. Sánchez Herrera, M.; Kuhn, W.R.; Lorenzo-Carballa, M.O.; Harding, K.M.; Ankrom, N.; Sherratt, T.N.; Hoffmann, J.; Van Gossum, H.; Ware, J.L.; Cordero-Rivera, A.; Beatty, C.D. (2015): Mixed Signals? Morphological and molecular evidence suggest a color polymorphism in some Neotropical Polythore damselflies. *PLoS ONE* 10(4): e0125074. doi:10.1371/journal.pone.0125074: 24 pp. (in English) ["The study of colour polymorphisms (CP) has provided profound insights into the maintenance of genetic variation in natural populations. We here offer the first evidence for an elaborate wing polymorphism in the Neotropical damselfly genus *Polythore*, which consists of 21 described species, distributed along the eastern slopes of the Andes in South America. These damselflies display highly complex wing colours and patterning, incorporating black, white, yellow, and orange in multiple wing bands. Wing colours, along with some components of the male genitalia, have been the primary characters used in species description; few other morphological traits vary within the group, and so there are few useful diagnostic characters. Previous research has indicated the possibility of a cryptic species existing in *P. procera* in Colombia, despite there being no significant differences in wing colour and pattern between the populations of the two putative species. Here we analyse the complexity and diversity of wing colour patterns of individuals from five described *Polythore* species in the Central Amazon Basin of Peru using a novel suite of morphological analyses to quantify wing colour and pattern: geometric morphometrics, chromaticity analysis, and Gabor wavelet transformation. We then test whether these colour patterns are good predictors of species by recovering the phylogenetic relationships among the 5

species using the barcode gene (COI). Our results suggest that, while highly distinct and discrete wing patterns exist in Polythore, these "wingforms" do not represent monophyletic clades in the recovered topology. The wingforms identified as *P. victoria* and *P. ornata* are both involved in a polymorphism with *P. neopicta*; also, cryptic speciation may have taking place among individuals with the *P. victoria* wingform. Only *P. aurora* and *P. spateri* represent monophyletic species with a single wingform in our molecular phylogeny. We discuss the implications of this polymorphism, and the potential evolutionary mechanisms that could maintain it." 14966. Sondermann, M.; Gies, M.; Hering, D.; Schröder, M.; Feld, C.K. (2015): Modelling the effect of in-stream and terrestrial barriers on the dispersal of aquatic insect species: a case study from a Central European mountain catchment. *Fundamental and Applied Limnology / Archiv für Hydrobiologie* 186(1-2): 99-115. (in English) ["Worldwide, lotic ecosystems are heavily impacted by anthropogenic disturbance, leading to a significant decline in freshwater biodiversity. In recent years, increasing efforts have been directed towards the restoration and revitalization of disturbed streams and rivers to reverse this trend. Although it is widely acknowledged that species dispersal is the key to the recolonization of restored streams and rivers and ultimately to their ecological recovery, dispersal often remains unaddressed in restoration ecology. In this study, we present an approach to predict larval (aquatic) and adult (terrestrial) dispersal ranges of three lotic insect species (*Hydropsyche dinarica* [Trichoptera], *Calopteryx virgo* [Odonata] and *Dinocras cephalotes* [Plecoptera]) within one life cycle. The actual species' distributions (presence / absence) were obtained from a total of 1,198 sites evenly distributed within the Ruhr catchment, North Rhine-Westphalia, Germany. The predictions for aquatic and terrestrial dispersal were made for two scenarios: with and without dispersal barriers included in the predictive modelling. In-stream dispersal barriers included weirs, dams, culverts and impounded water bodies, whereas terrestrial barriers

were related to the stream corridor (degraded riparian vegetation) and different forms of land use (urban land use, coniferous and deciduous or mixed forest, open land, road infrastructure). We applied a least-cost modelling approach and combined each species' life-cycle-specific dispersal capabilities and the corresponding dispersal barrier's "friction" costs in a grid-based GIS model. Among the three model species, *H. dinarica* was the best disperser and was predicted to be able to reach between 81% (without barriers) and 67% (with barriers) of all river sections in the model catchment within one life cycle. Aerial (terrestrial) dispersal was by far the most important dispersal mechanism. For validation purposes, we conducted a logistic regression analysis to identify sample sites with environmentally suitable habitats. Within these sites that are not considered constrained by habitat limitations, the comparison of actual and predicted absences revealed a better match, if barriers were included in the dispersal models. At the same time the mismatch of actual absences and predicted presences decreased. Our results suggest that dispersal models can contribute to a better assessment of the potential recolonization of rivers. Yet, the dispersal of lotic insects may be considerably overestimated if dispersal barriers remain unaddressed." (Authors)] Address: Sondermann, M., Centre of Water & Environmental Research. 14973. Thamarai Selvi, V.P.; Merlin Dayana, L. (2015): Biodiversity of insects in sugarcane field at a Vadipatti, Tamil Nadu, India. *International Research Journal of Environment Sciences* 484: 74-79. (in English) ["Sugarcane is highly important cash crop and sugar production in the country mostly depends on this crop. Sugarcane is known to be attacked by about 200 species of insects

and non insects in India. The light trap collection yielded seven orders namely Odonata, Orthoptera, Hemiptera, Homoptera, Coleoptera, Lepidoptera, and Hymenoptera. Homoptera was the prominent order with 6 species. Insignificant values are observed with the help of Correlation and Regression. Coleoptera was the richer in terms of number of individuals (102) and Odonata was least recorded with less number of individuals (33). The present study reveals that the most of the light trap collected insects were pest of sugarcane agroecosystem. Many predators and parasite of the orders Odonata, Orthoptera, Hemiptera, Homoptera, Coleoptera, Lepidoptera and Hymenoptera were also found in sugarcane field at A.Vadipatti, Periyakulam Taluk, Theni District. Even though, many insects are found in the sugarcane agro ecosystem, many insects were found to be the pest of sugarcane crop. Odonata was the moderate order with 4 species. It contributes 33 insects that amount to 6.76% in the total entomofauna. The 6th fortnight collection yielded the maximum number of individuals that 8 during the second half of January 2013 with an average minimum temperature 27.5°C. This period experienced an average rainfall 1.4mm the Odonata population declined during first half of November 2012 with least number of individuals 3. This decline in Odonata population conceded with soar temperature maximum 29°C." (Authors)] Address: J.A. Autonomous College for Women, Periyakulam, Theni District, INDIA

14975. Therry, L.; Bonte, D.; Stoks, R. (2015): Higher investment in flight morphology does not trade off with fecundity estimates in a poleward range-expanding damselfly. *Ecological Entomology* 40: 133-142. (in English) ["(1.) Evolutionary increases in dispersal-related traits are frequently documented during range expansions. Investment in flight-related traits is energetically costly and a trade-off with fecundity may be expected during range expansion. (2.) However, in contrast to wing-dimorphic species, this trade-off is not general in wing-monomorphic species. In the absence of a dispersal--fecundity trade-off, an increased investment in clutch size at the expansion front is expected possibly at a cost of reduced offspring size. (3.) The study evaluated investment in female flight morphology and fecundity-related traits (clutch size, hatchling size) and potential trade-offs among these traits in replicated populations of the poleward range-expanding damselfly *Coenagrion scitulum*.

(4.) Females at the expansion front had a higher relative thorax length, indicating an increased investment in flight; this can be explained by spatial sorting of dispersal ability or in situ natural selection at the expansion front. Edge females produced larger hatchlings, however, this pattern was totally driven by the population-specific thermal larval regimes and could not be attributed to the range expansion per se. By contrast, clutch sizes did not differ between core and edge populations. There was no signal of a dispersal--fecundity trade-off either for a trade-off between clutch size and hatchling size. (5.) These results indicate that evolution of a higher dispersal ability at the expansion front of *C. scitulum* does not trade off with investment in fecundity, hence a dispersal--fecundity trade-off is unlikely to slow down range expansion of this species." 14977. Thornton, J.L.; Switzer, P.V. (2015): Factors affecting the spatial distribution of oviposition sites for tandem Black Saddlebags Dragonflies (Odonata: Libellulidae). *Journal of Insect Science* 15: 5pp. (in English) ["Oviposition site location may be affected by (1) factors influencing the costs and benefits to the offspring (e.g., resource availability, competition, predation risk) and (2) factors influencing the costs and benefits to the female (e.g., predation risk or mate harassment). In cases in

which both the male and female are involved in locating a site, costs and benefits may differ for each parent and the resulting oviposition site location may represent the outcome of selection pressures on one or both of them. We studied oviposition behaviour in *Tramea lacerata*, a species in which the male and female typically remain together (i.e., in tandem) while travelling among potential oviposition locations. Oviposition sites tended to be away from pond shoreline at the outer edge of the vegetation on the water's surface. We found that tandems distributed their oviposition locations widely around the pond, and interactions with other dragonflies (typically other *T. lacerata*, either territorial males or tandems) led to a larger distance between consecutive oviposition locations. Interestingly, for 10% of the tandems, the female became separated from the male and oviposited solitarily multiple times. These solitary females spent significantly less time and travelled significantly smaller distances between successive oviposition sites than when in tandem. Our results indicate that while some aspects of oviposition behaviour and site selection may be consistent between the male and female (e.g., the characteristics that make a site suitable), other aspects, such as the distribution of sites, may be a result of a differing benefits and costs for the two sexes, perhaps as a consequence of potential sperm competition." 14978. Tiple, A.D.; Koparde, P. (2015): Odonata of Maharashtra, India with notes on species distribution. *J. Insect Sci.* (2015) 15(1): 47; DOI: 10.1093/jisesa/iev028: 10 pp. (in English) ["Maharashtra, the third largest state of India, harbours a variety of land-use and occupies six biogeographic provinces. We carried out Odonata surveys in Maharashtra during 2006–2014. Compilation of all these studies along with other authenticated records resulted in a checklist of 134 species of Odonata belonging to 70 genera representing 11 families. The highest numbers of species were recorded from the Libellulidae (48 species) and Gomphidae (22 species) families. A previous study had reported 99 species of Odonata from the Maharashtra state considering records from early 1900's to 2012. Our observations across the state add 33 species to this list. Maharashtra forms a unique source of Odonata diversity and our observations support the importance of this region in providing valuable habitats for Odonata. Here, we discuss several of the new records, how global surveys might help fill the local gap in species distributions, how secondary data deposited through crowd-sourcing can help and what it offers to conservation." 14980. Tüzün, N.; Debecker, S.; Op de Beeck, L.; Stoks, R. (2015): Urbanisation shapes behavioural responses to a pesticide. *Aquatic Toxicology* 163: 81-88. (in English) ["Highlights: •We tested for effects of urbanisation on vulnerability to chlorpyrifos in *Coenagrion puella*. •Behavioural responses to chlorpyrifos differed between urban and rural populations. •Exposed rural larvae decreased activity and feeding at 20 °C and 24 °C. •Exposed urban larvae increased activity and only reduced feeding at 24 °C. •Results suggest local adaptation to higher pesticide levels in urban populations. The degree of urbanisation is rapidly increasing worldwide. Due to anthropogenic impact, urban populations are exposed to higher levels of contaminants and higher temperatures. Despite this, urbanisation is a largely overlooked spatial component in ecotoxicology. We tested in a common garden rearing experiment whether replicated urban and rural populations of *C. puella* differ in their vulnerability to sublethal levels of a widespread pesticide, chlorpyrifos, in terms of ecologically relevant behaviours (exploration behaviour, activity, boldness and food intake), and to what extent these patterns are affected by temperature (20 and 24 °C). Except boldness, all behaviours were affected by previous pesticide exposure. While the pesticide did not affect exploration behaviour at 20 °C, it was associated with increased exploration at 24 °C, which may reflect an increased toxicity of chlorpyrifos at higher temperatures. Importantly, rural and urban larvae showed consistently different, sometimes even opposite behavioural responses to pesticide exposure. When exposed to the pesticide, rural larvae decreased activity and food intake at both temperatures; urban larvae instead increased activity at both temperatures and only reduced food intake at the high temperature. This suggests that urban larvae were less affected by the pesticide, which would be consistent with a scenario of local adaptation to higher contaminant levels. Our results highlight that urbanisation may be an important factor to arrive at a spatially explicit

ecological risk assessment, and may be an ignored reason why studies on the same species may generate widely different vulnerabilities to pesticides." 14986. Whatley, M.H.; van Loon, E.E.; Cerli, C.; Vonk, A.; van der Geest, H.G.; Admiraal, W. (2014): Linkages between benthic microbial and freshwater insect communities in degraded peatland ditches. *Ecological Indicators* 46: 415-424. (in English) ["Many wetlands are heavily modified and identifying the environmental drivers of indicator groups like aquatic insects is complicated by multiple stressors and co-varying environmental factors. Yet, incorporating data from other biological groups, such as microbial communities, potentially reveals which environmental factors are underpinning insect community composition. In the present study we investigated the application of benthic microbial community composition, as determined by phospholipid fatty acid (PLFA) analysis, alongside aquatic insect data in 25 peatland ditches in the province of North Holland, The Netherlands. We applied clustering and principal component analysis to a matrix of 26 PLFAs to group ditches by the microbial community. Generalized linear models were used to examine correlations between microbial PLFAs, insects, vegetation (emergent and submerged) and abiotic factors. The ratio of heterotrophic (e.g. sulphate re-

ducing bacteria) to autotrophic (e.g. algae and cyanobacteria) derived PLFAs could be estimated as the ratio between saturated and branched to monounsaturated and polyunsaturated fatty acids (SB/MP). SB/MP was correlated with insect community composition, differences in water chemistry (in particular bicarbonate, sulphate and nutrients) and vegetation cover in the ditches. Moreover, ditches distinguished by their microbial communities differed in the number of insects they supported with differences most pronounced for Odonata, Trichoptera and Chironomus larvae. This study demonstrates that integrating microbial and aquatic insect community data provides insight into key environmental drivers in modified aquatic ecosystems and may facilitate the development of remediation strategies for degraded wetlands. Linkages between benthic microbial and freshwater insect communities in degraded peatland ditches." 14987. Wiles, C.M.; Bolek, M.G. (2015): Damselflies (Zygoptera) as paratenic hosts for *Serpinema trispinosum* and its report from turtle hosts from Oklahoma, USA. *Folia Parasitologica* 62: 019, 2015, 8 pp (in English) ["Third-stage larvae of the nematode *Serpinema trispinosum* (Leidy, 1852) were collected from the midgut of four of five species of adult damselflies (Zygoptera) from a non-irrigated restored semipermanent wetland located in Stillwater, Oklahoma, USA. Of the four infected damselfly species, prevalence and mean abundance was highest for the southern spreadwing, *Lestes disjunctus australis* (10%, 0.2 ± 0.8) and lowest for the familiar bluet, *Enallagma civile* (Hagen) (2.5%, 0.04 ± 0.3); whereas mean intensities were lowest for the citrine forktail, *Ischnura hastata* (1.5 ± 0.5) and the eastern forktail, *Ischnura verticalis* (1.0 ± 0). This is the first record of larvae of *S. trispinosum* from damselflies. *Serpinema trispinosum* adults have been reported from 18 species of North and Central American freshwater turtles, whereas microcrustaceans such as copepods serve as intermediate hosts and snails, fish and amphibians serve as paratenic hosts in this nematode's life cycle. However, dietary studies of the 18 species of freshwater turtles reported as definitive hosts for *S. trispinosum* indicate that aquatic insects including damselflies are more commonly reported in turtle diets than are fish or amphibians. Additionally, unlike snails and amphibians, larval damselflies predominantly feed on microcrustaceans, and our observation of *S. trispinosum* infecting damselflies may reflect the importance of these insects as paratenic hosts. In the present study, we provide new host information and measurements for third-stage larvae of *S. trispinosum* from damselfly hosts along with measurements for adult male and female *S. trispinosum* from turtle hosts from Oklahoma, USA." 14988. Worthen, W.B.; Horacek, H.J. (2015): The distribution of dragonfly larvae in a South Carolina stream: Relationships with sediment type, body size, and the presence of other larvae. *J. Insect Sci.* 15(31): DOI: 10.1093/jisesa/iev013: 7 pp. (in English) ["Dragonfly larvae were sampled in Little Creek, Greenville, SC. The distributions of five common species were described relative to sediment type, body size, and the presence of other larvae. In total, 337 quadrats (1m by 0.5 m) were sampled by kick seine. For each quadrat, the substrate was classified as sand, sand-cobble mix, cobble, coarse, or rock, and water depth and distance from bank were measured. Larvae were identified to species, and the lengths of the body, head, and metafemur were measured. Species were distributed differently across sediment types: *Progomphus obscurus*, were common in sand; *Cordulegaster maculata*, preferred a sand-cobble mix; *Ophiogomphus mainensis*, preferred cobble and coarse sediments; *Boyeria vinosa*, preferred coarse sediments; and *Stylogomphus albistylus*, preferred coarse and rock sediments. *P. obscurus* and *C. maculata* co-occurred more frequently than expected by chance, as did *O. mainensis*, *B. vinosa*, and *S. albistylus*. Mean size varied among species, and species preferences contributed to differences in mean size across sediment types. There were significant negative associations among larval size classes: small larvae (<12 mm) occurred less frequently with large larvae (>15 mm) than expected by chance, and large larvae were alone in quadrats more frequently than other size classes. Species may select habitats at a large scale based on sediment type and their functional morphology, but small scale distributions are consistent with competitive displacement or intraguild predation." 14989. Xie, C.-M.; Huang, W.-X. (2015): Vortex interactions between forewing and hindwing of dragonfly in hovering flight. *Theoretical & Applied Mechanics Letters* 5(1): 49 -54. (in English) ["Two tandem flapping wings in viscous flow were modelled by using the immersed boundary method for exploration of the aerodynamics of dragonfly in hovering flight. Interaction between the forewing and the hindwing, and its effect on the lift forces, were examined by varying the phase difference of the wing motions and the inter-distance of the two wings. Two vortex interaction modes were identified at different phase differences and inter-distances, which give rise to significant variations of the lift forces. The first interaction mode increases the lift of the forewing and the second one enhances the lift of the hindwing. The two modes occur at different time during a flapping period and have different influence on the lift of wings as the phase difference varies." (Authors)] Address: Xie, C.-M., Sino-French

14990. Xu, Q.-H. (2015): Description of the final stadium larva of *Heliocypha perforata perforata* (Percheron), with discussion of the taxonomic characters of the larvae of the genus *Heliocypha* Fraser (Odonata: Zygoptera: Chlorocyphidae). *Zootaxa* 3926(1): 137-141. (in English) ["The final stadium larva of *Heliocypha perforata perforata* is described and illustrated for the first time. It is characterized by having a row of filiform setae present laterally on distal half of prementum, 6-7 setae on the outer side of palpal lobe, very long lateral gills and distinct abdominal colour pattern. The taxonomic characters of the larvae of the genus *Heliocypha* are discussed and summarized. *Heliocypha* larvae share a high similarity with *Rhinocypha* in general appearance and cannot be clearly distinguished from the latter in structure." (Author)] Address: Xu, Q.-H., Department of Garden and Horticulture, Zhangzhou City University, Zhangzhou, Fujian 363000, PR China. E-mail: qihanxu@aliyun.com

14991. Yeh, W.-C.; Lee, I.-L.; Wong, K.-C. (2015): Description of *Sarasaeschna kaoi* sp. nov. in Taiwan, with notes on the proposed differentiating characters of the pyanan-group (Odonata, Aeshnidae). *Zootaxa* 3926(1): 122-128. (in English) ["*Sarasaeschna kaoi* sp. nov. collected from Yuli, Hualien County in eastern Taiwan, is easily distinguished from all known congeners by its male having short and straight cerci. Judging from male penile structure, it is considered to belong to the pyanan-group of species and resembles in general appearance the Chinese *S. zhuae* described from Fujian. The only known habitat of *S. kaoi* is a muddy and grassy swamp in natural evergreen forest. The diagnostic characters of the pyanan-group proposed by Karube & Yeh are also discussed." 14992. Zheng, D.; Zhang, H.; Zhang, Q.; Li, S.; Wang, H.; Fang, Y.; Liu, Q.; Jarzembowski, E.A.; Yan, E.; Wang, B. (2015): The discovery of an Early Cretaceous dragonfly *Hemeroscopus baissicus* Pritykina, 1977 (Hemeroscopidae) in Jiuquan, Northwest China, and its stratigraphic implications. *Cretaceous Research* 52, Part B: 316-322. (in English) ["The Early Cretaceous dragonfly *Hemeroscopus baissicus* Pritykina is reported for the first time from the Jiuquan Basin, Gansu Province, Northwest China based on adult wings. These wings are different from those from other localities in two aspects: the oblique crossvein 'O' is 3 or 4 cells distal of the subnodus; the wing size is much smaller (30–42 mm in length for forewings). These differences are considered to be intraspecific variations, based on which diagnoses of the genus *Hemeroscopus* and the family Hemeroscopidae are revised. The discovery of *H. baissicus* in Jiuquan suggests that the Zhonggou Forma-

tion may be correlated with the Fuxin Formation in Liaoning Province, the Lushangfen Formation in western Beijing, and the Dongmyeong Formation in southern Korea. A possible migration path of the dragonfly is indicated that it initially appeared in Transbaikalia in the Aptian, migrated southwestwards to Mongolia in the Aptian or early Albian, and then southwestwards to northwest China, southeastwards to northeast China, and southern Korea in the early Albian." (Authors)] Address: Zheng, H., State Key Laboratory of Palaeobiology and Stratigraphy, Nanjing Institute of Geology and Palaeontology, Chinese Academy of Sciences, 39 East Beijing Road, Nanjing 210008, China. 14993. Zhu, G.-p.; Yu, X.; Bu, W.j. (2015): Ecology and conservation of *Pseudolestes mirabilis* (Odonata: Zygoptera), a damselfly endemic to Hainan Island of China. *Entomological Science* 18(1): 123-129. (in English) ["Although some efforts have addressed oriental dragonfly conservation, knowledge on the ecology and geographic distribution of such dragonflies remains scant. *P. mirabilis* is endemic to Hainan Island of China. This damselfly was recommended by the International Union for the Conservation of Nature to be of priority for further study and conservation. In this work, we use ecological niche modelling techniques to estimate the dimensions of the realized niches of this damselfly and to predict its potential distribution. Our findings suggest that the phoenix damselfly possessed a small climate space characterized by low temperature and high precipitation. Highly suitable areas are mainly distributed in the low-altitude regions of southern central tree-covered mountains in Hainan. Caution is warranted when considering the potential habitat loss attributed to human activity and climate change." (Authors)] Address: Bu, W.j., College of Life Sciences, Nankai University, Tianjin, China. E-mail: wenjunbu@nankai.edu.cn

Many thanks to all who contributed to this issue of OAS! A special thank to Paweł Buczyński for multiple help, and Andreas Martens, Asmus Schröter, Cédric Vanappelghem, Geert de Knijf and Bernd Kunz for contributing papers to this issue.

Last words ...

Going on with a project or task, requires a minimum of feedback. Compiling and preparing the abstracts of OAS requires on an average of 15 minutes per abstract. That is a lot of time considering that in the meantime nearly 16000 abstracts have been arranged. There have been less than the ever same 5-10 people – and I am more than thankful for their encouragement to go on with abstracting! – giving this feedback. More, it was and is frustrating to see that those responsible of WDA never engaged in this journal, even didn't inform the members via a simple e-mail when a new issue was ready, in spite we several times asked them to do so. In the beginning of OAS, Jill Silsby and the board of WDA supported the editors of OAS, but the new generations of boards obviously forgot, OAS was a journal of WDA too.

A journal without feedback is probably without benefit for the majority of readers, and will have to be ceased. And I do so with this double issue. This must not be the final end. But, any restart will depend on private priorities. Hope, there will be a few odonatologists missing OAS...

I am very thankful to Jill and Philip Corbet for all the encouragements without we never would have started the journal. I am thankful to Martin Lindeboom and Klaus Reinhardt for all the years of assistance, and especially to Milen Marinov. Thanks to Pawel Buczynski, who checked the spelling of Slavic languages. And thanks to all who provided papers to be considered as abstract.

14994. Hutchinson, J.M.C. (1998): Factors influencing the surface fauna of inland blue holes on South Andros, Bahamas. *Cave and Karst Science* 25(2): 83-92. (in English) ["We surveyed the macrofauna (particularly insects, molluscs and birds) of the surface waters of a series of inland, mostly anchialine, blue holes (flooded caves and associated lakes). The number of species was small, but the fauna varied considerably between holes. The following factors are evaluated as causes of these patterns: isolation and past inundation of Andros island, difficulty of dispersal between holes, topography (size of hole, water depth, whether ringed by cliffs), the surrounding vegetation, water quality (salinity, aeration, nutrients), tidal influence, human disturbance and pollution. Conservation issues are discussed, but generally the surface fauna is shared with far more extensive habitats on Andros. The same conclusion is drawn about the fauna of two subaerial caves associated with blue holes. A special study was made of Odonata. Around most holes we searched for exuviae, in some holes we found live nymphs, and we also noted whether adults were ovipositing. From this evidence at least seven species were breeding in blue holes: *Ischnura ramburi*, *Neoerythromma cultellatum*, *Anax junius*, *Brachymesia furcata*, *Erythrodiplax berenice*, *Macrodiplax balteata*, *Tramea onusta*. Table 1 shows the strong effect of salinity on diversity. *E. berenice* could breed even in the most saline holes, but the next two most tolerant species were not found breeding in salinities over 9.8 ppt. No dragonflies were observed around Swimming Hole and Co-op Hole despite each being visited twice in suitable conditions. The probable reason is that both lack shallows. The richest blue hole was Battle Hole (12 species), the least saline of the fracture-line holes, with extensive shallows, much algae and extensive overhanging vegetation. In comparison, several of the quarries filled with shallow fresh or weakly brackish water had 14 or

15 species frequenting them. In total we observed 26 species on South Andros, with indications of breeding for 16." (Author)] Address: Hutchinson, J.M.C., School of Biological Sciences, University of Bristol, Woodland Road, Bristol, BS8 1UG, UK. E-mail: John.Hutchinson@bristol.ac.uk

14995. Davies, N.M.; Norris, R.N.; Thoms, M.C. (2000): Prediction and assessment of local stream habitat features using large-scale catchment characteristics. *Freshwater Biology* 45: 343-369. (in English) ["(1.) Knowledge of what a habitat should be like, in the absence of the effects of human activities, is fundamental to local stream habitat assessment. It has been suggested that stream habitats are influenced by large-scale catchment features. This study aimed to identify these relationships so that local-scale habitat features could be predicted from larger-scale characteristics. (2.) Fifty-one reference sites from the Upper Murrumbidgee River catchment, south-eastern Australia, were classified on the basis of the local features of their stream habitat. Large-scale variables, namely catchment area, stream length, relief ratio, alkalinity, percentage of volcanic rocks, percentage of metasediments, dominant geology and dominant soil type, provided sufficient information for classifying 69% of reference sites into appropriate reference site groups. (3.) A model created using these large-scale catchment variables was able to predict the local habitat features that were expected (E) to occur at a site in the absence of the effects of human activities. These were compared with observed (O) local habitat features to provide an observed-to-expected (O/E) ratio, an assessment score of the habitat at a site. The departure of this ratio from 1 enables identification of those sites that may be impacted. A list of habitat features that are expected at a site can provide targets for habitat restoration or enhancement. (4.) For impacted sites, when habitat assessment from the habitat predictive model was compared with biological assessment from the Australian River Assessment System (AUSRIVAS) predictive model, it was possible to identify whether habitat degradation or water quality degradation was the cause of biological impairment. Such assessment may make it possible to identify rehabilitation goals relevant to the biota." 14997. Purse, B.V. (2001): The ecology and conservation of the Southern Damselfly (*Coenagrion mercuriale*). PhD Thesis, University of Liverpool: 336 pp. (in English) ["This thesis presents an autecological study of *C. mercuriale*), a

rare insect that is on the northern edge of its range in Britain. The primary aims of this study were to examine habitat use (at both broad and small scales) and to investigate other aspects of development and behaviour in *C. mercuriale* with a view to devising appropriate management practices for the species. *Coenagrion mercuriale* was found to be restricted in its national and global distribution and was estimated to have undergone more than a 30% decline in its British distribution since 1985. It is a stenotopic species being highly sensitive to a number of habitat factors at both broad and small scales of habitat use. A requirement for a thermally advantageous microclimate was reflected in broad scale habitat use (e.g. use of shallow, sun-exposed, permanently flowing waterbodies indicated by perennial, herbaceous, aquatic vegetation) and in habitat use for oviposition and emergence by *C. mercuriale*. This species was found to have a semi-voltine life cycle in Britain, with a shorter larval growth period and flight period than in mainland European populations. Seasonal regulation is probably achieved in Britain by a facultative autumn diapause in the penultimate larval instar. In field experiments, mature adults of *C. mercuriale* exhibited a relatively low rate of emigration and travelled relatively short distances over non-habitat. However, examination of the distances between extant sites suggest that such rates of dispersal may be sufficient to promote founding and persistence of local populations within four large clusters of populations in Britain. Weather conditions, namely temperature were found to effect daily emergence, activity (including reproductive activity) and mature adult survival. Thus, in common with other thermophilic insects, *C. mercuriale* was found to be limited by temperature in many respects on the edge of its range. The requirement for a thermally advantageous microclimate restricts this species to an early successional stage in both its biotopes and a range of management practices are suggested for maintenance of such stages on *C. mercuriale* sites in Britain. Since rates of dispersal seemed highly dependent on landscape structure, management to facilitate movement between sites across non-habitat was also suggested." 14998. U.S. Fish and Wildlife Service; Zercher, D. (2001): Hine's Emerald Dragonfly recovery plan. Fort Snelling, MN: 120 pp. (in English) ["Current Status: Hine's Emerald Dragonfly (*Somatochlora hineana*), was listed as endangered in January 1995. Extant *S. hineana* populations are currently known to persist in Illinois, Wisconsin, Michigan, and Missouri. The Illinois population is the most genetically diverse, and the Wisconsin populations are the largest and presumably most secure. Information on the status of the Michigan and Missouri populations is limited because of their recent discoveries. Historically known from Ohio and Indiana, it is thought to be extirpated from these states. Habitat Requirements and Limiting Factors: *S. hineana* occupies marshes and sedge meadows fed by calcareous groundwater seepage and underlain by dolomite bedrock. In general, these

areas are characterized by the presence of slowly flowing water and nearby or adjacent forest edges. Known occupied habitats are currently restricted to the lower Des Plaines River valley, in Illinois; northeastern Door County and Cedarburg Bog, Wisconsin; areas of the Hiawatha National Forest, in the Upper Peninsula of Michigan, three areas in the Lower Peninsula of Michigan, and at three fens in Missouri. Loss of this already rare and restricted habitat to agriculture, commercial and industrial development is the primary cause of the species' decline. Loss of remaining habitat from the same pressures, combined with successional change in the existing habitats and disruption of ecological and hydrological processes, are threats to surviving populations. Recovery Objectives: The objective of this recovery plan is to restore *S. hineana* to viable populations so that it may be removed from the Federal list of Endangered and Threatened Wildlife and Plants. Recovery Criteria: Each of the two Recovery Units contains a minimum of three populations composed of at least three subpopulations. Each subpopulation contains a minimum of 500 reproductive adults for 10 consecutive years. Within each subpopulation, there are at least two breeding habitat areas, each fed by separate seeps and/or springs. For each population, the habitat supporting at least three subpopulations should be legally or formally protected and managed for *S. hineana*, using long-term protection mechanisms such as watershed protection, deed restrictions, land acquisition, or nature preserve dedication. In addition, mechanisms protecting the up gradient groundwater watershed should also be in place." 14999. Domek, P.; Joniak, T. (2002): Seasonal changes of macrobenthos under physiological and chemical water conditions in humic lakes. *Materialy 9 Ogólnopolskich Warsztatów Bentologicznych*. - [Abstracts of the 9th Polish Workshop of Benthology]. Mikolaj: 5. (in Bilingual in Polish and English) [Verbatim: The investigation on taxonomic content, density and dominance structure of benthos organisms was carried out in spring and autumn in 1999-2000. Three humic lakes of Drawieński National Park were researched; littoral as well as profundal zone were taken into account. Physico-chemical properties of the lake water were evaluated on the basis of field as well as laboratory analyses. Amount of humic substances (HS) dissolved in the water made it possible to classify Glodne Lake III (GL III) as a polihumic lake, Glodne Lake IV (GL IV) as a mesohumic, and Piaseczno Male Lake (PML) as an oligohumic lake (Eloranta 1999). HS influence the water colour, limit the range of euphotic layer, lower the pH and fix numerous organic as well as inorganic compounds into complexes that are difficult to decomposition. Concentrations of the dissolved reactive phosphorus (DRP) that is easily assimilated by the organisms, were in comparison to the amount of total phosphorus lower than usually associated with this type of lakes. Average annual concentrations of the DRP totaled not more than 0.01

mg P l⁻¹; moreover, in PML the amount was average by a half lower than in other lakes. Concentrations of phosphorus undergo seasonal changes, especially in spring and autumn which is the time of lake water mixing. The modification of settlement conditions caused by the presence of HS, formed living conditions of benthos organisms the lakes. 28 taxons belonging to 10 systematic groups were found. PML and GL IV turned out to be the most rich in fauna (respectively 19 and 18 taxons). In the third of the investigated lakes 12 taxons of macrozoobenthos were found. In GL IV the number of taxons was much higher in autumn than in spring, and in the other lakes their number was similar regardless to the seasonal changes. The most qualitatively differentiated groups were Odonata: *Cordulia aenea*, *Enallagma cyathigerum*, *Ischnura elegans*, *Leucorrhinia* sp., *Pyrrhosoma nymphula* and *Somatochlora metallica*. Of all the other groups of insects only Ephemeroptera, Hirudinea and Coleoptera were represented by more than one taxon. In GL III the most numerous were Diptera (37%) and Ephemeroptera (33%), and the contribution of organisms of other groups, with the exception of Trichoptera, totaled less than 10%. In GL IV the dominance of Diptera was marked even more clearly (54%), and the second numerous were Hydracarina (22%). In PML Diptera constituted a large majority (80%) of macrozoobenthos and contribution of other groups, with the exception of Ephemeroptera, was minimal. Concentration of macrozoobenthos in littoral zone was mostly higher than in profundal and totaled from 2070 ind. m² in spring to 2438 ind. m² in autumn in GL IV, and in PML from 1426 ind. m² in spring to 2714 ind. m² in autumn. In profundal zone of GL III macrozoobenthos was not found. Altogether, in profundal zone 3 of all the 28 taxons were found.] Address: not stated

15003. Bromham, L.; Woolfit, M. (2004): Explosive radiations and the reliability of molecular clocks: Island endemic radiations as a test case. *Syst. Biol.* 53(5): 758-766. (in English) ["The reliability of molecular clocks has been questioned for several key evolutionary radiations on the basis that the clock might run fast in explosive radiations. Molecular date estimates for the radiations of metazoan phyla (the Cambrian explosion) and modern orders of mammals and birds are in many cases twice as old as the palaeontological evidence would suggest. Could some aspect of explosive radiations speed the molecular clock, making molecular date estimates too old? Here we use 19 independent instances of recent explosive radiations of island endemic taxa as a model system for testing the proposed influence of rapid adaptive radiation on the rate of molecular evolution. These radiations are often characterized by many of the potential mechanisms for fast rates in explosive radiations — such as small population size, elevated speciation rate, rapid rate of morphological change, release from previous ecological constraints, and adaptation to new niches — and represent a wide variety of species, islands, and genes. However, we find no evidence of a consistent increase in rates in island taxa compared to their mainland relatives, and therefore find no support for the hypothesis that the molecular clock runs fast in explosive radiations." 15007. Rouquette, J.R. (2005): Conservation requirements of the Southern Damselfly in chalkstream and fen habitats. *Science Report SC000017/SR*. Environment Agency, Rio House, Waterside Drive, Aztec West, Almondsbury, Bristol, BS32 4UD: V, 160 pp. (in English) ["Background: This report presents the findings of a PhD study investigating the ecology and conservation requirements of *C. mercuriale* in chalkstream and fen habitats in the UK. *C. mercuriale* is a species of conservation concern. Its status in Europe is considered to be 'very vulnerable' and it is threatened over much of its range. It is listed on the EC Habitats and Species Directive and is the only species of dragonfly or damselfly currently given priority status in the UK Biodiversity Action Plan. Further research into the damselfly's ecological requirements was identified as a key requirement in the Species Action Plan, published in 1995. Since that time, a number of studies have been undertaken, including a doctoral thesis on the ecology of the species in heathland streams (Purse 2001, and published as R&D Technical Report W1-021/TR). However, little work has been carried out on *C. mercuriale* in chalkstream and fen habitats in the UK and so important gaps remain in our knowledge of this species. Main objectives: The primary aim of this study was to examine the ecology and habitat requirements of this species in its chalkstream and fen habitats. It is hoped that the study will provide a basis for further conservation efforts, by guiding habitat management plans, informing conservation strategies and suggesting targets for surveillance and monitoring programmes. Fieldwork was performed primarily in the Itchen and Test Valleys in Hampshire (southern England), but also in fen habitat in Oxfordshire and Anglesey. Results: A large multi-site mark-release-recapture study revealed that *C. mercuriale* was extremely sedentary, with dispersal only occurring between adjoining

sites. The median net lifetime movement was 31.9 m and lifetime movements of greater than 500 m were rare. Factors affecting movement are examined and evidence of inverse density dependent movement is provided. It is argued that this latter finding, together with the short distances moved, has profound consequences for the population dynamics and conservation of this species. Adult *C. mercuriale* density and movement were analysed in relation to habitat variables and local population size. Mean adjacent population density was the single most important factor determining density. However, the species was also shown to be associated with a number of habitat features, the most important of which were: a channel substrate consisting primarily of silt, wide underwater ledges (berms), in-channel Conservation requirements of *C. mercuriale* in chalkstream and fen habitats emergent dicots, and bankside monocots. The presence of trees was negatively associated with damselfly density. *C. mercuriale* larvae were found to occur more often and in greater abundance at sites that contained abundant emergent dicots, particularly in smaller, more marginal channels with slow flow. They were rarely found in areas with much tree cover and were more abundant in locations where the banksides were open to grazing and with gentle or stepped bank profiles. *Apium nodiflorum* (fool's water-cress) and *Rorippa nasturtiumaquaticum* (water-cress) were found to be particularly important. Furthermore, they were associated with certain macroinvertebrate taxa that were indicative of well-vegetated, moderate to slow flowing waterbodies, with a predominantly silty substrate. Habitat requirements of adults and larvae have been found to be similar, although larvae were found in greatest abundance in habitats that were slightly further along the successional sequence than those favoured by adults. The nighttime roosting location of adult *C. mercuriale* has also been examined and it has been established that adults are strongly associated with two tussock-forming monocots, *Juncus inflexus* (hard rush) and *Deschampsia cespitosa* (tufted hair grass). Differences in the abundance of these plants have been shown to result in large differences in the number of *C. mercuriale* roosting in different parts of the study site. Conclusions and recommendations: It is concluded that loss of habitat, alterations to management on remaining sites and fragmentation of a once continuous network of sites, are likely to have been the driving forces behind the decline of this species, and that these remain the greatest threats to its continued existence. It is argued that successful conservation of *C. mercuriale* will involve active management of existing sites, together with the creation (or recreation) of a series of new sites to reconnect populations. Recommendations regarding the monitoring, conservation and management of *C. mercuriale* are presented and include: • New habitat should be created within 500 m to 1 km of existing sites, to create a series of 'stepping-stones' that would rejoin existing populations. • Sluice gates should be installed at some sites to enable proper control over water flow. New ditches created should be shallow and slow flowing throughout, or have ample shallow margins. Bank profiles should be shallow or stepped. • Ditch management operations should be carried out every few years on existing

sites to prevent excessive siltation and vegetation choking the channels. Work should be performed on short sections of ditch on rotation or on one side of the channel only. In all deeper channels shallow berms should be created during dredging work. • Banksides should be lightly grazed by cattle right to the water's edge. Extensive shading should be avoided." (Author)] Address: Rouquette, J.R., University of Liverpool, Liverpool, L69 3BX, UK

15008. Terzani, F.; Marconi, A. (2005): Odonati del Trentino-Alto Adige e del Cadore (Italia settentrionale) (Odonata). *Onychium* 3: 1-10. (in Italian, with English summary) [Dragonflies from Trentino-Alto Adige and Cadore (Northern Italy). A total of 575 specimens belonging to 18 genera and 32 species was collected in 53 stations of Trentino-Alto Adige and Cadore. *Erythromma viridulum* is new for Cadore.] Address: Terzani, F., Museo di Storia Naturale dell'Università di Firenze, sezione di Zoologia "La Specola", Via Romana 17, I-50125 Firenze, Italy. 15009. Garzon Sanabria, C. (2006): Caracterización de la fauna de Odonata (Insecta) en el área metropolitana de Bucaramanga/Santander. Tesis de Pregrado. Universidad Industrial de Santander. Bucaramanga: 41 pp. (in Spanish, with English summary) ["Characterization of the fauna of Odonata (Insecta), in the metropolitan area of Bucaramanga-Santander. - Naiad and adult specimens of the Order Odonata were collected during August 2005 to March 2006 taking into account the climatic regime. As a result, a total of 700 specimens distributed in seven families, 27 genera and 52 species were obtained, representing 22% of the Odonata fauna recorded for the country. *Anax amazili* is reported for Colombia for the first time. Correlation found between species collected as naiads and as adults per sampling site was not complete. Shannon Weiner's Indices of diversity (Fairness), Margalefs species richness, Berger Parker Dominancy, and Jaccard's similarity coefficient were calculated in order to determine a possible relationship between the dragonfly community and the ecological state of the ecosystems. A test of correlation of Mantle cloth between the composition of species in each station and the distance in Kilometers among them, was made. The communities of dragonflies were found to respond to conditions particular to each station, which could be attributed to the present fragmentation effects in the study area, and to the intraspecific competition (for territory, mate, food) characteristic of this order." 15012. Contreras-Gardun o, J.; Buzatto, B.A.; Abundis, L.; Nájera-Cordero, K.; Córdoba-Aguilar, A. (2007): Wing Colour Properties do not Reflect Male Condition in the American Rubyspot (*Hetaerina americana*). *Ethology* 113: 944-952. (in English) ["Adult males of *H. americana* dispute riverine territories where females arrive to mate. On the wing basis, these males bear a red pigmentation spot whose area correlates with territorial disputes and mating rate: males with larger spots are more successful. This is explained by the fact that spot size correlates with fat muscular reserves which fuel flight during territorial intrusions. To further our understanding of sexual selection acting on the spot, here we have examined possible differences in three spot colour properties (red chroma, hue and brightness) in three distinct adult male ages [young, middle-aged (when males are more likely to defend a territory) and old], social status (territorial and non-territorial in middle-aged males), and under two potentially, energetically and costly situations: when faced with an immune challenge [comparing a nylonimplanted male group vs. a non-implanted male group in two ages, teneral (previous to colour formation) and middle-aged] and low diet levels (comparing a male set of middle-aged animals that received food ad libitum vs. a male set that received no food). Our results indicate no change in colour properties across any of these comparisons. Taken together, these and previous results suggest that only spot size but not the spot characteristics we measured here, is sexually selected in males of this species at least in terms of pre-copulatory male-male competition. That some of these colour properties have been related to male condition in other calopterygid damselflies cannot be generalized to the *H. americana*." 2009

15017. Gillies, C.L.; Hose, G.C.; Turak, E. (2009): What do qualitative rapid assessment collections of macroinvertebrates represent? A comparison with extensive quantitative sampling. *Environ. Monit. Assess.* 99: 99-112. (in English) ["It is a fundamental tenet of Rapid Biological Assessments (RBA) that the samples collected reflect the community from which they are drawn. As with any biological sampling, RBA collections are subject to sampling error resulting in the omission of some taxa. The aim of this study is to compare the composition of RBA samples with an estimate of community structure based on extensive quantitative sampling. We used logistic regression to explore the relationships between the frequency of a taxon being collected in an RBA sample and its biological and ecological traits, namely its abundance, distribution, body size and habit. RBA samples and quantitative estimates of community structure were made in riffles in the Kangaroo and Nepean Rivers, New South Wales, Australia. Single RBA samples may collect up to 63% of the taxa that are collected by extensive quantitative sampling at a site. The frequency of a taxon being recorded in an RBA sample was significantly and positively related to all traits tested indicating a bias in the collection methods towards large, abundant and widely distributed taxa. Accordingly, taxa missed by RBA sampling were generally small, narrowly distributed or rare. These findings enhance our understanding of what RBA samples represent, and the bias and source of errors associated with RBA sampling. This study also quantifies the utility of RBA methods for biodiversity assessment." (Authors) Taxa - including Odonata - are treated at family level.] Address: Hose, G.C., Depart. Biological Sciences, Macquarie University, Sydney, NSW 2109, Australia. E-mail: ghose@els.mq.edu.au

15018. Hassall, C. (2009): Dragonfly and man. *Antenna* 33(2): 98-99. (in English) [Verbatim: It is impossible to ignore the presence of a group of organisms so biologically fascinating and aesthetically striking as the dragonflies and damselflies. This has resulted in their inclusion within the folklore of cultures wherever they occur, although different traditions are divided over whether they represent good or evil. In the East dragonflies are revered as beautiful, noble creatures. So strong is this sentiment that the dragonfly became a national symbol of Japan. After a 7th century Japanese emperor observed a dragonfly killing a gadfly by which he had just been bitten, a haiku was written which renamed

central Japan Akitsu-shima ("Land of the Dragonflies") in honour of the creature. Dragonflies feature widely in eastern medicine, art, poetry (particularly haiku) and even cuisine, where they traditionally feature as a staple part of the Balinese diet when other food sources are rare. The West, on the other hand, has been far more suspicious of the dragonfly. This is immediately evident in some of the colloquial names for the insects: "horse stinger" (UK and Australia), "devil's darned needle" (USA), "troll's spindle" (Sweden) and "eye poker" (Norway). The various legends which give rise to these monikers involve a range of fallacious "old wives tales". The Native Americans are alone among western peoples in considering the dragonfly to be a positive entity, associating it with renewal, swiftness and purity of water. Interestingly, this final belief in the dragonfly as an indicator of water quality has been confirmed and exploited by modern environmental science. Studies of mankind's effects on freshwaters have revealed that the dragonfly and damselflies are particularly sensitive to these impacts, making them ideal "ecological indicators". Indeed, the monitoring of river quality in Europe involves a survey of the invertebrate communities, including a range of dragonfly species, inhabiting those bodies of water in order to make inferences about the state of the river. For all the distrust of dragonflies in the west, there is no doubt that they perform valuable ecological services. Among other tasks in the ecosystem, dragonflies consume vectors of disease, such as mosquitoes, as well as preying on biting and stinging insects, throughout both the aquatic and terrestrial stages of their life cycles. They, in turn, provide a major food source for fish, thus forming a link between the smaller invertebrates in aquatic systems and the larger vertebrate predators. The ancient nature of the order Odonata (which comprises dragonflies and damselflies) is remarkable compared to other orders of animals. The earliest fossil Odonata have been found in sediments from the Lower Permian which date back 250 million years. This is 10-15 million years before the first dinosaur and considerably older than the oldest representative of the primate order (in which *Homo sapiens* is found), which has only recently been pushed back to 85 million years ago. It has been proposed that groups of organisms such as the Odonata that have such extensive and ostensibly stable evolutionary histories should be resilient to modern global change. Evolutionary time can be likened to a hurdles race: the Odonata have persisted through many trials and tribulations, including four major extinction events (one of which claimed the dinosaurs) and countless less severe oscillations of climate and geology. Each of these represents a hurdle over which an organism must leap to survive. However, clearing each hurdle requires certain adaptations and those adaptations will be inherited by successive generations of that species, enabling it to clear similar hurdles in the future. By this reasoning, the modern Odonata should possess a battery of adaptations that leaves them prepared for almost anything Nature could throw at them. Unfortunately it is at this point where the tale becomes less positive for, although the Odonata are extremely flexible in terms of adapting to changes in environmental conditions, there is

evidence that the modern phase of climate change is unprecedented in their evolutionary history. This, therefore, represents a new hurdle which some or all of the Odonata may fail to clear. Added to this is the synergistic impact of other detrimental, anthropogenic factors such as the pollution of water bodies, the draining of marshes and fens and even the well-intentioned (though ultimately destructive) "amelioration" of water bodies through dredging and introduction of damaging plant and fish species. Thus, while humans have a tendency to view dragonflies in a negative light, it is in fact the dragonflies that suffer from their interaction with man. With popular naturalism beginning to show a greater appreciation for the invertebrate world as well as the more traditional cute and cuddly vertebrates, we can only hope that the public will be inspired to help in the conservation of these creatures. For surely there can be few groups of organisms more appropriate as flagship species for the conservation of our wetlands than the dragonflies.] Address: Hassall, C., School of Biology, University of Leeds, Leeds, LS2 3JT, UK. (2009): Aerodynamics of dragonfly flight and robotic design. 2009 IEEE International Conference on Robotics and Automation, Kobe International Conference Center, Kobe, Japan, May 12-17, 2009: 3061-3066. (in English) ["A pair of dynamically scaled robotic dragonfly model wings was developed to investigate the aerodynamic effect of wing-wing interaction in dragonfly flight. Instantaneous aerodynamic forces were measured while forewing-hindwing phase difference (γ) was systematically varied. Experimental results showed that, i) for hovering flight, $\gamma = 0^\circ$ enhanced the lift force on both forewing and hindwing; $\gamma = 180^\circ$ reduced the total lift force, but was beneficial for vibration suppression and body posture stabilization. In nature, 0° is employed by dragonflies in acceleration mode while 180° is usually in hovering mode. ii) For forward flight, wing-wing interaction enhances forewing lift while reduced hindwing lift at all phase differences. Furthermore, the total lift was slightly reduced for $\gamma = 0^\circ$ to 90° and significantly reduced by 18% when $\gamma = 270^\circ$. The results consist well with the fact that, dragonflies usually employ 50° to 100° for forward flight, but seldom employ 270° . PIV results are shown for wing-wing interaction analysis." 15025. Dolný, A.; Mižicová, H. (2010): Habitat requirements and significance of artificial habitats of critically endangered dragonfly *Sympetrum depressiusculum*. *Cas. Sleš. Muz. Opava (A)*, 59: 113-119. (in English, with Czech summary) ["*S. depressiusculum* is currently endangered throughout Europe. This dragonfly, originally from central Siberia, inhabits a close range of natural habitats in Europe, which is even more reduced by inappropriate interventions into the hydrological regime of rivers and lakes. As a result of the anthropogenic changes in aquatic habitats, the species abandons quickly and irreversibly its natural habitats, especially alluvial areas of lakes and unregulated rivers. Recently, however, the species has appeared in artificial habitats, where under suitable conditions numerous populations can be formed. One of the most significant alternative habitats for *S. depressiusculum* are fish breeding ponds. These ponds obviously meet the habitat requirements of the species, because several cases of occurrence have been recorded in these artificial habitats in Central Europe. This paper is primarily focused on the occurrence of the species in fish breeding ponds in the North Moravia region in the Czech Republic. It analyses the factors that influence the occurrence of the species in artificial habitats (fish breeding ponds) in relation to its habitat requirements." Located in a karst terrain in the outer part of the southeastern Dinaric Alps, Lake Skadar is the largest of the Balkan lakes. 49 odonate species are listed.] Address: Gligorovic, B., Department of Biology, Faculty of Sciences, University of Montenegro, Cetinjski put b.b., 81000 Podgorica, Montenegro, E-mail: bogic1@cg.yu

15027. González-Santoyo, I.; Córdoba-Aguilar, A.; González-Tokman, D.M.; Lanz-Mendoza, H. (2010): Phenoloxidase activity and melanization do not always covary with sexual trait expression in *Hetaerina* damselflies (Insecta: Calopterygidae). *Behaviour* 147: 1285-1307. (in English) ["Sexual selection theory indicates that males use sexual traits to signal immune ability, a hypothesis known as the immunocompetence principle. A positive relationship between sexual traits and immune ability is not always present. Here we illustrate this pattern by using five damselfly

species in the genus *Hetaerina*. Previous studies have documented a positive correlation between sexual trait expression (wing spot size) and immune ability in members of this genus. These studies have also documented that there are fitness and energetic costs of producing and bearing wing pigmentation. First we used five *Hetaerina* species to investigate the correlation between spot size and phenoloxidase (PO) activity (a key insect immune component) in two contrasting seasons. Second, we experimentally challenged males of two *Hetaerina* species and correlated spot size with PO activity and melanization ability. Results indicate either a positive relationship, a negative relationship or, more commonly, no relationship at all between immune components and wing pigmentation. Season did not predict any of these relationships or expression of spot size and PO activity. These results, although limited to two immune components, indicate that the relationship between sexual trait expression and immunity is not always consistent." (Authors)] Address: Córdoba-Aguilar, A., Depto de Ecología Evolutiva, Instituto de Ecología, Univ. Nacional Autónoma de México, Apdo. Postal 70-275, Ciudad Universitaria, 04510, México, D. 15028. Iserbyt, A.; Bots, J.; Van Gossum, H.; Jordaens, K. (2010): Did historical events shape current geographic variation in morph frequencies of a polymorphic damselfly? *Journal of Zoology* 282: 256-265. (in English) ["In several animal species, discrete, heritable phenotypic morphs occur in one sex only. This phenomenon is commonly observed in damselfly species where the coexistence of different female colour morphs is often explained in the context of sexual conflict. However, theories based on sexual conflict alone appear to be insufficient for explaining the inter-population variation in morph frequencies. A case in point is the widespread North American damselfly *Nehalennia irene*, in which one female morph occurs predominantly in populations in Western Canada, while another morph is more common in Eastern Canada. Given its large distribution range, historical events may be of particular relevance in explaining the observed spatial variation in morph frequencies in this species. In order to relate the distribution of female morph frequencies with the population genetic structure, we studied sequence variation in five mtDNA gene fragments. Moreover, we compared the population genetic structure of *N. irene* with its sister species *Nehalennia gracilis*, which lacks female polymorphism. Remarkably, our results indicate that the overall genetic variability is three times lower in *N. irene* than in *N. gracilis*, which might be related to the availability of the species' preferred habitat. Furthermore, haplotype and nucleotide diversity of *N. irene* differed considerably among sampled sites and appears to be related to the spatial distribution in female morph frequencies. In addition to previously studied selective agents, we suggest that the species' evolutionary history, such as random genetic drift during recolonization, may also be important in explaining the current geographical distribution of female morph frequencies." 15030. Stauer, M. (2010): Die Verbreitung der Asiatischen Keiljungfer (*Gomphus flavipes*) an Thaya und March. Endbericht. Im Auftrag des WWF Österreich Wien, November 2010: 21 pp. (in German, with English summary) ["The occurrence of the River Clubtail (*Gomphus flavipes*) at the Morava and Dyje — *G. flavipes* is Europe-wide endangered and in Austria critically endangered. It occurs in Austria mainly in the floodplains of Morava and Dyje. Within this research the occurrence of *G. flavipes* at these two lowland rivers along the Austrian-Czech-Slovakian border area was investigated. Main emphasis was to provide evidence of breeding and to assess conservation status of the population on the basis of exuviae. The species is indigenous at the entire section of the Dyje from km 15-0 and at the Morava from km 69-12. Highest amounts of emergences were found at the upper Morava (Hohenau to Sierndorf). This part of population has an excellent conservation status. Part populations at the middle Morava (Jedenspeigen to Zwerndorf) are in good and the ones of Dyje and lower Morava (Zwerndorf to Marchegg) in moderate to poor condition. Additionally exuviae of *Ophiogomphus cecilia* and *G. vulgatissimus* were registered. The conservation status of *O. cecilia*, which is listed in Annex II and IV of the Habitats Directive, was found to be good at the Dyje, the upper and the middle part of the Morava but only moderate to bad at the lower Morava. Within this study there are no evidences from km 17 downstream. Only few *G. vulgatissimus* were recorded, due to the earlier emergence and main flight period of this species." (Authors) (https://www.bmlfuw.gv.at/dam/jcr:f0a2bf7f-979b-4d62-b317-161d774515ed/Keiljungfer_Endbericht.pdf)] Address: Stauer, Martina, Dept für Biodiversität der Tiere, Fakultät für Lebenswissenschaften, Univ. 15031. Strobbe, F.; McPeck, M.A.; De Block, M.; Stoks, R. (2010): Survival selection imposed by predation on a physiological trait underlying escape speed. *Functional Ecology* 24: 1306-1312. (in English) ["(1.) In contrast to other phenotypic traits, selection on physiological traits remains largely undocumented. We have evaluated survival selection imposed by predation by dragonflies on the activity of arginine kinase (Ak), a key enzyme delivering energy for escape performance in invertebrates. (2.) To accomplish this, we conducted a semi-natural field enclosure experiment in which we manipulated predation by large dragonfly predators, and quantified escape swimming speed and Ak in the prey, the damselfly *Enallagma vesperum*. To avoid confounding selection on Ak with selection on other swimming speed-related variables, we also scored all morphological and behavioural traits thought to underlie swimming speed in these

damselflies. (3.) Dragonfly predators imposed considerable mortality and selected for faster swimming speed and higher activity levels of Ak. Furthermore, higher Ak levels contributed to higher swimming speeds, confirming the mechanistic role of Ak for escape performance. Although morphological (size of the caudal lamellae which generate thrust) and behavioural (number of beats made by the abdomen during swimming and the start angle of the C-start) variables contribute to increasing swimming speed, we detected no selection on these variables. This may be due to functional redundancy. (4.) Taken together, our results indicated selection on Ak and suggested that selection on physiological traits may be as strong as selection on morphology and life history traits." 15032. Kato, K.; Watanabe, M. (2011): Foraging flights of *Sympetrum infuscatum* (Selys) adults inhabiting cedar forest gaps of Satoyama (Odonata: Libellulidae). *Japanese journal of entomology* N.S. 14(3): 177-186. (in Japanese) ["After emergence, adults of *S. infuscatum* moves from rice paddy fields to cedar forests of Satoyama in Japan. They stay in the forest gaps throughout their lives, with intermittent visits to rice paddy fields to oviposit there. The forest gaps are used not for mating but for foraging, resting and roosting. They adopt sit-and-wait tactics for foraging to flying small insects such as Diptera and Hymenoptera. The foraging flights of sexually mature adults were observed from late August to early September. The height of perching site was about 2 m in the forest gaps. Each observation was continued until the adult dragonfly left the gap. The foraging flight occurred with a diurnal rhythm, peaking around noon. Females showed 36 foraging flights on average per hour, while males 24 per hour. The number of daily foraging flights was significantly higher in females than in males. About 34% and 33% of flights in females and males, respectively, were successful to capture the target prey. The daily number of captured prey insects was 102 per female and 64 per male. Since the average dry weight of a prey insect flying in forest gaps was 0.17 mg, the daily food intake of a female and a male was calculated 17 mg and 11 mg, respectively, both of which were similar to the amount of food intake estimated in laboratory-reared adults." 15034. Olcott (2011): Final report for the the West Virginia dragonfly and damselfly atlas. Prepared for: West Virginia Division of Natural Resources, Wildlife Resources Section 324 Forth Avenue, South Charleston, WV 25303: 29 pp + 3 app.. (in English) ["The Atlas was successful in expanding knowledge of odonates in West Virginia. A total of 4628 specimens were collected that included representatives from all families known to occur in the state. Five state records and 655 county records were documented. Distribution for most species was expanded, some quite significantly. All 55 of West Virginia's counties were surveyed, with an average of 12 sites visited in each county. State ranks were revised with 73 species warranting a change in their status based on data collected during the Atlas. Results for species distribution in West Virginia (Appendix 1) are based on 1994 and earlier for historical records and 1995 -2010 for recent records." (Author) For details see: <http://www.wvdnr.gov/publications/PDFFiles/OdonateAtlasReportweb.pdf>] Address: Olcott, Susan, West Virginia Division of Natural Resources, Wildlife Resources Section, District 1, 1110 Railroad Street, PO Box 99, Farmington, WV 26571, USA

15037. Alberts, J.M. (2012): Aquatic-to-terrestrial contaminant flux in the Scioto River basin, Ohio, USA. Master of Science in the Graduate School of The Ohio State University: 155 pp. (in English) ["Aquatic emergent insects provide important prey subsidies to riparian consumers. These aquatic-to-terrestrial feeding relationships provide a pathway through which aquatic contaminants are "reterrestrialized" into riparian food webs. However, influences of land use and land cover (LULC) on the magnitude of aquatic-to-terrestrial contaminant transfers remain largely unexplored. To that end, I investigated aquatic-to-terrestrial contaminant fluxes at 11 study reaches in the Olentangy and Scioto Rivers (OH, USA), representing urban, agricultural, and mixed land uses. At nine study reaches, I collected benthic sediment, aquatic emergent insects (including Coenagrionidae and Aeshnidae), ants (*Formica subsericea*), spiders of the family Tetragnathidae, riparian vegetation, and periphyton. At eight of these reaches, as well as additional four reaches where I erected nest-boxes, I sampled riparian swallows including: bank (*Riparia riparia*), northern rough-winged (*Stelgidopteryx serripennis*), tree (*Tachycineta bicolor*), and cliff (*Petrochelidon pyrrhonota*) swallows. Subsequently, all biological samples were analyzed for $\delta^{13}\text{C}$ and $\delta^{15}\text{N}$. Sediment, ants, spiders, and swallows were tested for a suite of toxic elements including arsenic (As), selenium (Se), lead (Pb), and mercury (Hg). Two-source ($\delta^{13}\text{C}$ and $\delta^{15}\text{N}$) mixing models indicated that Tetragnathidae were highly reliant on aquatic insects ($x = 76.9\%$, $SD = 8.9\%$), whereas ant dependence was less but with greater variability ($x = 27.8\%$, $SD = 25.1\%$). Characteristics of shoreline habitat including standing dead trees and % overhanging vegetation explained 70 and 42% of the variation in the contribution of aquatic prey to *F. subsericea* and Tetragnathidae, respectively. Spider density was positively related to land-cover characteristics associated with urbanization (% impervious

surfaces, % invasive shrubs, population density) and near-shore habitat. Shoreline habitat also was strongly related to the overall flux (i.e., contaminant load assimilated into consumer tissue) of Se ($R^2 = 0.58$) and As ($R^2 = 0.51$) to the tetragnathid spider assemblage, and Pb flux to spiders was higher in urban and agricultural reaches than in mixed reaches ($F = 6.10$, $P = 0.025$). *F. subsericea* density exhibited a positive relationship with urbanization ($R^2 = 0.83$). As and Se flux to *F. subsericea* assemblages was positively related to urbanization ($R^2 = 0.70$) as well as shoreline habitat, and Pb flux was higher in urban reaches than other land use types ($F = 8.68$, $P = 0.017$). For swallows, Hg concentrations were significantly higher at rural reaches than at urban reaches ($t = -2.96$, $P = 0.003$, $df = 24$), and Hg concentrations in swallows were positively related to Hg concentrations in sediment ($R^2 = 0.23$, $P = 0.030$), though no relationships were evident for Se in swallows. We found that swallow Hg concentrations were significantly higher in rural than urban reaches ($t = -2.96$, $P = 0.003$, $df = 24$), and marginally so for Se ($t = -1.54$, $P = 0.068$, $df = 24$). To an extent, these relationships appear to be mediated by swallow reliance on aquatic emergent insect prey. For example, swallows that exhibited a higher proportion of aquatic prey in their diet and fed at a higher trophic level also exhibited elevated Se levels. I also found that both Se and Hg concentrations in adult swallows were significantly higher than those observed in juveniles (Se: $t = -3.47$, $P = 0.013$, $df = 4$; Hg: $t = -4.35$, $P = 0.006$, $df = 4$). Collectively, my results indicate that LULC mediates aquatic contaminant flux to terrestrial consumers via regulation of aquatic resource utilization. For riparian arthropods, differences in density associated with landscape variability can result in a significant discrepancy between the magnitude of contaminant export by aquatic emergent insects and the realized contaminant flux to riparian food webs. At a broader spatial scale, riparian swallows may represent a useful assessment tool for contaminant exposure in linked aquatic-terrestrial systems." 15038. Almeida, D.; Almodovar, A.; Nicola, G.G.; Elvira, B.; Grossman, G.D. (2012): Trophic plasticity of invasive juvenile largemouth bass *Micropterus salmoides* in Iberian streams. *Fisheries Research* 113: 153-158. (in English) ["Biological invasions are a major factor for biodiversity loss, particularly in freshwater environments. Largemouth bass *Micropterus salmoides* is native to North America and is invasive on the Iberian Peninsula, primarily to provide angling opportunities in reservoirs. However, this species is a threat to the endemic Iberian fauna via predation and competition. Currently, there is little information on largemouth bass in European streams. Thus, we assessed the trophic plasticity and body condition of young largemouth bass in both invasive (the regulated Bullaque River) and native (Murray Creek) streams. Abundance of juvenile largemouth bass, percentage of full stomachs and body condition were higher in Bullaque River. Largemouth bass preyed on benthic invertebrates much more heavily in the Bullaque River, whereas

fishes were the most important prey in Murray Creek. Prey richness, diet diversity and trophic niche breadth were higher in the Bullaque River population. Largemouth bass preferred water-column fishes as prey and avoided consuming benthic fishes in Murray Creek, whereas water-column fishes were avoided in Bullaque River. These results demonstrate that largemouth bass display substantial trophic plasticity which possibly facilitates its success as invasive species. Regulated Iberian streams may provide both suitable food and habitat resources with minimal predation pressure, and hence may serve as recruitment sources for this invasive fish." (Authors) In Bullaque river, Odonata nymphs are the most important diet of *M. salmoides*.] Address: Almeida, D., Dept Zoology & Physical Anthropology, Complutense University of Madrid, E-28040 Madrid, Spain. 15039. Bell, H.J.; Syed, N.I. (2012): Control of breathing in invertebrate model systems. *Comprehensive Physiology* 2: 1745-1766. (in English) ["The invertebrates have adopted a myriad of breathing strategies to facilitate the extraction of adequate quantities of oxygen from their surrounding environments. Their respiratory structures can take a wide variety of forms, including integumentary surfaces, lungs, gills, tracheal systems, and even parallel combinations of these same gas exchange structures. Like their vertebrate counterparts, the invertebrates have evolved elaborate control strategies to regulate their breathing activity. Our goal in this article is to present the reader with a description of what is known regarding the control of breathing in some of the specific invertebrate species that have been used as model systems to study different mechanistic aspects of the control of breathing. We will examine how several species have been used to study fundamental principles of respiratory rhythm generation, central and peripheral chemosensory modulation of breathing, and plasticity in the control of breathing. We will also present the reader with an overview of some of the behavioural and neuronal adaptability that has been extensively documented in these animals. By presenting explicit invertebrate species as model organisms, we will illustrate mechanistic principles that form the neuronal foundation of respiratory control, and moreover appear likely to be conserved across not only invertebrates, but vertebrate species as well. The central origin of breathing rhythm has been studied in a variety of insect species including ... dragonflies such as *Anax imperator*." 15044. Kiany, M.; Sadeghi, S. (2012): Destroy and pollution of environment of Nahr-e Azam river in Shiraz and endangered Odonata. Abstracts of the 17th National & 5th International Iranian Biology Conference: (in English) [Verbatim: Nahr-e Azam river is one of the most important aquatic ecosystems and water sources of Shiraz using for irrigation of main part of gardens. Main source of this permanent small river is Jooshak spring which its natural and beautiful ecosystem is destroying to make an artificial promenade. Passage of river water had changed and water of spring polluted in short distance with sewage of Ghasre-Ghomshah town. In addition, along the river various pollutants such as sewage, industrial chemicals and polymer wastes

enter to the river water body. Odonata are one of important inhabitant insects in this area that are very sensitive to the polluted environment. Predatory and biological control role of this group on population of other unfavourable insects is especially important. Faunistic studies of this area from five years ago up to now shows richness of Odonata fauna in this environment with around 22 species (about a quarter of total number of odonates of Iran). On the other hand, we found that sudden disappearance of some species in recent years is due to increasing pollution and destroying. If these ruinous actions continue as before, we will lose noteworthy valuable species of this region that some recorded in IUCN red list as endangered species.] Address: Kiany, M., Biol. Dept, Shiraz Univ., Shiraz, Iran. E-mail: mohsen.kiany1@gmail.com

15045. Kiany, M.; Sadeghi, S. (2012): A preliminary study on Odonata fauna of Yazd province. Abstracts of the 17th National & 5th International Iranian Biology Conference: (in English) [Verbatim: Although Yazd province has located in central desert of Iran with arid climate, it contains some specific species of Odonata. In this primary study we surveyed, for the first time, Yazd, Mehriz and Taft regions in Yazd province (Iran) to measure Odonata fauna of central desert of Iran. Eight species, from four different families were recorded from this province. One of the species is new for Iranian fauna and is reported for the first time (shown with asterisk below). Freshwater sources for water-dependent insects in these arid regions are prepared by Karizes and the water almost flows a long distance through concrete canals. Adaptation of species with this condition seems to be really interesting. The specimens consist of: *Platycnemis dealbata*, **Ischnura intermedia*, *Paragomphus lineatus* and *Onychogomphus lefebvrei*, *Crocothemis erythraea*, *Orthetrum chrysostigma* and *Trithemis festiva*.] Address: Kiany, M., Biology Department, Shiraz University, Shiraz, Iran. 15052. Van Schandevyl, D. (2012): Observations of Odonata in a nature reserve along the river Dender (Belgium - East-Flanders) in 1996-2007. *Brachytron* 15(1): 43-52. (in Dutch, with English summary) ["The article gives a summary of dragonfly observations in the Wellemersen, a nature reserve of about 100 hectares situated on the left bank of the river Dender near Denderleeuw, in the province of Eastern Flanders (Belgium). The importance of this site as a 'trap area' for dragonflies was first discovered by H. Dumont who published an extended species list in 1971. The area is delimited by linear elements such as railroads and a motorroad which might serve as artificial pathways for dragonfly distribution. The data were collected in the period 1996-2007 and have been published in a comprehensive report with detailed descriptions of the status, observations and distribution (including maps) of each species. In this article, a short description is given of some specific (but mostly artificial) dragonfly biotopes, like old sandpits, large ponds, former bomb holes, fishing ponds and flooded meadows. Most of the 1840 data records were collected by sight. The area was subdivided into 184 separate inventory units to provide detailed location data. All dubious observations were carefully checked. A total of 34 species were found, of which 23 can be considered as autochthonous. All belong to the Red List category 'Not threatened'. Nine species are dwellers. Distribution and abundance are discussed. More than 55% of the records originate from 6 species: *Ischnura elegans*, *Aeshna cyanea*, *Coenagrion puella*, *Sympetrum sanguineum*, *Anax imperator* and *S. striolatum*. The least abundant are *Aeshna grandis*, *Cordulia aenea*, *Crocothemis erythraea*, *Enallagma cyathigerum*, *Erythromma lindennii* and *Lestes sponsa*. The most widespread species within the study area (in more than 50% of the total of 184 inventory blocks) are *Ischnura elegans* and *S. sanguineum*, followed by *A. cyanea*, *S. striolatum* and *A. mixta*. Within the Flemish context, the Wellemersen can be considered as a fairly rich dragonfly area. A comparison with Dumont's list shows that two species, *Brachytron pratense* and *Aeshna isocetes*, have not been observed again and have most

probably disappeared from the area. On the other hand, new permanent inhabitants are *Erythromma viridulum*, *Crocothemis erythraea* and *Cordulia aenea*. The last two were only occasionally seen during the former period." (Author)] Address: Van Schandevyl, D., Paardekastanje 36, 9470 Denderleeuw, The Netherlands. (2012): The distribution of heavy metals in known and potential Hine's emerald dragonfly (*Somatochlora hineana*) habitat near the Viburnum Trend mining district of southeast Missouri, USA. Prepared by: J.S. Weber, U.S. Department of the Interior, Fish and Wildlife Service, Southeast Missouri Lead Mining District, Natural Resource Damage Assessment and Restoration: 23 pp. (in English) ["The Viburnum Trend mining district in southeast Missouri, USA is one of the largest producers of lead in the world. Previous biological surveys in the district have found evidence demonstrating metal exposure of birds, insects, fish and crayfish. This study examined heavy metal concentrations in the sediment and water of freshwater wetlands known to be or potentially occupied by the federally endangered *Somatochlora hineana*. Sediment samples were collected from thirteen sites to assess the potential exposure of the dragonfly to mining-derived metals. Water samples were also collected at the sampling sites when sufficient surface water was available for collection. Concentrations of metals (lead, zinc, cadmium, nickel, et al.) were analyzed in the surface water and sediment. Mean concentrations of lead in sediments were significantly greater ($P < 0.01$) at sites potentially impacted by mining compared to reference sites. Sediment concentrations of lead exceeded consensus-based threshold effects concentrations at eight of ten sites potentially impacted by mining. Concentrations of dissolved metals in surface water samples did not exceed Aquatic Life Criteria established by the State of Missouri. These findings suggest that metals associated with mining activities in the Viburnum Trend may have the potential to negatively impact *S. hineana* populations in and around the district." 15055. Alberts, J.M.; Sullivan, M.P.; Kautza, A. (2013): Riparian swallows as integrators of landscape change in a multiuse river system: Implications for aquatic-to-terrestrial

transfers of contaminants. *Science of the Total Environment* 463-464: 42-50. (in English) ["Recent research has highlighted the transfer of contaminants from aquatic to terrestrial ecosystems via predation of aquatic emergent insects by riparian consumers. The influence of adjacent land use and land cover (LULC) on aquatic-to-terrestrial contaminant transfer, however, has received limited attention. From 2010 to 2012, at 11 river reaches in the Scioto River basin (OH, USA), we investigated the relationships between LULC and selenium (Se) and mercury (Hg) concentrations in four species of riparian swallows. Hg concentrations in swallows were significantly higher at rural reaches than at urban reaches ($t = -3.58$, $P < 0.001$, $df = 30$), whereas Se concentrations were positively associated with adjacent land cover characterized by mature tree cover ($R^2 = 0.49$, $P = 0.006$). To an extent, these relationships appear to be mediated by swallow reliance on aquatic emergent insects. For example, tree swallows (*Tachycineta bicolor*) at urban reaches exhibited a higher proportion of aquatic prey in their diet, fed at a higher trophic level, and exhibited elevated Se levels. We also found that both Se and Hg concentrations in adult swallows were significantly higher than those observed in nestlings at both urban and rural reaches (Se: $t = -2.83$, $P = 0.033$, $df = 3$; Hg: $t = -3.22$, $P = 0.024$, $df = 3$). Collectively, our results indicate that riparian swallows integrate contaminant exposure in linked aquatic-terrestrial systems and that LULC may strongly regulate aquatic contaminant flux to terrestrial consumers." (Authors) Coenagrionidae made up nearly 30% of all aquatic individuals collected, whereas Aeshnidae represented the largest-bodied prey item.] Address: Alberts, J.M., Dept of Biol.Sci., Univ. 15059. Cordero-Rivera, A. (2013): Demographics and adult activity of *Hemiphysalis mirabilis*: a short-lived species with a huge population size (Odonata: Hemiphysalidae). <http://natureglenelg.org.au/wp-content/uploads/2014/02/Behaviour-and-ecology-of-Hemiphysalis-mirabilis-by-Adolfo-Cordero-Rivera-2014.pdf>: 38 pp. (in English) ["Conclusions: The observations and analyses presented here (which have to be treated as preliminary) indicate that this species has a copulatory behaviour similar to other Zygoptera, and sperm removal is likely to be performed by males. The specimens that were collected and preserved in ethanol, will be dissected in the next months, and hopefully a detailed description of sperm competition will be possible. *H. mirabilis* males perform an elaborated courtship display, which uses in part its well-known flicking behaviour. This was an unexpected result, and suggests that precopulatory sexual selection might be intense in this species. I was able to observe and describe reproductive behaviour (goal 1 of this work), but I could not observe oviposition, neither elicit egg-laying on humid filter paper and plant tissue. Therefore, the second goal of the study, to develop methods for captive breeding, could not be achieved. Nevertheless, I dissected eggs from two mature females and preserved them in a buffer for transmission electron microscopy. Their study will be done during 2014. The dense vegetation of Long Swamp was too thick for behavioural observations. If females lay eggs at the base of the reeds, this is unlikely to be observed. Even mating pairs were very difficult to detect among the vegetation. Furthermore, individuals in copula were never seen flying, which also difficult detection. The fact that no focal female attempted oviposition suggests that this behaviour might take place during the night. Nevertheless, five females were maintained over night with humid filter paper, and did not lay eggs. The structure of the vegetation at Ming Ming Swamp is more favourable for behavioural observations. *H. mirabilis* was very common when I visited the swamp, and I think that detailed observations at that place would be fruitful to detect oviposition. My mark-recapture experiment, with all the limitations inherent to a study made by only one worker, yielded surprisingly high population density estimates, which are concordant with field observations. Davies (1985) estimated a density of 100 animals per 10 m², which is three times my estimates, but at particular times I observed similar densities. The population of *H. mirabilis* at Long Swamp is therefore huge, very likely more than one million specimens per season. Its has also been found in large numbers in several swamps in Grampians National Park (Reiner Ritcher, pers. comm). I therefore agree with the opinion of other researchers, which suggested that this species should no longer be regarded as critically endangered (Trueman et al. 1992; Watson 1995)."]

15060. Cothran, R.D.; Brown, J.M.; Relyea, R.A. (2013): Proximity to agriculture is correlated with pesticide tolerance: evidence for the evolution of amphibian resistance to modern pesticides. *Evolutionary Applications* 6(5): 832-841. (in English) ["Anthropogenic environmental change is a powerful and ubiquitous evolutionary force, so it is critical that we determine the extent to which organisms can evolve in response to anthropogenic environmental change and whether these evolutionary responses have associated costs. This issue is particularly relevant for species of conservation concern including many amphibians, which are experiencing global declines from many causes including widespread exposure to agrochemicals. We used a laboratory toxicity experiment to assess variation in sensitivity to two pesticides among wood frog (*Lithobates sylvaticus*) populations and a mesocosm experiment to ascertain whether resistance to pesticides is associated with decreased performance when animals experience competition and fear of predation. We discovered that wood frog populations closer to agriculture were more resistant to a common insecticide (chlorpyrifos), but not to a common herbicide (Roundup). We also found no evidence that this resistance carried a performance cost when facing competition and the fear of predation. To our knowledge, this is the first study demonstrating that organophosphate insecticide (the most commonly applied class of insecticides in the world) resistance increases with agricultural land use in an amphibian, which is consistent with an evolutionary response to agrochemicals. ... For mesocosms assigned the predator treatment, we added a single larval dragonfly (*Anax junius*) to the predator cage and fed each predator three times a week using approximately 300 mg of wood frog tadpoles from a mixture of the nine populations." 15061. Engel, M.S.; Davis, S.R.; Prokop, J. (2013): Insect wings: The evolutionary development of nature's first flyers. Minelli, A., G. Boxshall & G. Fusco (2013): *Arthropod Biology and Evolution*: 269-298. (in English) ["Powered flight is one of the more spectacular evolutionary novelties to have come about during the 4-billion-year history of life on Earth. Flight bestows upon the flyer another dimension in which to experience life. Suddenly, new avenues are available for dispersal, escape and avoidance, locating a suitable mate, and reaching once unobtainable resources. Moreover, wings can be so much more than merely a means to fly. Properly adapted the wings themselves may play a role in courtship, camouflage and mimicry, thermoregulation, and protection and defence. Despite the profound significance of flight, it is a challenging feat to achieve and control. Powered flight has evolved independently at least four times, three of which occur among the Amniota, while the last is

far flung across the branches of the animal tree of life. It is this last lineage that was also the first to evolve this singularly successful means of locomotion, rivalling in numbers of species all other forms of life combined." (Authors) The paper includes many references to Odonata.] Address: Engel, M.S., Division of Entomology, Natural History Museum, and Department of Ecology and Evolutionary Biology, University of Kansas, 1501 Crestline Drive—Suite 140, Lawrence, Kansas, 66045, USA. 15066. Klecka, J.; Boukal, D.S. (2013): Foraging and vulnerability traits modify predator-prey body mass allometry: freshwater macroinvertebrates as a case study. *Journal of Animal Ecology* 82(5): 1031-1041. (in English) ["Predation is often size selective, but the role of other traits of the prey and predators in their interactions is little known. This hinders our understanding of the causal links between trophic interactions and the structure of animal communities. Better knowledge of trophic traits underlying predator-prey interactions is also needed to improve models attempting to predict food web structure and dynamics from known species traits. We carried out laboratory experiments with common freshwater macroinvertebrate predators (diving beetles, dragonfly and damselfly larvae and water bugs) and their prey to assess how body size and traits related to foraging (microhabitat use, feeding mode and foraging mode) and to prey vulnerability (microhabitat use, activity and escape behaviour) affect predation strength. The underlying predator-prey body mass allometry characterizing mean prey size and total predation pressure was modified by feeding mode of the predators (suctorial or chewing). Suctorial predators fed upon larger prey and had ~3 times higher mass-specific predation rate than chewing predators of the same size and may thus have stronger effect on prey abundance. Strength of individual trophic links, measured as mortality of the focal prey caused by the focal predator, was determined jointly by the predator and prey body mass and their foraging and vulnerability traits. In addition to the feeding mode, interactions between prey escape behaviour (slow or fast), prey

activity (sedentary or active) and predator foraging mode (searching or ambush) strongly affected prey mortality. Searching predators was ineffective in capturing fast-escape prey in comparison with the remaining predator–prey combinations, while ambush predators caused higher mortality than searching predators and the difference was larger in active prey. Our results imply that the inclusion of the commonly available qualitative data on foraging traits of predators and vulnerability traits of prey could substantially increase biological realism of food web descriptions." 15069. Neff, B.D.; Svensson, E.I. (2013): Polyandry and alternative mating tactics. *Phil. Trans. R. Soc. B* 368: 20120045: 11 pp. (in English) ["Many species in the animal kingdom are characterized by alternative mating tactics (AMTs) within a sex. In males, such tactics include mate guarding versus sneaking behaviours, or territorial versus female mimicry. Although AMTs can occur in either sex, they have been most commonly described in males. This sex bias may, in part, reflect the increased opportunity for sexual selection that typically exists in males, which can result in a

higher probability that AMTs evolve in that sex. Consequently, females and polyandry can play a pivotal role in governing the reproductive success associated with male AMTs and in the evolutionary dynamics of the tactics. In this review, we discuss polyandry and the evolution of AMTs. First, we define AMTs and review game theoretical and quantitative genetic approaches used to model their evolution. Second, we review several examples of AMTs, highlighting the roles that genes and environment play in phenotype expression and development of the tactics, as well as empirical approaches to differentiating among the mechanisms. Third, ecological and genetic constraints to the evolution of AMTs are discussed. Fourth, we speculate on why female AMTs are less reported on in the literature than male tactics. Fifth, we examine the effects of AMTs on breeding outcomes and female fitness, and as a source, and possibly also a consequence, of sexual conflict. We conclude by suggesting a new model for the evolution of AMTs that incorporates both environmental and genetic effects, and discuss some future avenues of research." 15075. Riens, J.R.; Schwarz, M.S.; Mustafa, F.; Hoback, W.W. (2013): Aquatic macroinvertebrate communities and water quality at buffered and non-buffered wetland sites on federal waterfowl production areas in the Rainwater Basin, Nebraska. *Wetlands* 33(6): 1025-1036. (in English) ["Nebraska's Rainwater Basin has an abundance of natural wetlands and is a focal point in the annual migration corridor used by millions of waterfowl and shorebirds. However, these wetlands are in a landscape dominated by agriculture and as a result, siltation and poor water quality are continual problems. We evaluated twelve wetland sites on federally managed Waterfowl Protection Areas from 2007 – 2009 for water quality, sediment quality, and macroinvertebrate diversity. Six of the sites received agricultural runoff directly via culverts and drainage ditches (non-buffered sites) and six sites were protected from agricultural runoff by a vegetated buffer (buffered sites). Mean total number of aquatic macroinvertebrates were significantly greater ($p < 0.001$) for buffered sites (230 ± 744 standard error) than non-buffered sites (97 ± 724). Water from non-buffered sites had significantly greater turbidity, conductivity, and concentrations of chlorophyll a and atrazine than buffered sites in addition to consistently greater annual averages of total nitrogen and total phosphorus. Furthermore, sediments from non-buffered sites had significantly greater cadmium, potassium, sodium and zinc than buffered sites. Use of vegetative buffers to intercept direct row-crop runoff can improve water quality and aquatic macroinvertebrate diversity and abundance in Rainwater Basin wetlands." (Authors) Taxa - including Odonata - are treated at the family level.] Address: Riens, J.R., US Fish & Wildlife Service, 1936 California Ave., Klamath Falls, OR, 97601, USA. 15076. Satake, K.; Ueno, R. (2013): Distribution of freshwater macroinvertebrates in streams with dams and associated reservoirs on a subtropical oceanic island off southern Japan. *Limnology* 14(2): 211-221. (in English) ["The conservation of endemic fauna in freshwater ecosystems is a topical issue on small oceanic islands. Because these endemics have limited distributions, they are more vulnerable to extinction. This study is the first to clarify the distribution of freshwater macroinvertebrates including endemic and alien species in streams with dams and associated reservoirs on the Ogasawara Islands in the northwestern Pacific

Ocean. In 2007, we conducted a field survey in streams and reservoirs of the Yatsuse River system and collected 22 taxonomic groups from 13 stations. Hierarchical cluster analysis and non-metric multi-dimensional scaling (NMDS) were performed for the presence/absence data of the macroinvertebrates, and the results indicated that (1) most of endemic species were present in inlet streams of dam reservoirs, (2) these endemic species were absent in the bottom sediments of the reservoirs because of oxygen depletion and (3) dams may be barriers to the migration of some species of amphidromous crustaceans. Because human modifications, such as dams and associated reservoirs, on a small oceanic island can rapidly result in fragmentation or loss of freshwater habitats of endemic species, the remaining habitat of these species, such as headwater streams, must be protected and preserved to avoid species extinction." (Authors) The list of taxa includes *Pantala flavescens* and *Ischnura senegalensis*, sampled in the littoral zone of Station 8 and 11.]Address: Satake, K., National Institute for Environmental Studies, 16-2 Onogawa, Tsukuba, Ibaraki, 305-8506, Japan. 15077. Sharma, A.K.; Bisen, U.K. (2013): Taxonomic documentation of insect pest fauna of vegetable ecosystem collected in light trap. *International Journal of Environmental Science: Development and Monitoring* 4(3): 4-11. (in English) ["The present study was conducted under the study of scope of light trap as IPM technology in Vegetable ecosystem. Information on insect pest fauna of vegetable ecosystem collected in Balaghat region of M.P. The data of trap catch during the year 2006 (Kharif season) was classified on taxonomic basis, economic aspect (crop pest) and bio control significance (parasite and predators) a total of 56 species were recorded in Kharif cropping season of vegetable cropping area. These insect pest belongs to 8 orders and 34 families .Lepidoptera was the largest order with 23 species .Other orders were Hemiptera (14species), Coleoptera (11 species) and Orthoptera (4 species). Odonata, Hymenoptera, Isopteran and Dictioptera were the other order of minor significance. Based on economic importance this collection was represented by 39 species of harmful insects (as crop pest) 17 species of predatory insects (useful as bio-control agents). Category of harmful insect pests includes the major and minor pest species of vegetables, major polyphagous pests, pests of Paddy, Pulses, Cereals, Oilseeds and other crops .The present study reviles that documented information on these species gives broader scope of using light trap as Integrated Pest Management tool against these insect pests of vegetables and other crops. The trap catch data also provide voluble information on bio control agents (predatory) active in vegetable ecosystem." 15078. Sharma, G. (2013): Faunal exploration of Kumbhalgarh Wildlife Sanctuary, Rajasthan. 3. Insecta: Odonata. *Conservation Area Series* 47: 31-42. (in English) [A total of 17 species belonging to 13 genera under 4 families and 2 suborders of order Odonata are first time reported from

Kumbhalgarh Wildlife Sanctuary, Rajasthan, India.] Address: Sharma, G., Desert Regional Centre, Zoological Survey of India, Jodhpur, India

15079. Stevove, B.; Kovac, V. (2013): Do invasive bighead goby *Neogobius kessleri* and round goby *N. melanostomus* (Teleostei, Gobiidae) compete for food? *Knowledge and Management of Aquatic Ecosystems* (2013) 410, 08: 15 pp. (in English, with French summary) ["Bighead goby (*Neogobius kessleri*) and round goby (*Neogobius melanostomus*) have been invading new non-native areas about two decades successfully. In this study, diet spectrum, seasonal variation, feeding strategy and diet overlap between these two invasive species were assessed. Materials were collected from the Danube at Bratislava by fishing rods and/or electrofishing. The diet spectrum of both species was diverse: a total of 46 food types in bighead goby and 51 food types in round goby were observed. *Dikerogammarus* sp., chironomid larvae and *Corophium* sp. were the most predominant food types in bighead goby, whereas in round goby, chironomid larvae, *Corophium* sp., bryozoans and Cladocera predominated. The diet varied over seasons. In the Slovak part of the Danube, bighead goby and round goby have adapted to local food resources, consuming diverse food from small to large items, both with soft and/or hard body. This enhances the capability of these invasive species to spread successfully. It appears that even if both exploit similar food resources, their proportional content differs. Further differences between these gobies were also found in their food behaviour and feeding strategy. Both species tend to be specialists where possible, but round goby demonstrates higher flexibility towards general feeding strategy." (Authors) In case of *N. kessleri*, a few Coenagrionidae and Gomphidae contributed to diet, in case of *N. melanostomus* no Odonata were found as diet.] Address: Števo, B., Department of Ecology, Faculty of Natural Sciences, Comenius University, Mlynská dolina, 842 15 Bratislava, Slovakia. 15080. Tanneberger, F.; Bellebaum, J.; Helmecke, A.; Minets, M. (2013): Nesting and foraging characteristics of Aquatic Warblers *Acrocephalus paludicola* in the fast declining Pomeranian population (NE Germany/ NW Poland). *Acta Ornithologica* 48(1): 109-118. (in English) ["Limited food availability could be a cause for the strong decline of the small and isolated Aquatic Warbler population in Pomerania (NE Germany/NW Poland). In this paper, we describe nesting site conditions, nest placement and female foraging behaviour as well as food supply in vegetation types prevailing in Pomeranian breeding areas. Female Aquatic Warblers in Pomerania appeared to select 'managed' sites (where land use maintains suitable conditions for Aquatic Warbler) for nesting, and preferred vertical structures (ditches and edges within 'managed' sites) for foraging. They flew longer distances for provisioning their nestlings than in the core population (E Poland, Belarus) whereas the total distance travelled per 30 minutes was similar. In 'managed' sites, the total invertebrate biomass was larger than in 'unmanaged' sites in early June when

early broods are raised. Pomeranian Aquatic Warblers are able to exploit relatively rich food sources in 'managed' meadows and in vertical structures and may thus balance the higher efforts of flights longer than in Eastern Poland and Belarus. To increase the availability of suitable Aquatic Warbler nesting and foraging sites in Pomerania, management by mowing should be continued. It might yield the best results when providing a mosaic of 'managed' and 'unmanaged' patches." (Authors) No taxonomic details on the diet of *A. paludicola* is given. Biomass of food resources is calculated in the case of Odonata as follows: mean Zygoptera fresh weight 11 mg; mean Anisoptera fresh weight 56 mg.] Address: Tanneberger, Franziska, Institute of Botany & Landscape Ecology, Greifswald Univ., Grimmer Str. 88, 17489 Greifswald, Germany. 15081. van Strien, A.J.; van Swaay, C.A.M.; Termaat, T. (2013): Opportunistic citizen science data of animal species produce reliable estimates of distribution trends if analysed with occupancy models. *Journal of Applied Ecology* 50(6): 1450-1458. (in English) ["(1.) Many publications documenting large-scale trends in the distribution of species make use of opportunistic citizen data, i.e. observations of species collected without standardized field protocol and without explicit sampling design. It is a challenge to achieve reliable estimates of distribution trends from them, because opportunistic citizen science data may suffer from changes in field efforts over time (observation bias), from incomplete and selective recording by observers (reporting bias) and from geographical bias. These, in addition to detection bias, may lead to spurious trends. (2.) We investigated whether occupancy models can correct for the observation, reporting and detection biases in opportunistic data. Occupancy models use detection/non-detection data and yield estimates of the percentage of occupied sites (occupancy) per year. These models take the imperfect detection of species into account. By correcting for detection bias, they may simultaneously correct for observation and reporting bias as well. We compared trends in occupancy (or distribution) of butterfly and dragonfly species derived from opportunistic data with those derived from standardized monitoring data. All data came from the same grid squares and years, in order to avoid any geographical bias in this comparison. (3.) Distribution trends in opportunistic and monitoring data were well-matched. Strong trends observed in monitoring data were rarely missed in opportunistic data. (4.) Synthesis and applications. Opportunistic data can be used for monitoring purposes if occupancy models are used for analysis. Occupancy models are able to control for the common biases encountered with opportunistic data, enabling species trends to be monitored for species groups and regions where it is not feasible to collect standardized data on a large-scale. Opportunistic data may thus become an important source of information to track distribution trends in many groups of species." (Authors) The study bases on the data of National Database Flora and Fauna and Dutch Dragonfly and Butterfly Monitoring Schemes.] Address: van Strien, A.J., Statistics Netherlands, P.O. 15082. Vittoz, P.; Cherix, D.; Gonseth, Y.; Lubini, V.; Maggini, R.; Zbinden, N.; Zumbach, S. (2013): Climate change impacts on biodiversity in Switzerland: A review. *Journal for Nature Conservation* 21(3): 154-162. (in English) ["A noticeable increase in mean temperature has already been observed in Switzerland and summer temperatures up to 4.8 K warmer are expected by 2090. This article reviews the observed impacts of climate change on biodiversity and considers some perspectives for the future at the national level. The following impacts are already evident for all considered taxonomic groups: elevation shifts of distribution towards mountain summits, spread of thermophilous species, colonisation by new species from warmer areas and phenological shifts. Additionally, in the driest areas, increasing droughts are affecting tree survival and fish species are suffering from warm temperatures in lowland regions. These observations are coherent with model projections, and future changes will probably follow the current trends. These changes will likely cause extinctions for alpine species (competition, loss of habitat) and lowland species (temperature or drought stress). In the very urbanised Swiss landscape, the high fragmentation of the natural ecosystems will hinder the dispersal of many species towards mountains. Moreover, disruptions in species interactions caused by individual migration rates or phenological shifts are likely to have consequences for biodiversity. Conversely, the inertia of the ecosystems (species longevity, restricted dispersal) and the local persistence of populations will probably result in lower extinction rates than expected with some models, at least in 21st century. It is thus very difficult to estimate the impact of climate change in terms of species extinctions. A greater recognition by society of the intrinsic value of biodiversity and of its importance for our existence will be essential to put in place effective mitigation measures and to safeguard a maximum number of native species." (Authors) The paper includes a discussion section with Odonata.] Address: Vittoz, P., Dept of Ecology & Evolution, Univ. of Lausanne, Bâtiment Biophore, 1015 Lausanne, Switzerland

15083. Wezel, A.; Chazoule, C.; Vallod, D. (2013): Using biodiversity to valorise local food products: the case of fish ponds in a cultural landscape, their biodiversity, and carp production. *Aquaculture International* 21(6): 1395-1408. (in English) ["Today, we need to produce sufficient food and simultaneously conserve biodiversity. But, could biodiversity associated with certain food production practices also be used in marketing products? We analyse this possibility for creating a food quality label for carp raised in the Dombes territory, a cultural landscape of fish ponds in France. The biodiversity of 99 fish ponds was studied in the Dombes territory by analysing aquatic vegetation, dragonflies, amphibians, macroinvertebrates, habitats around ponds, and water quality. In addition, a survey with 200 questionnaires and interviews was conducted with consumers to investigate fish and carp consumption and knowledge about quality labels and biodiversity. Findings reveal that fish production practices conserve remarkable species diversity, particularly for aquatic vegetation, dragonflies and amphibians, and habi-

tats around the ponds. This relatively high level of biodiversity is found in spite of having very nutrient-rich fish pond systems, systems for which normally a low level of biodiversity is expected. Nevertheless, currently this biodiversity cannot be valorised for setting up a quality label for locally produced carp. Firstly, few consumers have adequate knowledge about carp and are interested in eating it. Secondly, most of them have less knowledge about the quality label which wanted to be established for carp from the Dombes. Thirdly, only less than one-third of the consumer is familiar with the term "biodiversity". Fourthly, the stakeholder network of the supply chain is presently not able to communicate the message of biodiversity as they themselves lack a sufficient knowledge about biodiversity of their systems. ... In total, 31 dragonfly species were observed. The mean per pond was 13 and a range from 6 to 22. Two endangered dragonfly species were observed, *Leucorrhinia pectoralis* (EU Habitat Directive and French red list of threatened species) and *Aeshna isocetes* (French red list of endangered species) (Leclerc et al. 2010). Compared with other wetland areas, for example, the Saone floodplain (Oertli 1995) or the ponds from Switzerland (Oertli et al. 2002), the species richness of the Dombes ponds is high and benefits most likely from the dense network of ponds." (2013): Effects of grass seed agriculture on aquatic invertebrate communities inhabiting seasonal wetlands of the southern Willamette Valley, Oregon. *Wetlands* 33(5): 921-937. (in English) ["Wetland loss throughout the United States has contributed substantially to landscape fragmentation and loss in biodiversity. In Oregon's Willamette Valley, only 1 % of native-wet prairie habitat still exists, though seasonal wetlands are still common. These hydrogeomorphic Flats wetlands predominately occur on privately owned and actively farmed lands. We studied these wetlands in spring of 2009 and 2010 in order to quantify and compare aquatic invertebrate communities in two agricultural land-use groups (annual and perennial-grass-seed fields) with native-wet prairie habitat. Community composition in native-prairie, including higher taxa richness and greater diversity, differed from farmed wetlands. Invertebrate densities did not differ among land-uses. However, biomass in perennial-grass wetlands was greater than in annual-grass wetlands both years, and during 2009, it was more than in native-prairie. Lower turbidity, lower conductivity levels, and greater availability of rooted vegetation in native-prairie habitat were conditions associated with differences in invertebrate composition among land-uses. Though invertebrate communities in farmed wetlands differed from native-prairie, the importance of these seasonal wetlands in an altered and fragmented Willamette Valley landscape speaks to their potential contribution for the region's biodiversity and to their inclusion for management of agricultural lands." 15086. Almeida, M.C. (2014): Diversity and vulnerability of aquatic insects in productive landscapes. Tese (Doutorado) – Programa de Pós-Graduação em Ciências Ambientais, Universidade Federal de Goiás, Goiânia: 156 pp. (in Portuguese, with English summary) ["Loss and habitat fragmentation at the landscape scale, the land use and local integrity of habitats (e.g. riparian forests), associated with the social structure of rural lands are factors that can determine the loss of species. These could be greater where of landscapes is homogenized by the same type of land use, such as in agricultural areas. This has important consequences and could be determine that Conservation Biology practices are not based only on Protected Areas. These approaches applied to aquatic insects occurring in Cerrado of Goiás state show that endangered species of Odonata, distributed in the central and south region presented a historical habitat loss of 76%. Regional assessment according to the criteria of the IUCN, a total of 34.8% of species would be in some category of threat, these 71.5% were Critically Endangered, 22,8% Endangered and 4.9% would be vulnerable. Local environmental variables, spatial structure of habitat and matrix in buffers of 250 meters and habitat spatial structure and matrix in the landscapes of 25 by 25 km explained the local richness of Odonata adults in streams. Richness decreases with increase in pasture in the 250 meters buffers and crop in the landscape and increases with the opening canopy. For Ephemeroptera, Plecoptera and Trichoptera (EPT) immature, richness increases with increasing riparian forest

250 meters buffers, with the opening of canopy and the average conductivity of the water. When we consider the habitat integrity (riparian) associated with the structure of rural property around protected areas, the integrity of riparian vegetation as measured by NDVI was lower in the Buffer Zone of sustainable protect areas associated with small farms. The area of the property dedicated to the cultivation and cattle size has direct impacts to lower NDVI values." (Author)] Address: not stated

15087. Andersson, J. (2014): Aquatic insect community structure in urban ponds: effects of environmental variables. M.Sc. thesis, Biology Education Centre and Department of Ecology and Genetics, Uppsala University: 42 pp. (in English) ["I sampled aquatic insects in 26 ponds of varying types in the urban landscape of the city of Stockholm and related insect community structure to environmental variables. I also related environmental factors to species richness, diversity and abundance of the sampled aquatic insects. A Redundancy Analysis (RDA) showed that the most important variables in explaining insect community structure was the remoteness to developed area and the amount of emergent vegetation in the ponds. Species richness increased with distance from developed area, diversity was related to floating vegetation and abundance of insects increased with distance from developed area and with higher amount of forestation and vegetation. The results of my study shows that urbanization effects divide the insect community into clusters of species that are tolerant or intolerant to effects of urbanisation. *Leucorrhinia pectoralis* was found in five (19,2%) of the ponds. My result suggested two important factors that should be considered when planning urban ponds. First, it is important to re-create varying types of ponds and include green buffer areas and second, plant colonisation should be facilitated to better mimic the natural states of ponds." (in English) ["The objectives of the present study were to explore the Diversity and abundance of Odonata of Ankalga vilage, near back waters of benethora reservoir, Gulbarga District, Karnataka. Odonata fauna of present study was investigated in monsoon season from July 2013 to October 2013, total 14 species belonging to four families of dragonflies and damselflies were recorded, in which the most abundant family was Libellulidae followed by Coenagrionidae, Gomphidae and Platycnemididae. Libellulidae family represents 10 species, Coenagrionidae represents 2 species, Gomphidae represents 1 species, while Platycnemididae also represents with 1 species. We also calculated the Species diversity (H) and Evenes (E) which is 2.371 and 0.901 respectively. From above study we conclude that he present study area is rich in Odonata fauna in monsoon

season." (Authors)] Address: Ankalgi, Sulochana, Dept of Zoology Gulbarga University, Gulbarga, Karnataka, India

15089. Batabyal, A.; Gosavi, S.M.; Gramapurohit, N.P. (2014): Determining sensitive stages for learning to detect predators in larval bronzed frogs: Importance of alarm cues in learning. *Journal of Biosciences* 39(4): 701-710. (in English) ["Successful survival and reproduction of prey organisms depend on their ability to detect their potential predators accurately and respond effectively with suitable defences. Predator detection can be innate or can be acquired through learning. We studied prey-predator interactions in the larval bronzed frogs (*Sylvirana temporalis*), which have the innate ability to detect certain predators. We conducted a series of experiments to determine if the larval *S. temporalis* rely solely on innate predator (*Bradinopyga geminata*) detection mechanisms or can also learn to use more specific cues such as conspecific alarm cues for the purpose. The results of our study clearly indicate that larval *S. temporalis* use both innate and learned mechanisms for predator detection. Predator-naive tadpoles could detect kairomones alone as a potential threat and responded by reducing activity, suggesting an innate predator detection mechanism. Surprisingly, predator-naive tadpoles failed to detect conspecific alarm cues as a potential threat, but learned to do so through experience. After acquiring the ability to detect conspecific alarm cues, they could associate novel predator cues with conspecific alarm cues. Further, post feeding stages of larval *S. temporalis* are sensitive for learning to detect conspecific alarm cues to label novel predators." (2014): Diversity of mosquitoes and the aquatic insects associated with their oviposition sites along the Pacific coast of Mexico . *Parasites & Vectors* 2014, 7:41 doi:10.1186/1756-3305-7-41 : 31 pp. (in English) ["Background: The abundance, richness and diversity of mosquitoes and aquatic insects associated with their oviposition sites were surveyed along eight states of the Pacific coast of Mexico. Diversity was estimated using the Shannon index (H'), similarity measures and cluster analysis. Methods: Oviposition sites were sampled during 2–3 months per year, over a three year period. Field: collected larvae and pupae were reared and identified to species following adult emergence. Aquatic insects present at oviposition sites were also collected, counted and identified to species or genus. Results: In total, 15 genera and 74 species of mosquitoes were identified: *Anopheles pseudopunctipennis*, *An. albimanus* and *Aedes aegypti* were the most

abundant and widely distributed species, representing 47% of total mosquito individuals sampled. New species records for certain states are reported. Anopheline diversity was lowest in Sinaloa state ($H' = 0.54$) and highest in Chiapas ($H' = 1.61$) and Michoacán ($H' = 1.56$), whereas culicid diversity was lowest in Michoacán ($H' = 1.93$), Colima ($H' = 1.95$), Sinaloa ($H' = 1.99$) and Jalisco ($H' = 2.01$) and highest in Chiapas ($H' = 2.66$). In total, 10 orders, 57 families, 166 genera and 248 species of aquatic insects were identified in samples. Aquatic insect diversity was highest in Chiapas, Oaxaca and Michoacán ($H' = 3.60-3.75$). Mosquito larval/pupal abundance was not correlated with that of predatory Coleoptera and Hemiptera. Conclusion: This represents the first update on the diversity and geographic distribution of the mosquitoes and aquatic insects of Mexico in over five decades. This information has been cataloged in Mexico's National Biodiversity Information System (SNIB-CONABIO) for public inspection." 15096. Chakravorty, P.P.; Sinha, M.; and Chakraborty, S.K. (2014): Impact of industrial effluent on water quality and benthic macro invertebrate diversity in fresh water ponds in Midnapore district of west Bengal, India. *Journal of Entomology and Zoology Studies* 2(3): 93-101. (in English) ["A study on the impact of industrial effluent discharge on the distribution and biodiversity of benthic macro-invertebrates and water quality of a fresh water pond, in Gokulpur, West Bengal, India near Tata metaliks (a metal refinery) was carried out during April 2009-March 2010. Two ponds were chosen for this study of which one was used as control. Comparing the physico-chemical parameters in two ponds it was seen that pond G had higher hardness, total suspended solid, pH, phosphate, hydrogen sulphide, cyanide, heavy metals like lead, cadmium and mercury. The total no of macro-benthic taxa and their overall richness indices and diversity indices were higher at pond in Santipukur, (44 taxa) than pond in Gokulpur (22 taxa). The pond S was dominated by Ephemeroptera, Hemiptera where as other order found in small quantities included Coleoptera, Diptera, Molluscs, Crustacea and Odonata (*Urothermis signata*, *Anax* sp., *Enallagma* sp., *Pseudagrion* sp., *Ischnura* sp., *Caliagrion* sp.) On the other hand pond G was mainly dominated by tolerant Diptera and Hemiptera. The relationship between physicochemical parameter and macrobenthic data were investigated by Pearson correlation analysis. This statistical analysis showed that richness and diversity indices in pond G were mainly influenced by water hardness, total suspended solid, phosphate, hydrogen sulphide, lead and cyanide. It was also seen that a lot of species that were present in pond S were absent in pond G. CCA ordination biplot showed the presence of benthic macro-invertebrates in pond G was due to their strong and positive correlation with environmental variables." (Authors)] Address:

15100. Dallai, R. (2014): Overview on spermatogenesis and sperm structure of Hexapoda. *Arthropod Structure & Development* 43: 257-290. (in English) ["The main characteristics of the sperm structure of Hexapoda are reported in the review. Data are dealing with the process of spermatogenesis, including the aberrant models giving rise to a reduced number of sperm cells. The sperm heteromorphism and the giant sperm exceeding the usual sperm size for length and width are considered. The characteristics of several components of a typical insect sperm are described: the plasma membrane and its glycocalyx, the nucleus, the centriole region and the centriole adjunct, the accessory

bodies, the mitochondrial derivatives and the flagellar axoneme. Finally, a detailed description of the main sperm features of each hexapodan group is given with emphasis on the flagellar components considered to have great importance in phylogenetic considerations. This study may be also useful to those requiring an introduction to hexapod reproduction. ... 9.3. The Paleoptera: The two groups Odonata and Ephemeroptera exhibit a quite different sperm structure. The former shares many of the sperm characters present in the neopteran insects: a bi-layered acrosome (Fig. 2B), elongated nucleus, a centriole with microtubular triplets, expanded centriole adjunct material, a coiled flagellum with a 9 + 9+2 axoneme provided with accessory tubules with 16 protofilaments in their tubular wall, two mitochondrial derivatives and two accessory bodies (Fig. 11D) (Jamieson et al., 1999; Dallai et al., 2006). (Fig. 11: "Sperm tail of the dragonfly *Calopteryx* sp. (Odonata) with accessory bodies (ab), mitochondria (m) and accessory tubules with 16 protofilaments.") The sperm of Ephemeroptera, instead, show many autapomorphies: a mono-layered acrosome (Fig. 2C), a cylindrical nucleus, a centriole with triplets giving rise to a 9 + 9+0 flagellar axoneme, absence of central tubules and with large central sheath (Fig. 11C). Axonemal doublets have only inner dynein arms and accessory tubules show 13 protofilaments (Fig. 11C). A single mitochondrion and two crystalline accessory bodies are present (Jamieson, 1987; Dallai et al., 2006). These sperm are motile and, in Cloeon at least, mature sperm give rise to bundles (Lupetti et al., 2011). In the family Leptophlebiidae, as may be expected when the axoneme loses some key elements (here the central tubules and outer dynein arms) sperm are aflagellate and immotile (Gaino and Mazzini, 1991; Dallai et al., 2006; Brito et al., 2011). The two groups Ephemeroptera and Odonata, from a spermatological perspective, appear to be less similar than a common origin would suggest, in fact supporting the Metapterygota (Odonata + Neoptera) (Staniczek, 2000)." 15101. Damerow, J.F. (2014): Diversity and distribution of California dragonflies and other aquatic taxa over the past century. Ph.D., University of California, Berkeley: 155 pp. (in English) ["Climate and land-use change have altered and continue to affect the diversity, composition, and distribution of freshwater organisms throughout the world. This is particularly true in arid and semi-arid regions, where aquatic organisms may experience more pronounced reductions in available habitat with declines in precipitation, increases in water demand, and habitat degradation through human land-use. However, documentation of changes in taxonomic assemblages over long-time periods has been rare because of the difficulty in obtaining historical occurrence data. This dissertation used data from previously published literature, a resurvey study, museum specimens, and enthusiast sightings to document changes in the occurrence rates and distribution of freshwater organisms throughout California over the past century. Summary information regarding

freshwater taxa known to occur in California did not previously exist in a central publication. I therefore conducted a review of several primary groups of stream organisms found in the Mediterranean region of California and statewide. For this work, I gathered data from a variety of literature sources and museum specimens to summarize species composition and endemism in the region, and to identify data gaps and conservation priorities for the examined groups. The remainder of this dissertation focuses largely on changes in Odonata species diversity, composition, and occurrence rates over time in California. This charismatic group was ideal for study of change over time because of their relatively low diversity, well-known taxonomy, and the existence of sufficient historical and current specimen records and more recent enthusiast sightings of odonates. I conducted a resurvey of sites originally sampled for Odonata by Clarence H. Kennedy 1914-1915. This work involved surveys of odonates at 81 sites throughout central California and northwestern Nevada, 45 of which were directly comparable to Kennedy's original sites. I found that while site-level species richness has not changed significantly, assemblages have become more homogeneous across sites. Habitat generalists have generally expanded in the extent of their distribution while habitat specialists have declined. In examining current local and regional factors influencing the occurrence of Odonata species in this region, I found that species occurrence was higher during site visits with higher degree-days, especially for highly mobile groups, including dragonflies and migratory species. The probability of presence across species was lower in highly urban sites, particularly for habitat specialists. Overall, both regional and local factors influenced the occurrence of odonates in the study with implications for conservation. A large component of this dissertation included development and analysis of a database of over 33,000 Odonata occurrence records throughout California over the past century. This database included specimen records from museums in California and large odonate collections elsewhere, as well as statewide enthusiast sightings from recent years. I noted that these unstandardized data contain biases with regards to uneven sampling effort, which must be addressed in analysis. Subsequent analyses of occurrence records before and after 1975 indicated that Odonata distribution may have generally shifted northwards with temperature warming and to lower minimum elevations in response to increased summer water-availability in low-elevation agricultural regions. Similar to results from the resurvey study, the museum specimen data indicated that highly mobile migratory species have increased while habitat specialists have declined. I concluded that a combination of sampling biases, species traits, and climate that have influenced the probability of detection of Odonata species over the last century." (Author)]

15102. Darwall, W.; Carrizo, S.; Numa, C.; Barrios, V.; Freyhof, J.; Smith, K. (2014): Freshwater Key Biodiversity Areas in the Mediterranean Basin Hotspot. Informing species conservation and development planning in freshwater ecosystems. Cambridge, UK and Malaga, Spain: IUCN: x +

86 pp. (in English, with French, Spanish, Arabian, Croatian and Turkish summaries) ["Executive summary: The Mediterranean Basin Biodiversity Hotspot is well known for its globally important biodiversity. The freshwater biodiversity in the Hotspot, not previously widely recognized for its importance, is confirmed here to be unusually diverse and highly threatened, with many species endemic to individual rivers, streams, springs, wetlands and lakes across the region. Key Biodiversity Areas (KBAs) are areas contributing significantly to the global persistence of biodiversity. Based on published information on species conservation status and distributions (source IUCN Red List of Threatened Species) [KBA trigger species are i) freshwater fishes; ii) freshwater molluscs; iii) Odonata and iv) aquatic plants.], 90% of the 3,894 river/lake sub-catchments considered were found likely to meet the criteria qualifying them as Freshwater KBAs. The primary threats to freshwater species across the hotspot are increasing severity of droughts, hydrological alterations following construction of dams, over-abstraction of surface and ground waters, water pollution and invasive species. The impacts of these types of threat tend to spread rapidly throughout catchments such that localized conservation actions restricted to limited parts of a catchment will often fail to address these threats. For this reason the appropriate management unit for most freshwater KBAs is a sub-catchment, or a group of connected sub-catchments. The main criteria employed for a sub-catchment to qualify as a 'proposed KBA' were the presence of threatened or restricted range species, or an ecoregion-restricted community of species. Subsequent evaluation of these proposed KBAs for the three sub-regions of the Hotspot eligible for CEPF funding was conducted through three workshops involving 39 stakeholders in the Balkans (Jahorina, Bosnia and Herzegovina), Turkey and Levant (Azraq, Jordan), and northern Africa (Marrakesh, Morocco). One hundred and sixty-seven freshwater KBAs, covering a total area of 302,557 km² were confirmed as valid freshwater KBAs. Of these, 40 KBAs also meet the criteria qualifying them as Alliance for Zero Extinction (AZE) sites where immediate conservation actions are required if a species present in the KBA is not to become globally extinct in the near future. All proposed and validated KBAs are now publicly available for viewing on the World Biodiversity DataBase website (www.birdlife.org/datazone/freshwater). The current level of inclusion of validated freshwater KBAs within existing protected areas or other KBAs was found to be extremely low. Seventy-five per cent of the total area of these KBAs was found to lie outside the boundaries of any pre-existing protected areas or other KBAs, including 15 freshwater KBAs for which there is no overlap at all. Through this project freshwater KBAs have now been identified, mapped and validated throughout much of the Mediterranean Hotspot. It is now important to raise awareness of their status as validated freshwater KBAs and to develop plans for appropriate conservation actions at these sites. One hundred and eighty-eight potential Site Champions have been identified by stakeholders as individuals/organizations best placed to raise awareness of the existence of the KBAs and the issues faced with respect to threats to biodiversity, and to help

implement the required actions to safeguard these globally important sites. Specific recommendations for conservation actions are mainly focused on improving management of the hydrology of these KBAs, many of which are currently or potentially impacted by over-abstraction and diversion of water, construction of dams, and drought. KBAs need to be managed to ensure Environmental Flows are sufficient to support these fragile freshwater ecosystems and they should be implemented as part of catchment-wide Integrated River Basin Management planning which takes account of the wide range of uses of water across all sectors. There are also important knowledge gaps in site and basin-specific species distributions of many threatened species, and many countries do not yet have baseline inventories of their inland water ecosystems and species assemblages. It is very possible that many new KBAs will be discovered if these biodiversity inventories progress. In conclusion, the Mediterranean Basin Hotspot is found to be globally important for its freshwater biodiversity. This biodiversity is highly threatened largely due to the conflicting demands upon a diminishing supply of fresh water which is further exacerbated by the increased severity of drought across the region. Unless the recommendations given above are followed and Site Champions are mobilized to raise awareness of these globally important freshwater KBAs, species will almost certainly be lost in the very near future. Solutions are available but the willingness to adopt them has to be encouraged. Freshwater species are most often out of sight and out of mind so raising awareness of their presence, the threats they face, and the necessary conservation actions are fundamental to the persistence of freshwater biodiversity in the Mediterranean Hotspot." (Authors) The following odonate trigger species were selected: Turkey and Levant: none; Balkans: *Coenagrion intermedium*, *Ceragrion georgifreyi*, *Pyrrhosoma elisabethae*, *Boyeria cretensis*; North Africa: *Calopteryx exul*, *Cordulegaster princeps*; Gomphus lucasii] Address: Available from: IUCN Centre for Mediterranean Cooperation, C/ Marie Curie 22, 29590 Campanillas, Malaga, Spain. www.iucn.org/mediterranean; www.iucn.org/publications

15104. Elias, J.D.; Ijumba, J.N.; Mgaya, Y.N.; Mambo, F.A. (2014): Study on freshwater macroinvertebrates of some Tanzanian rivers as a basis for developing biomonitoring index for assessing pollution in tropical African regions. Journal of Ecosystems Volume 2014, Article ID 985389, <http://dx.doi.org/10.1155/2014/985389>: 8 pp. (in English) ["Macroinvertebrates and physico-chemical parameters were assessed at 15 sites along five rivers in Kilimanjaro region, Tanzania, with the aim of understanding their eco-

logical status and set a base to the development of a biological index for tropical regions. Investigated rivers occur within Pangani basin include Karanga, Rau, Lumbanga, Sere, and Umbwe. Sampling sites were categorized according to the level of water and habitat quality as follows: reference or least impacted (4 sites), moderately impacted (5 sites) and highly impacted (6 sites) sites. A total of 12,527 macroinvertebrates belonging to 13 orders and 48 families were recorded. The highest total abundance of 4,110 individuals per m² was found in Karanga river, while Umbwe River had the lowest with 1,203 individuals per m². Chironomidae was the most abundant family (2,588 individuals per m²) and the least were Hydridae and Thiaridae, each having 5 individuals per m². High numbers of taxa were noted among the Orders: Ephemeroptera (8), Odonata (8), Diptera (7) and Trichoptera (6). In conclusion, orders with greater diversity of macroinvertebrate families offer a wide range of tolerance to pollution, thus can potentially be used to develop a biomonitoring index for evaluating pollution in Tropical African rivers." 15107. Fauziyah, S.; Alam, C.; Soesilohadi, R.C.H.; Retnoaji, B.; Alam, P. (2014): Morphological and mechanical characterisation of the hindwing nodus from the Libellulidae family of dragonfly (Indonesia). *Arthropod Structure &*

Development 43(5): 415-422. (in English) ["In this communication, the morphologies and mechanical characteristics of nodi from the hindwings of seven Indonesian Libellulidae dragonfly species are identified (*Acisoma panorpoides* ascalophoides, *Brachythemis contaminata*, *Crocothemis servilia*, *Potamarcha congener*, *Pantala flavescens*, *Orthetrum sabina*, *Neurothemis ramburii*). Geometrical analyses reveal that in all species, the shape of dorsal face resilin is relatively long and thin while ventral face resilin covers a greater surface area than dorsal face resilin, and is shaped like a hook. Finite element analyses reveal that the magnitude of strain energy may differ considerably between species, even though the locations of highest strain energy are usually the same. Importantly, a correlation is found to exist between the mechanical forces that build up in the resilin, the face under investigation (dorsal or ventral) and the elongational shape factor of the resilin." 15108. Furlan, N.E (2014): Life histories, diets, and secondary production of Odonata along a temperature gradient on the Copper River Delta, Alaska. MSc thesis, Loyola University Chicago: 79 pp. (in English) ["Dragonflies (Odonata: Epiprocta) and damselflies (Odonata: Zygoptera) are a conspicuous aspect of the biota in ponds on southcentral Alaska's Copper River Delta (CRD). Odonate densities, secondary production, and diets were assessed in sixteen ponds classified by delta region (east vs. west) and landscape type (outwash plain (OP) vs uplifted marsh (UM)). *Enallagma boreale* comprised 48.5% of collected odonates. *Leucorrhinia hudsonica* and *Aeshna juncea* comprised 36.6% and 10.4% of collected odonates, respectively. *L. hudsonica* densities and secondary production were significantly higher ($p < 0.001$) in west UM ponds than in other pond types. Ostracods (Ostracoda) and water boatmen (Corixidae) dominated west OP *A. juncea* diets. Midge larvae (Chironomidae) dominated *A. juncea* diets in remaining pond types, occurring in 68% of foreguts. 27% of *A. juncea* foreguts demonstrated intraguild predation, and 6% of foreguts demonstrated cannibalism. Foreguts containing threespine stickleback (*Gasterosteus aculeatus*) revealed *A. juncea*'s apex predator role in CRD ponds." (Authors)] Address: not stated

15109. Gauci, C. (2014): A review of the Odonata of the Maltese Islands. J. Br. Dragonfly Society 30(2): 79-109. (in English) ["This paper is the result of five years of detailed observations of Odonata at several sites in the Maltese Islands. It updates the status and relative abundance of the various species. There is currently only one zygopteran *Ischnura genei* established on the Islands. *Calopteryx virgo* is considered a vagrant, while the occurrence of *C. haemorrhoidalis* is considered to be highly doubtful. There are nine species of anisopterans which are established in the Islands, these being *Anax imperator*, *A. parthenope*, *Orthetrum cancellatum*, *O. coerulescens*, *O. trinacria*, *Sympetrum fonscolombii*, *Crocothemis erythraea*, *Trithemis annu-*

lata and *Selysiothemis nigra*. Three more: *Orthetrum nitidissime*, *O. chrysostigma* and *Pantala flavescens*, have recently been added to the Islands' list, while two - *Orthetrum brunneum* and *Sympetrum striolatum* - which were formerly considered common, are now very rare. *Anax ephippiger* is a fairly regular migrant, appearing in considerable numbers in some years. *Aeshna mixta* is rare but might be on the verge of establishing itself on the Islands, following a recent spate of records, including ovipositing females. Various inaccuracies and conflicting statements appearing in previous contributions are corrected. Observations on behaviour are included where these are of special interest as well as where they are in contradiction of what has been stated in the literature." (Author)] Address: Gauci, C., 28. 15115. Karaouzas, I.; Dimitriou, E.; Lampou, A.; Colombari, E. (2014): Seasonal and spatial patterns of macroinvertebrate assemblages and environmental conditions in Mediterranean temporary ponds in Greece. *Limnology* 16: 41-53. (in English) ["Mediterranean temporary ponds in Greece have been neglected, and only recently has attention been drawn to their protection and conservation. In this study, the macroinvertebrate fauna of the Mediterranean temporary ponds of western Crete was examined for the first time. In particular, the seasonal and spatial patterns of macroinvertebrate communities were assessed along with the spatio-temporal variation of their environmental conditions and hydroperiod variation. Benthic fauna and abiotic (physicochemical, hydroperiod) data were monitored for 3 years (2006–2008). A total of 63 macroinvertebrate taxa belonging to 33 families were recorded, with *Plea minutissima*, *Berosus affinis*, *Pericoma* sp., *Culex* sp., Chironomidae and Cyprididae being the most abundant. Nutrient pollution was significant in the ponds situated near agricultural areas and could thus explain the poor species richness. NMDS showed a clear spatial and temporal distinction between

lowland and upland sites. Heteroptera species were exclusively encountered in spring, while Coleoptera larvae and adults were present in all seasons, with adults being more abundant during winter. Ordination analysis revealed significant seasonal and inter-annual differences in macroinvertebrate assemblage structure, as confirmed by ANOSIM ($R = 0.965$, $p = 0.001$). Species richness was relatively lower compared to temporary ponds from other regions because of their isolated character, unpredictable hydroperiod and degraded water quality. This study highlights that these fragile ecosystems sustain a unique invertebrate fauna able to endure pond drying by several survival traits and therefore their conservation and protection is necessary." (Authors) Taxa - including Odonata - are treated at the family level.] Address: Karaouzas, I., Hellenic Centre for Marine Research, Institute of Marine Biological Resources and Inland Waters, 46.7 km Athens-Sounio Av., 19013, Anavissos, Attica, Greece. 15117. Khazan, E.S. (2014): Tests of biological corridor efficacy for conservation of a Neotropical giant damselfly. *Biological Conservation* 177: 117-125. (in English) ["Deforestation and forest fragmentation are important drivers of global biodiversity loss and negatively impact ecosystem health and landscape continuity. One approach to reducing these impacts is the establishment of biological corridors. Studies on corridor efficacy have been limited to a small

subset of taxa; while important, these data can rarely be extrapolated to other systems. I tested whether *Megaloprepus caerulatus*, a giant tree-hole breeding damselfly adapted to mature Neotropical forests, can and does disperse from mature forest to fragments that are components of an established corridor. I monitored presence of *M. caerulatus* in four secondary forest fragments of the San Juan-La Selva biological corridor network and in the contiguous La Selva forest. I compared densities of adult *M. caerulatus* and larval presence in artificial and natural breeding sites over the course of one year. None of the artificial holes in fragments were colonized by *M. caerulatus* whereas at La Selva 25% of artificial holes and 63% of natural tree holes were colonized. I tested *M. caerulatus*'s ability to fly over pasture between fragments with a dispersal challenge experiment. Although the damselfly successfully crossed gaps of 25 m, it had difficulty traversing gaps as narrow as 50–100 m. Based on analysis of 360 photos taken from each release distance, the forest edge was less distinguishable from distances P50 m. These results suggest limited conservation utility of existing biological corridor networks for *M. caerulatus*." 15118. Kiauta, B. (2014): Sketches for the dragonfly fauna (Insecta: Odonata) of the metropolis of Ljubljana, Slovenia. *Natura Sloveniae* 16(1): 15-40. (in Slovene, with English summary) ["An annotated list of 49 species, recorded within the boundaries of the Municipality of Ljubljana, is presented, along with brief comments on selected taxa. A comprehensive regional bibliography, covering the 1763-2010 period, is appended. Biogeographically, the fauna has a northern Mediterranean character, marked by the occurrence of *Calopteryx virgo padana*, *Cordulegaster heros* and *Somatochlora meridionalis*. The increase of biodiversity from the urbanized city centre (13 species), towards the suburbs (38 species) and the adjacent rural neighbourhood (49 species) is emphasized. The ecological features of the odonate assemblage of the Ljubljana city centre are compared with those in the centres of Klagenfurt (Austria: 21 species) and Trieste (Italy: 8 species). Some pending problems in the field of species-, habitat- and biodiversity conservation in selected localities are outlined, with particular reference to the recreational boating on the Ljubljanica river, inadequate management of the Tivoli pond and to the impoundment and regulation of the Gradašica and Glinšica streams." 15123. Md Rawi, C.S.; Al-Shami, S.A.; Madrus, M.R.; Ahmad, A.H. (2014): Biological and ecological diversity of aquatic macroinvertebrates in response to hydrological and physicochemical parameters in tropical forest streams of Gunung Tebu, Malaysia: implications for ecohydrological assessment. *Ecohydrology* 7(2): 496-507. (in English) ["In

this study, we have investigated the effects of some hydrological and physicochemical parameters such as water quality, velocity, water depth, river width, water pH, water temperature, ammonia-N, biochemical oxygen demand (BOD), chemical oxygen demand (COD) and dissolved oxygen (DO) on diversity of aquatic macroinvertebrates in forest streams of Gunung Tebu (GT), Malaysia. The results of canonical correspondence analysis identified three groups of the aquatic macroinvertebrates according to their relationships with hydrological and physicochemical parameters. The stream velocity, water quality (i.e. DO, BOD and ammonia-N) in addition to canopy cover, total habitat score and substrate quality were the determinant factors controlling the diversity pattern of the aquatic macroinvertebrates in GT streams. Alteration in the hydrological and physicochemical parameters showed to influence the ecological diversity of the aquatic macroinvertebrates in GT streams. The predators were found to be highly associated with the elevated concentrations of BOD and COD. Shredders were positively correlated with pH, stream velocity, DO and habitat quality indicators (total habitat score, embeddedness, epifaunal and canopy cover). However, the collector-gatherers correlated negatively with all of these parameters. It was concluded that stream velocity, substrate structure and water quality were strong attributes for variation in aquatic macroinvertebrate assemblage structure in tropical forest streams of GT." (Authors) Odonata are treated at genus level.] Address: Salman Abdo Al-Shami, School of Biological Sciences, Universiti Sains Malaysia (USM), 11800 Penang, Malaysia. J.; Wang, J.; Kjer, K.M.; Zhou, X. (2014): Phylogenomics resolves the timing and pattern of insect evolution. *Science* 346(6210): 763-767. (in English) ["Insects are the most speciose group of animals, but the phylogenetic relationships of many major lineages remain unresolved. We inferred the phylogeny of insects from 1478 protein-coding genes. Phylogenomic analyses of nucleotide and amino acid sequences, with site-specific nucleotide or domain-specific amino acid substitution models, produced statistically robust and congruent results resolving previously controversial phylogenetic relationships. We dated the origin of insects to the Early Ordovician [~479 million years ago (Ma)], of insect flight to the Early Devonian (~406 Ma), of major extant lineages to the Mississippian (~345 Ma), and the major diversification of holometabolous insects to the Early Cretaceous. Our phylogenomic study provides a comprehensive reliable scaffold for future comparative analyses of evolutionary innovations among insects." 15127. Nakanishi, K.; Nishida, T.; Kon, M.; Sawada, H. (2014): Effects of environmental factors on the species composition of aquatic insects in irrigation ponds. *Entomological Science* 17(2): 251-261. (in English) ["Although irrigation ponds contribute to the conservation of aquatic biodiversity, they have experienced declines in recent years. We therefore examined the relationships between various environmental factors and the community composition of aquatic insects, specifically insect predators, in irrigation ponds to gain knowledge that would aid in the conservation and restoration of biodiversity. We selected Odonata, Hemiptera and Coleoptera as target taxonomic groups and conducted censuses of these groups in 21 ponds in Shiga, central Japan. In total, we collected 30 and 10 species (or species groups) of Odonata and Hemiptera, respectively, and 17 species of Coleoptera. A partial canonical correspondence analysis revealed that the following four environmental factors significantly affected the species composition of aquatic insect communities: the number of emergent plant species, percent concrete revetment, presence of litter and peripheral length. Among these variables, the number of emergent plant species was the most potent factor, perhaps because emergent plants serve as sites for oviposition and emergence, and provide refugia for aquatic insects (odonate nymphs in particular). In contrast, some species specifically inhabited sites poor in emergent plants. This study shows that reductions in concrete revetments are necessary for the conservation of biodiversity. This

would lead to increases in the number of aquatic plant species, which provide habitats and oviposition sites for many aquatic insects. Furthermore, to enrich the local biodiversity of aquatic insects, groups of irrigation ponds with different environments are needed." (2014): Structure and abundance of "interrhizon" invertebrates in an oxbow lake in the peat swamp area of Central Kalimantan, Indonesia. *Limnology* 15: 191-197. (in English) ["The faunal composition of "interrhizon" invertebrate communities associated with submerged parts of three kinds of macrophytes, *Eichhornia crassipes*, *Gramineae* spp. and *Polygonum tomentosum*, were studied in an oxbow lake, Lake Tundai, with acidic water (pH 3.9–4.4) in the peat swamp area of Central Kalimantan. The pH, turbidity, and chlorophyll-a concentration in the surface waters tended to be higher in macrophyte stands than in open waters near the

stands. Thirty-one taxa belonging to three groups of invertebrates, Arachnida, Insecta (including "Coenagrionidae" and "Libellulidae"), especially chironomids, and Isopoda, were found from the root systems, of which insects were the most abundant in every macrophyte stand. The interrhizon invertebrates accounted for 0.16–8.7 g wet wt m² among three vegetational stands. The diversity and abundance of interrhizon invertebrates are low in Lake Tundai; this could be due to low pH and/or low productivity in the lake water." 15130. Oliver-Morales, C.; Abarca-García, C.A.; Pozos-Zepeda, L.F. (2014): The differential use of habitat between sexes in a *Ischnura* sp. (Odonata: Coenagrionidae) in the Ciénaga of Almoloya del Río, Estado de México. *Entomología Mexicana* 1: 447-451. (in Spanish, with English summary) ["Field observations about the use of habitat allow us to understand the importance of biotic and abiotic interactions. The main objective of this work was describing quantitatively the differences in the use of habitat between males and females of a species of odonates of *Ischnura* spp. Genus. The work has done in a swamp of Almoloya del Río - Lerma, Estado de México. The fieldwork was made in two sites at the same period of time, in the grassland and in the edge of the pond. Our observations revealed higher quantity of females (88.43 % of females and 11% of males) in grassland than into the swamp (25.86 % of females and 74.13% of males). In overall our results shows that the females of *Ischnura* sp. prefers the grassland zones and on contrary, males prefers the pond. We proposed that males occupied pond area, because in these sites they establish territories in where competed for access to a coupled. If this is true, then the use of habitat could be an important selection pressure to establish the degree of competition for access to a partner." (Authors)] Address: Oliver-Morales, Celia, Depto de Ciencias Ambientales, Universidad Autónoma Metropolitana-Unidad Lerma. 15131. Orlofske, J.M.; Baird, D.J. (2014): A geometric morphometric approach to establish body-shape trait criteria for aquatic insects. *Freshwater Science* 33(3): 978-994. (in English) ["Body shapes of aquatic insect larvae reflect phenotypic responses to complex environmental conditions and can be used to infer habitat properties and indicate natural and anthropogenic perturbations in river ecosystems. Investigation of relationships between body shape and physical-habitat characteristics has been restricted by a lack of an objective schema for quantitative characterization of body-shape variation. We present a functional ecological framework for body-shape classification based on defined criteria. We applied a geometric morphometric (GM) approach to the general classification of body shape in 4 morphologically diverse orders, Ephemeroptera (E), Plecoptera (P), Trichoptera (T), and Odonata (O) collected from 3 sites with contrasting hydrological and hydraulic characteristics.

We describe a robust classification of body shapes for E, P, and O, which possess a compartmentalized body plan, and suggest a preliminary classification for T. We compared GM body shapes with body-shape trait states available in trait databases and found discordance between the 2 classifications. We explored the value of GM body shapes to describe taxon shape structure of reference sites and to detect variation reflecting physical properties of the sites. GM body-shape classes can augment the trait states already available and enhance inference regarding habitat status. Patterns in the shape strategies of aquatic insects, particularly EPO taxa, can be used to extrapolate shape information for other taxonomic groups. GM provides a stable shape classification that can contribute to the description of different ecological strategies of aquatic insects. Expanding the scope of shape information available for many taxonomic groups can improve our understanding of how organism phenotype relates to environmental conditions and supports traits-based assessment. A geometric morphometric approach to establish body-shape trait criteria for aquatic insects." (Authors)] Address: Orlofske, Jessica, Canadian Rivers Inst., Dept Biology, P.O. Box 4400, 10 Bailey Drive, Univ. of New Brunswick, Fredericton, New Brunswick, Canada E3B 5A3. E-mail: j.orlofske@unb.ca

15132. Palacino-Rodríguez, F.; Contreras-Sánchez, N.A. (2014): Does experimental marking of wings influence resighting success in *Mesamphiagrion laterale* and *Erythrodiplax umbrata*? (Odonata: Coenagrionidae, Libellulidae). *Odonatologica* 43(3/4): 237-246. (in English) ["To investigate if experimental marking affects the probability of resighting, 1,610 individuals of *Mesamphiagrion laterale* (Selys, 1876) and 630 individuals of *Erythrodiplax umbrata* (Linnaeus, 1758) were marked at two sites in Colombia and analysed with respect to marking variables as follows: marking colour used, which wing was marked, and a combination, i.e. the interaction, of these two. The colour and the marked wing were varied, using a different wing each time, and red, black, blue, or green colour. The information was analyzed using contingency tables (Chi-square test) to compare the probability of resighting for individuals within a population marked with a specific colour or on a specific wing to the probability of resighting for all other individuals in the population. In *E. umbrata* the resighting probability ranged as follows: 90.1 to 95.7 % (marking colour type), 90.4 to 95.2 % (wing used), and 87.5 to 97.8 % (wing-colour combination). In the case of *M. laterale*, the resighting probability ranged as follows: 57.2 to 65.0 % (marking colour type), 58.8 to 65.6 % (wing used), and 51.0 to 82.0 % (wing-colour combination). The colour, wing, or combination of wing-colour used for marking didn't have an effect on the resighting probability, suggesting that the method and its variations are adequate to be used in mark-release-recapture studies on odonates. Recommendations are given on what has to be avoided to eliminate potential effects during the marking procedure." Popova, O.N.; Haritonov, A.Yu (2014): Disclosure of biotopical groups in the population of the dragonfly *Coenagrion armatum* (Charpentier, 1840). *Contemporary Problems of Ecology* 7(2): 175-181. (in English) ["The spatial temporal distributions of *C. armatum* in Lake Fadikha with edging overgrowth in the Barabinsk forest steppe are described. It is discovered that the local population of this species is divided into two biotopical groups. The specimens of one group develop in the water area and do not migrate to the shore after metamorphosis; in the other, dragonflies develop in the reeds and migrate to the shore for additional

feeding after metamorphosis." (Authors)] Address: Popova, Olga, Institute of Systematics and Ecology of Animals, Siberian Branch, Russian Academy of Sciences, ul. Frunze 11, Novosibirsk, 630091 Russia. E-mail: popova.olga.nik@gmail.com

15136. Preston, D.; Forstner, M.R.J. (2014): Aggregation status and cue type modify tadpole response to chemical cues. *Journal of Fish and Wildlife Management* 6(1): 199-207. (in English) ["Many anuran larvae exhibit an antipredator response to chemical cues released by potential predators. The genus *Bufo* is no exception, as many bufonids exhibit an antipredator response (e.g. reduction in activity) to the presence (recent and current) of predators. Using a mesocosm experiment in a field laboratory setting, we tested solo and groups of *Bufo* (*Incilius*) *nebulifer* tadpoles for an antipredator response to chemical cues produced by 1) the presence of anisopteran nymphs (kairomone cue) (*Anax junius*), and 2) the predation of conspecifics by anisopteran nymphs (a combination of diet and alarm cues, which we termed predation cue). We quantified the magnitude of the response by calculating response strength. We analyzed data with a blocked ANOVA followed by a Tukey's honestly significant difference analysis. We found that chemical cue type (kairomone vs predation) enhanced response strength, but aggregation status (solo vs group) did not. However, solo and groups of tadpoles reduced their activity in response to predation cues, whereas only solo tadpoles reduced their activity in response to kairomone cues, a heretofore unobserved phenomenon. Our results suggest that *B. nebulifer* tadpoles modulate their response to specific types of chemical cues depending on their aggregation status. As reduced activity comes at a cost to resource acquisition and growth, aggregation status may indirectly affect the life history of *B. nebulifer*." 15140. Ryazanova, G.I. (2014): Seasonal variation of wing venation in dragonfly populations (Odonata). *Eurasian Journal of Entomology* 13(4): 334-338. (in Russian, with English summary) ["The variability of the number of wing cells has been studied in four populations of the damselfly *Ischnura elegans*. The dynamics of this characteristic has been described within one season and between seasons. The number of cells of the wing at the beginning of the season of imago flight significantly higher than at its end. The number of cells of the wings of different populations may differ significantly even at the same time. However, inter-seasonal changes in the number of wing cells in the different populations have different directions and scales, not allowing the use of particular wing venation as a sustainable comparative population characteristics. Similar variability of wing venation in the season found in species *Coenagrion puella* and *C. hastulatum*. We discuss a latitude spread of the described phenomenon for dragonflies." 15141. Sawada, K.; Yamahira, K.; Kuriwada, T. (2014): Interpopulation variation in female color-type frequency of *Ischnura senegalensis* in Okinawa Island, Japan (Odonata: Coenagrionidae). *Odonatologica* 43(3/4): 227-235. (in English) ["*I. senegalensis* has two female colour-types: gynochromes, which are brown, and androchromes, which are green and similar in appearance to conspecific males. *Ischnura senegalensis* females from Okinawa Island, a

small island in the Ryukyu Archipelago, Japan, show colour-type frequencies that vary greatly, even among adjacent local populations. For example, androchrome frequencies were very low (0–4.3 %) in northern populations of the island. However, in the southern populations androchrome frequencies were high and ranged widely (0–67.2 %). Periodical surveys from 2011 to 2013 of two adjacent southern populations revealed that the frequency of colour-type remained constant over time. To our knowledge, this is the first study of temporally stable and extremely high interpopulation variation in female colour-type frequency in Odonata. We discuss possible reasons for the evolution of such high interpopulation variation in colour-type frequency." (2014): Larvicidal activity of Brazilian plant essential oils against coenagrionidae larvae. *Journal of Economic Entomology* 107(4): 1713-1720. (in English, with Spanish summary) ["Odonate larvae can be serious pests that attack fish larvae, postlarvae, and fingerlings in fish culture tanks, causing significant loss in the supply and production of juveniles. This study reports a screen of the essential oils (EOs) of *Nectandra megapotamica* (Sprengel) Mez,

Nectandra grandiflora Nees, *Hesperozygis ringens* (Benth) Epling, *Ocimum gratissimum* L., *Aloysia gratissima* (Gillies & Hooker) Troncoso, and *Lippia sidoides* Chamisso against Coenagrionidae larvae. In addition, the most effective EO and its 50% lethal concentration (LC50) and chemical analysis are described. The larvae of *Acanthagrion Selys*, *Homeoura Kennedy*, *Ischnura Charpentier*, and *Oxyagrion Selys* were used to assess the EO effects. EO obtained from *H. ringens*, *O. gratissimum*, and *L. sidoides* showed the highest larvicidal effects at 19 h of treatment. The major constituents of the EO of *H. ringens* include pulegone and limonene, while eugenol and -ocimene predominate in the EO of *O. gratissimum*, and carvacrol and -cymene were the major compounds of the EO of *L. sidoides*. Leaf EOs from *H. ringens*, *O. gratissimum*, and *L. sidoides* showed activity against Coenagrionidae larvae at similar concentrations with LC50s of 62.92, 75.05, and 51.65 l liter⁻¹, respectively, and these were considered the most promising treatments." 15146. Skolka, M. (2014): *Selysiothemis nigra* (Odonata) - new species for Danube delta. Popa, L. O., C. Adam, G. Chisamera, E. Iorgu, D. Murariu, O. P. Popa (eds) 2014. International Zoological Congress of "Grigore Antipa" Museum - Book of abstracts. "Grigore Antipa" National Museum of Natural History, Bucharest, Romania: 121. (in English) [Romania; Verbatim: In the spring of 2014, during a monitoring survey of the sandy habitats in *Selysiothemis nigra*, is a IUCN Red List Least Concern species. This species is present in Central Asia, Middle East and Mediterranean area. In the past, this species was probably spread all around the Tethys Sea. In the Mediterranean area, the distribution of *Selysiothemis nigra*, is very scattered. It is mentioned from small areas in all Mediterranean basin: Portugal, Spain – mainland and eastern part, Balearic Islands, Sicily, Malta, Sardinia, parts of Italy, Adriatic coast of Croatia and Slovenia, Greece, Cyprus, Crete. In the Black Sea area, this species is present in the southern part of Bulgaria, Crimean region and Odessa area. Also, this species is present in mainland Russia, near Ural Mountains. For the Black Sea area, *Selysiothemis nigra* is a new species. It was mentioned only in 2002 for Bulgaria and Ukraine. In Romania, this species was mentioned only in 2013, by a British bird-watcher from Danube Delta, on his blog. This year, many specimens, all females, were observed in sandy habitats dominated by *Leymus sabulosus* and *Crambe maritima* among other dragonflies as *Aeshna isosceles*, *Anax parthenope*, *Anax imperator*, *Orthetrum cancellatum*, *Crocothemis erythraea*, *Ischnura elegans*, *Sympetrum vulgatum*, *S. sanguineum*, *Lestes macrostigma*, *Erythromma najas*, *E. viridulum*, *E. lindenii* and *Coenagrion* sp. The presence of a high number of specimens of *Selysiothemis nigra* on the sandbelt that isolate the paramarine lakes from the Black Sea, and the mentions of this species from Ukraine and Bulgaria suggest that this species extended their range northwards in the last decade. In this case, we are in front of a

new example of climate changes induced regional evolutions.] Address: Skolka, M., "Ovidius" University of Constanta. Natural Sciences Department. 1 Aleea Universitatii. corp B. Constanta 900470. Romania E-mail: mskolka@gmail.com

15147. Stadler, G. (2014): Ein außergewöhnlich warmer Winter 2013/2014 mit den beiden Winterlibellen *Sympecma fusca* und *S. paedisca*. *Mercuriale* 14: 43-60. (in German, with English summary) ["Residence and activity patterns during hibernation of 27 adults of *Sympecma fusca* were observed and controlled 62 times from late autumn, 2013, until late winter, 2014. Whereas autumn temperatures were near average, the winter was characterised by exceptionally high temperatures. The study was carried out in the nature reserve "Lengwiler Weiher" in the vicinity of the southern shore of Lake Constance, Switzerland. Five specimens of *S. fusca* were captured, marked and released in November, 2013. Three out of these five individuals could be recorded several times until mid-March, 2014. On 23 February 2014, a remarkable observation was done: under cloudy conditions a specimen undertook a short flight although the current temperature was only 6.6° C. After midday the same day an individual could be observed feeding. Furthermore, in the end of February, 2014, few specimens of *S. paedisca* could be recorded, partly in the same habitat." 15149. Tajima, Y.; Watanabe, M. (2014): Seasonal variation of genital morphology and sperm removal in *Ischnura asiatica* (Odonata: Coenagrionidae). *Odonatologica* 43(3/4): 213-226. (in English) ["During copulation, *Ischnura asiatica* (Brauer, 1865) males remove the sperm of the females' previous mates from the spermatheca by stimulating vaginal sensilla thereby inducing sperm ejection. Because a wider penis head stimulates the vaginal sensilla more intensely, larger males with wider penis heads can remove much more sperm from the spermatheca. There are two distinct body sizes for spring (large) and summer (small) generations of *I. asiatica*. In the present study we show that in spring, males have wider penis heads and females have a higher number of vaginal sensilla as compared to summer

adults, suggesting that mating males remove more spermathecal sperm in spring than in summer. However, interrupted copulation experiments showed that females of the spring generation had a higher number of spermatozoa in both sperm storage organs than those of the summer generation. Solitary females of the spring generation also had higher numbers of spermatozoa stored than those of the summer generation, suggesting that spring females might have larger sperm storage organs than summer females. Although the removal rate of bursal sperm was almost the same between generations, the removal rate of spermathecal sperm in the summer generation was slightly higher than that in the spring generation. Consequently, spermatozoa derived from previously mated males have a higher probability of remaining in the sperm storage organs in spring than in summer-generation females. The size of sperm storage organs in females might be critical to understanding sperm displacement. This aspect of female anatomy has not been previously considered in studies of sperm competition in odonates." 15153. Wang, J.-F.; Chen, M.-Y.; Chaw, S.-M.; Morii, Y.; Yoshimura, M.; Sota, T.; Lin, C.-P. (2014): Complete mitochondrial genome of an enigmatic dragonfly, *Epiophlebia superstes* (Odonata, Epiophlebiidae). *Mitochondrial DNA* 26(5): 718-719. (in English) ["This study reported the 15,435 bp-long complete mitochondrial genome of the relict *Epiophlebia superstes* (Odonata, Epiophlebiidae), an enigmatic dragonfly of the paraphyletic 'Anisozygoptera' possessing characteristics similar to members of both extant odonate suborders, the Zygoptera and the Anisoptera. This mitogenome comprises the common set of 37 genes and an A_pT-rich control region, and has a gene arrangement identical to those of all available odonates. The genome contains three non-coding inter-genic spacers (s1-s3), which occurs in all of other known odonates, but it lacks the inter-genic spacer s5 typically found in the Anisoptera. This result suggests that *E. superstes* possesses a mitogenomic organization more closely related to that of the Zygoptera than that of the Anisoptera." 15156. Zurbrigg, E.; Brodo, I.; Cipriani, J.; Hanrahan, C., Maccenzie, A. (2014): The Ottawa Field-Naturalists' Club Awards for 2013, presented April 2014. *The Canadian Field-Naturalist* 128: 432-434. (in English) [Verbatim: Mary Stuart Education Award: Angelika Skevington The Mary Stuart Education Award is given in recognition of outstanding achievements in the field of natural history education in the Ottawa Region. Angela Skevington is the recipient of this award for 2013. Angela is a primary school teacher who is passionate about natural history education. For over 15 years she has taught a variety of grades in different schools, sharing her dedication to good environmental stewardship and her knowledge and wonder of nature with her students every day, every year. Currently Angela teaches a combined Grade 4/5 class at Huntley Centennial Public School in the village of Carp near Ottawa. Wherever she works, Angela has championed such environmental programs as EarthCare Canada and more recently Ontario EcoSchools. Last year her school was recognized with a silver level EcoSchool certification. This achievement required years of diligent effort on Angela's part to engage students and the school community in activities across the 6 areas of environmental practice rated by the EcoSchool Program, including waste minimization and energy conservation. Each school year, she instigates a student-led club (previously called an EarthCare Club, currently dubbed The Dragonflies) that undertakes environmental projects, such as a periodic audit of their school's energy and waste practices. If the audit indicates that there is a problem, such as improper waste disposal, then The Dragonflies club delivers classroom presentations to fellow students demonstrating the proper practice, such as how to separate garbage for recycling. The students in The Dragonflies club also put on plays at school assemblies to demonstrate proper energy and waste practices. Last year, Angela piloted "litterless lunches" with her class. The Dragonflies promoted the idea and this year the whole school is litter-free at lunch. There are many more examples. Through this hands-on practice, students learn how to be active environmental stewards. For the past 3 years, Angela has participated in Ottawa's Clean up the Capital Day. She enlisted classes that were interested in being involved, applied through the City of Ottawa to get materials (bags, gloves) and then they cleaned up the school grounds. On Earth Day, Angela has conducted student plays at the school assemblies featuring pollution, anti-littering, proper recycling. She also encourages the students to create and perform skits, songs and presentations. She does this every year to promote celebration of the natural environment and good environmental stewardship. Field trips and nature appreciation are important parts of Angela's teaching. Habitat is part of the Grade 4 curriculum. She has successfully applied through Ducks Unlimited Canada's Project Webfoot for funding for field trips to a local wetland (such as the Bill Mason Outdoor Education Centre). They have also had field trips to the Bonnechere Caves. In

addition to all of this, Angela leads informal lunchtime field trips for interested students to a nearby natural area, to learn about and develop an appreciation for nature. One day they may focus on birds, the next day on insects, and the third on plants. She applied for and received funding to organize a field trip for The Dragonflies club for a day to learn about bird banding at Innis Point Bird Observatory. The children were excited to each hold a chickadee or nut-hatch. On breaks they played nature games in the field, and went on a nature hike. Angela teams up with her husband Jeff Skevington to help him lead "kid friendly" field trips for The Ottawa Field-Naturalists' Club as well as for other nature clubs in the Ottawa Valley. Angela assisted Jeff and colleagues in hosting a well-attended Bug Day held at the Fletcher Wildlife Garden last year. Angela's efforts are recognized and appreciated, as evidenced by fellow teacher Donna Christie who said: "I feel honoured to work with Angela and know that she has made a positive impact on her students and our school She is a scientifically-oriented, dedicated, hard-working educator." The OFNC is delighted to present the Mary Stuart Education Award for 2013 to Angela in recognition of her success in raising awareness of environmental stewardship and respect for nature at her school and more broadly.] Address: not stated

15157. Achterkamp, B.; van de Hatert, R.J.W. (2015): Common dragonflies as indicators for water habitats: a start on a practical approach. *Brachytron* 17(2): 87-99. (in Dutch, with English summary) ["Dragonflies are widely used as indicator species for water and habitat quality, especially rare species with very specific habitat requirements. However, in many waters only common species occur that have less strict habitat requirements. Nevertheless, even from these common species, indications can be derived about water and habitat quality. During research for water boards in the Netherlands, the authors have developed a system of ecological groups. The groups were developed on the basis of the larval habitat (mainly based on literature) and behaviour of the adults (mainly based on field experience). Each group is indicative for the habitat quality in a certain zone, or of a certain aspect like oxygen concentration. The 'riparian' group consists of species that prefer riparian vegetation with emergent plants in combination with submerged and float-ingleaved plants. The 'water' group seeks the open water surface without emergent vegetation; submerged and float-ingleaved plants can be present and improve habitat quality. The 'shallow' group is comprised of species that can reproduce in eutrophic waters only when there is a broad zone of shallow water with a open vegetation structure that quickly heats in the sun. The groups 'oxygen' and 'pioneer' are self-explanatory. The groups have been developed for relatively eutrophic, stagnant or slow flowing waters in the eastern and southern part of the Netherlands. Comparable classifications in international literature show that the groups are wider applicable. Of course, such grouping always has to be adapted to regional dragonfly faunas, other water types or specific ecological questions. We hope that

these groups will inspire other observers to look closer at the relations between dragonflies and their (micro-) habitat." (Authors)] Address: Achterkamp, B., Bureau Waardenburg, postbus 365, 4100 AJ Culemborg, The Netherlands. E-mail: b.achterkamp@buwa.nl

15161. Adu, B.W.; Ogbogu, S.S.; Kemabonta, K.A. (2015): Dragonflies and damselflies (Insecta: Odonata) as tools for habitat quality assessment and monitoring. *FUTA Journal of Research in Sciences* 11(1): 36-45. (in English) ["Odonata of Obafemi Awolowo University Ile-Ife, Nigeria were assessed for the purpose of determining the habitat quality of Odonata community in the campus. Adult Odonata were sampled at four study sites at the campus. The study sites are Opa Reservoir spillway stream: OR, Health Sciences: HS, Biological Garden: BG, and Staff Quarters: SQ. A total of 195 individuals comprising of 36 species in six families (Aeshnidae, Libellulidae, Calopterygidae, Chlorocyphidae, Coenagrionidae and Platycnemididae) were sampled at the campus (Identification by K.D Dijkstra). Similarity test on the odonate community structure at the four study sites was conducted using Soerensen's quotient. OR/BG and OR/SQ were similar, while the other paired study sites (BG/SQ, OR/HS, HS/BG and HS/SQ) were dissimilar. Diversity indices results have Shannon Wiener (H') value ranging between 2.20 - 3.05, Simpson value ranging between 0.86 - 0.95 and Margalef value ranging between 3.39 - 5.8 for the four sites. BG was the richest study site with the highest values (Shannon Wiener: 3.05, Simpson: 0.95 Margalef: 5.8 and evenness was 0.92), followed by OR (Shannon Wiener: 2.96, Simpson: 0.94 Margalef: 5.41 and evenness was 0.81). The forest environments of Obafemi Awolowo University appeared been depleted yet possessed the habitat quality that sustained some species of Odonata. Nevertheless BG and OR have proven to possess the best community structure for the existence of Odonata fauna in the campus." (Authors)] Address: Adu, B.W., Dept Biol. Sci., Ondo State University of Science & Technology, Okitipupa, Ondo State Nigeria. E-mail: williamsadubabs@yahoo.com

15162. Adu, B.W.; Akindede, E.O.; Obadofin, A.A. (2015): Composition and distribution of dragonflies and damselflies (Insecta: Odonata) in Iloyin Forest, Akure, Southwestern Nigeria. *Ethiopian Journal of Environmental Studies and Management* 8(5): 517-529. (in English) ["Odonate fauna of Iloyin Forest was studied from October to December 2009 to have an overview of the species composition and distribution with the threat of deforestation in the area. Adult species were collected once a week using a sweep net throughout the period of the study from three study sites (denoted

as I, II and III) with varying levels of anthropogenic disturbance. A total of 76 species belonging to eight families were recorded in the forest. The two most abundant families in the forest were the Libellulidae and Coenagrionidae. *Palpolpeura portia*, *P. lucia* and *Congothemis dubia* were the dominant species of Libellulidae, while *Pseudagrion kersteni* was the dominant coenagrionid. Some species of Odonata usually associated with shaded forests were encountered in two of the study sites. The highest diversity and evenness indices were recorded at Site I, followed by Site II and the least recorded at Site III. Although shade-loving species recorded in the study area was an indication of its richness in forest Odonata, some may have however become locally endangered or extinct as a result of deforestation. A check in the rate of deforestation could preserve the few forest (endangered) species and restore the locally extinct ones that changed habitats." 15165. Alvarez-Covelli, C.; Alvarez-Covelli, M.A.; Palacino-Rodríguez, F. (2015): Abdomen or wings? Comparing two body places for marking in *Mesamphiagrion laterale* (Odonata: Coenagrionidae). *Odonatologica* 44(3): 343-348. (in English) ["To assess a marking technique that avoids alteration of wing aspect and thereby reduces the effect of marking on the organisms' behaviour, adult individuals of *Mesamphiagrion laterale* (Selys, 1876) were marked on two body regions and their probability of resighting (PR) was estimated. Marks were placed as irregular spots of turquoise, magenta, lime, and orange colour. The PR of wing-marked individuals and abdomen-marked individuals was compared. A total PR of 80% was detected. PR was higher

when the marks were placed on the abdomen (PR=0.72) than on the wings (PR=0.62), but no significance was found between these recapture rates ($\chi^2=0.413$). This exercise should be implemented in other odonate species to see the widespread nature of our results." 15166. Ameka, C.M. (2015): Effects of insect growth regulator pyriproxyfen on dragonfly nymphs as predators of anopheles mosquitoes at Mahanga, Vihiga County, Kenya. M.Sc. thesis, Agricultural Entomology, School of Pure and Applied Sciences of Kenyatta University: XII + 56 pp. (in English) ["Malaria in sub-Saharan Africa is transmitted mainly by *Anopheles gambiae* Complex mosquitoes. One way of controlling these vectors is by targeting their aquatic stages, which is anticipated to cause significant reduction in adult vectors, hence in malaria transmission. Use of insect growth regulator, Pyriproxyfen, is one potential way of controlling malaria vectors. This study set out to determine the nymphocidal activity of Pyriproxyfen on non-target aquatic dragonfly nymphs during its application to control malaria vectors in western Kenya highlands. In this study, validation of dragonfly nymphs as predators of malaria vectors was done and impact of Pyriproxyfen on these nymphs was determined in Mahanga Village of Vihiga County in western Kenya highlands. One hundred dragonfly nymphs were exposed to third instar larvae of *A. gambiae* to determine their predation efficiency by counting the number of larvae remaining after predation. Eighty 5th instar dragonfly nymphs were exposed to Pyriproxyfen (Sumilarv0.5 G) at concentrations of 0.01ppm, 0.05ppm, 0.1ppm, and filtered tap water as control. The experiment was replicated four times and repeated in ten rounds in the laboratory. Observations were made at 24 hour intervals and data collected on mortality of dragonfly nymphs. One gram of Pyriproxyfen was applied in the 10 randomly selected mosquito breeding habitats at Mahanga once every month. Control experiments in *An. gambiae* breeding habitats were done at Muluhoro study site located 10Km away from Mahanga to avoid contamination by Pyriproxyfen (Sumilarv 0.5G). Percentage predation of 95% was obtained in 24 hours of exposure of *An. gambiae* larvae indicating that the dragonfly nymphs are efficient predators of *A. gambiae*. The insect growth regulator Pyriproxyfen (Sumilarv 0.5G) had nymphocidal activity on the dragonfly nymphs at a concentration of 0.05ppm and 0.1ppm in laboratory assays. Abundance of dragonfly nymphs in *An. gambiae* breeding habitat was determined by comparing the abundance of dragonfly nymphs in the intervention sites at Mahanga and non intervention site at Muluhoro. The results indicated that the dragonfly nymphs were present in both sites over the 11month period. Analysis using Generalized Estimation Equations (GEE) showed that the abundance of dragonfly nymphs was significantly different ($p<0.01$) and there was insignificant nymphocidal activity of Pyriproxyfen (Sumilarv 0.5G) on the dragonfly

nymphs in both the intervention and non intervention ($p>0.05$). The findings of this study have shown that Pyriproxyfen (Sumilarv 0.5G) had insignificant nymphocidal activity on dragonfly nymph when used as a larvicide at lower concentrations of 0.05ppm ($p>0.05$). The study recommends that dragonfly nymphs should be included in mosquito control programs as they are predators of mosquito larvae. Additionally, Pyriproxyfen should not be used at higher dosages of more than 0.05ppm as it affects non target dragonfly nymphs." 15168. Andrew, R.J. (2015): Observations on a gynochromatic (?) male of the dragonfly, *Rhodothemis rufa* (Rambur, 1842) (Odonata: Libellulidae). Journal of Threatened Taxa 7(3): 7007-7010. (in English) ["*R. rufa* exhibits a conspicuous sexual dimorphism in its body colour. The mature male is characterized by the homogenous striking brilliant red body while the mature female is dull brown with a prominent mid-dorsal light yellow streak running from the top of the head through the thorax and down to the fifth segment of the abdomen. The sexes can easily be identified from quite a long distance. On 7 November 2012, we observed the unusual sight of a female *R. rufa* chasing another female and forming a tandem link which was followed by copulation. This peculiar reproductive behaviour instigated us to net the specimen. On inspection we found that although it appeared a female, it had well developed external male genitalia in the form of the secondary copulatory apparatus on the venter of the second and third abdomen, a pair of coxites on the ninth abdominal tergum and an additional infra anal appendage at the terminal tip of the abdomen. The testes contained a large number of lobules filled with mature spermatozoa, and the vasa differentia also contained mature sperms. The sperm sac was filled with sperms embedded in seminal fluid. Observations indicate that this could be a rare case of a gynochromatic male of *R. rufa* which has retained the colour patterning of the female even after sexual maturity and concomitantly exhibiting active sexual behaviour, although the case of it being a subadult male which has yet to attain its typical red coloration cannot be ruled

out." (Author)] Address: Andrew, R.J., Post Graduate Department of Zoology, Hislop College, Nagpur, Maharashtra 440001, India. E-mail: rajuandrew@yahoo.com

15169. Appel, E.; Heepe, L.; Lin, C.-P.; Gorb, S.N. (2015): Ultrastructure of dragonfly wing veins: composite structure of fibrous material supplemented by resilin. *Journal of Anatomy* 227(4): 561-582. (in English) ["Dragonflies count among the most skilful of the flying insects. Their exceptional aerodynamic performance has been the subject of various studies. Morphological and kinematic investigations have showed that dragonfly wings, though being rather stiff, are able to undergo passive deformation during flight, thereby improving the aerodynamic performance. Resilin, a rubber-like protein, has been suggested to be a key component in insect wing flexibility and deformation in response to aerodynamic loads, and has been reported in various arthropod locomotor systems. It has already been found in wing vein joints, connecting longitudinal veins to cross veins, and was shown to endow the dragonfly wing with chordwise flexibility, thereby most likely influencing the dragonfly's flight performance. The present study revealed that resilin is not only present in wing vein joints, but also in the internal cuticle layers of veins in wings of *Sympetrum vulgatum* (SV) and *Matrona basilaris basilaris* (MBB). Combined with other structural features of wing veins, such as number and thickness of cuticle layers, material composition, and cross-sectional shape, resilin most probably has an effect on the vein's material properties and the degree of elastic deformations. In order to elucidate the wing vein ultrastructure and the exact localisation of resilin in the internal layers of the vein cuticle, the approaches of bright-field light microscopy, wide-field fluorescence microscopy, confocal laser-scanning microscopy, scanning electron microscopy and transmission electron microscopy were combined. Wing veins were shown to consist of up to six different cuticle layers and a single row of underlying epidermal cells. In wing veins of MBB, the latter are densely packed with light-scattering spheres, previously shown to produce structural colours in the form of quasicrystalline arrays. Longitudinal and cross veins differ significantly in relative thickness of exo- and endocuticle, with cross veins showing a much thicker exocuticle. The presence of resilin in the unsclerotised endocuticle suggests its contribution to an increased energy storage and material flexibility, thus to the prevention of vein damage. This is especially important in the highly stressed longitudinal veins, which have much lower possibility to yield to applied loads with the aid of vein joints, as the cross veins do. These results may be relevant not only for biologists, but may also contribute to optimise the design of micro-air vehicles." 15170. Arambourou, H.; Stoks, R. (2015): Combined effects of larval exposure to a heat wave and chlorpyrifos in northern and southern populations of the damselfly

Ischnura elegans. *Chemosphere* 128: 148-154. (in English) ["Highlights: •Damselfly larvae were sequentially exposed to a heat wave and chlorpyrifos. •Surprisingly, the heat wave positively affected fat storage and immune function. •Chlorpyrifos had strong negative effects on survival, growth and fat storage. •The AChE inhibition by chlorpyrifos was magnified by the heat wave. •Delayed effects of heat waves may make damselflies more vulnerable to pesticides. Abstract: Heat waves are generally associated with an increased energy consumption and could thus increase the vulnerability to subsequent pesticide exposure. We investigated the combined effect of a heat wave and subsequent exposure to the pesticide chlorpyrifos in *Ischnura elegans* damselfly larvae. To assess local thermal adaptation to heat waves, we applied these combined stressors on replicated low- and high-latitude populations in Europe. Unexpectedly, we observed positive sublethal effects of the heat wave: fat content and phenoloxidase activity increased. Chlorpyrifos had strong negative effects on survival, growth rate, and fat content, while phenoloxidase activity increased; these effects between latitudes were found similar. We found little indication of a higher ability to withstand a heat wave in southern larvae. We did detect a synergistic negative effect on AChE activity. This result highlights the importance of considering delayed effects of extreme temperature events when assessing the impact of pesticides under climate change." 15171. Arambourou, H.; Stoks, R. (2015): Warmer winters modulate life history and energy storage but do not affect sensitivity to a widespread pesticide in an aquatic insect. *Aquatic Toxicology* 167: 38-45. (in English) ["Highlights: • Damselfly larvae were sequentially exposed to winter warming and chlorpyrifos. • Low and high-latitude European populations of a damselfly were studied. • Damselfly larvae, especially from low latitude, benefited from winter warming. • Chlorpyrifos exposure negatively affected life-history and biochemical markers. • Pesticide effects were not magnified by winter warming. Despite the increased attention for the effects of pesticides under global warming no studies tested how winter warming affects subsequent sensitivity to pesticides. Winter warming is expected to cause delayed negative effects when it increases metabolic rates and thereby depletes energy reserves. Using a common-garden experiment, we investigated the combined effect of a 4 °C increase in winter temperature and subsequent exposure to chlorpyrifos in the aquatic larvae of replicated low- and high-latitude European populations of the damselfly *Ischnura elegans*. The warmer winter (8 °C) resulted in a higher winter survival and higher growth rates compared to the cold winter (4 °C) commonly experienced by European high-latitude populations. Low-latitude populations were better at coping with the warmer winter, indicating thermal adaptation to the local winter temperatures. Subsequent chlorpyrifos exposure at 20 °C induced strong negative effects on survival, growth rate, lipid content and acetylcholinesterase activity

while phenoloxidase activity increased. These pesticide effects were not affected by winter warming. Our results suggest that for species where winter warming has positive effects on life history, no delayed effects on the sensitivity to subsequent pesticide exposure should be expected." 15172. Archana, A.; Sharad, S.; Pratibha, A. (2015): Seasonal biological water quality assessment of River Kshipra using benthic macro-invertebrates. *International Journal of Research - Granthaalayah* 3(9): 7 pp. (in English) [India "The water quality of River Kshipra in stretch of 195 km was studied for water quality status using benthic macro invertebrates for all three seasons' monsoon, winter and summer. The River water quality is subject to severe domestic and industrial pollution at compete stretch of River. In the present investigation a total of 13 Orders of macrobenthic fauna i.e. Ephemeroptera, Trichoptera, Placoptera, Coleoptera, Hemiptera, Odonata, Crustacea, Diptera, Pulmonata, Operculata, Pulmonata, Oligochaeta and Hirudinea belong to 3 Phylum's Arthropoda, Mollusca and Annelida were reported. Arthropoda was the most dominant group in all seasons. On seasonal comparison of benthic fauna is observe that abundance were decreasing order were, Winter > Monsoon > summer. To monitor the water quality samples from two years (2010-12) from different stations were collected monthly. The works highlighted the condition of the River water in various seasons with respect of the seasonal abundance of the benthic macro-invertebrates organisms mentioned above. Odonata- The presence of these animals indicates input of little organic pollution in the slow moving or standing clean waters. They can be observed around water bodies, nymph of dragons is robust while damsel is slender with distinct head, thorax and abdomen. Order Odonata represented by Family Coenagriidae, Corduliidae and Gomphidae. The seasonal percentage dominance of order Odonata in monsoon (5.37%), followed by (2.70%) in winter and in summer completely absent. This observation clearly indicate highly polluted status in summer because Odonata nymph were found in only fresh water there is abundance of oxygen and unpolluted water. Lonkar and Kedar, (2014) also reported similar observations." (Authors)] Address: Archana, A., School of studies in Zoology and Biotechnology, Vikram University, Ujjain (M.P.), India

15173. Arimoro, F.O.; Odume, O.F.; Uhunoma, S.I.; Edegbene, A.O. (2015): Anthropogenic impact on water chemistry and benthic macroinvertebrate associated changes in a southern Nigeria stream. *Environmental Monitoring and Assessment* 187: 1-14. (in English) ["The Ogba River in southern Nigeria is an important water resource for its riparian communities. This study evaluates impact of anthropogenic influences on the Ogba River using water chemistry and macroinvertebrate data sets obtained over a period of 6 months between January and June 2012. Four stations, stations 1-4, characterised by various human activities were chosen along the river. Organic wastes from domestic

and industrial sources were the major point sources of pollutants. Station 2 where the municipal wastewater drains into the river had elevated values of flow velocity, BOD5, sulphate, phosphate, nitrate and sodium. Based on the canonical correspondence analysis (CCA), 5-day biochemical oxygen demand (BOD5), sulphate, nitrate and phosphate were the main factors that help to shape the macroinvertebrate assemblage structure of the Ogba River. Macroinvertebrates clustered strongly by stations than by seasons indicating that water quality differences between the stations were responsible for the observed differences in the biotic assemblage. The preponderance of naidid oligochaetes, baetid nymphs and certain tolerant dipteran taxa including chironomids and ceratopogonids at all four stations was an indication that the entire water body was stressed. The odonates were the single most abundant taxa; their dominance could be attributed to the vegetative nature of the stream, favouring odonate colonisation. Overall, the responses of macroinvertebrates to stress were reflected by the different assemblage structures recorded at the four study stations. Substrate and microhabitat obliteration and poor water quality appeared to be the factors responsible for the observed assemblage structure in the Ogba River." 15176. Assandri, G. (2015): L'odonatofauna (Insecta Odonata) delle basse Valli di Susa, Sangone e di Lanzo (Torino, Italia). *Memorie della Società Entomologica Italiana* 92(1-2): 39-75. (in Italian, with English summary) ["The objective of this paper is to fill the knowledge gaps on Odonate fauna of the low Susa, Sangone and Lanzo valleys (Turin, NW Italy), an area for which there was limited prior knowledge. The available information (153 records) have been reviewed and updated at the same time through an in-depth exploration of the territory (between 2009 and 2013), which involved 137 field surveys on 34 sampling sites of diverse nature (28 lentic and 6 lotic), which produced further 913 records. Overall in the study area were found a total of 45 species, with reproduction ascertained for 37 of them. The occurrence of 3 species recorded in the past was not confirmed and 8 are new (compared to the 2007 regional atlas). Some rich and diverse communities were found and also some species considered rare in north-Western Italy (*Boyeria irene*, *Onychogomphus uncatatus*, *Cordulegaster bidentata* and *Somatochlora flavomaculata*). Statistically, in the non protected sites there are no less species than those of protected sites (Regional Parks and SPAs). This underline an inadequacy of protected areas network in order to pursue the conservation of this taxon in the studied region, already subjected to a strong anthropogenic pressures that is threatening some sites of great value. It is finally given a qualitative and quantitative indication of the species' flight periods." 15177. Ball, O.-P.; Pohe, S.R.; Winterbourn, M.J. (2015): Littoral macroinvertebrate communities of dune lakes in the far north of New Zealand. *New Zealand Journal of Marine and Freshwater Research* 49(2): 192-204. (in English) ["The littoral macroinvertebrate faunas of 17 dune lakes on the Aupouri Peninsula in northern New Zealand were examined. Land cover of individual catchments was principally sand dunes and scrub, plantation forest, pasture, or a mixture of plantation forest and pasture. Sampling was concentrated in the sedge beds, submerged macrophytes and surface sediment layers of the littoral zone. Sixty-eight invertebrate taxa were recorded, 11–30 per lake. Relative abundance of major faunal groups differed considerably among lakes but a core group of common species was found in three quarters of them. Neither community composition, nor various measures of species richness were related significantly to catchment land cover classes. A feature of the lake fauna was the occurrence of three introduced species of Gastropoda and eight self-introduced insect species, including five dragonflies. One of the latter, *Hemicordulia australiae*, was found in all lakes and made up 3% of all invertebrates collected." 15178. Baran, A. (2015): Blending Traditional Fish Culture with Non-Traditional Species and Methods at Genoa NFH. 145th Annual Meeting of the American Fisheries Society, August 16-20th August: (in English) [Verbatim: Genoa NFH was established over 80 years ago by the Upper Mississippi River Fish and Wildlife Act. The mission of the hatchery has changed from providing sport fish for area waters to a conservation hatchery concerned with recovery of endangered aquatic species. The hatchery works with over 35 aquatic species including fish, freshwater mussels, salamanders and now an endangered dragonfly. These programs have required different approaches to methods and equipment used in fish culture. Genoa has constructed several mobile rearing units, one for the mussel program, two for the sturgeon program and will begin construction in 2015 on a unit for the Hine's Emerald Dragonfly (*Somatochlora hineana*). These mobile units allow the station to work in the native environments of the different species, using source water from the natal rivers of lake sturgeon or the nutrient rich water of the Mississippi River for the mussels. The design of the mobile units also allows the hatchery to bring wild species on station without compromising the disease status by using UV disinfection on both the incoming and effluent water. These units can be deployed at the hatchery to quarantine potential mussel host fish, future brood fish as well as the new dragonfly species.] Address: Baran, Angela, DOI USFWS Genoa National Fish Hatchery, Genoa, WI, USA

15179. Barry, M.J. (2015): Effects of resource distribution on the cost of predator avoidance behaviour in tadpoles. *Hydrobiologia* 758: 99-105. (in English) ["Tadpoles reduce activity and increase hiding in the presence of dragonfly larvae. Several studies demonstrate that tadpoles showing this behaviour have slower growth, however, other studies have found no effect or even positive growth in tadpoles exposed to predators. A recent study demonstrated that swimming is an energetically expensive activity for *Bufo arabicus* tadpoles. Therefore, if food resources are abundant close to refuges, reduced activity may be an advantage and could offset the cost of reduced foraging. I tested this hypothesis by growing *B. arabicus* tadpoles with food provided either near or away from shelters, in the presence or absence of caged dragonfly larvae (*Anax imperator*). In the presence of dragonfly larvae, tadpoles provided with food close to shelters were significantly larger than those with food further away. Control tadpoles under both food treatments were intermediate in size, although not statistically different from the predator + near food tadpoles. The results indicate that access to resources is the main determinant of growth in *B. arabicus* tadpoles and that the energetic cost of swimming is a secondary factor." 15183. Bazzanti, M. (2015): Pond macroinvertebrates of the Presidential Estate of Castelporziano (Rome): a review of ecological aspects and selecting indicator taxa for conservation. *Rendiconti Lincei* 26, Supplement 3: 337-343. (in English) ["Macroinvertebrates of 49 (27 temporary and 22 permanent) ponds located in the Presidential Estate of Castelporziano (Rome) were studied from 1989 to 2004 to investigate their community ecology and to provide a first estimation of their conservation value. More than 300 taxa (about 70 % identified to species) were collected. The main environmental factors influencing the number of species in the study ponds were hydroperiod length, depth, surface area, dissolved oxygen concentration and macrophyte spe-

cies richness and abundances. Permanent biotopes generally hosted higher number of taxa than temporary ones. Some taxa were exclusive or more abundant in a pond type. Functional organization (functional feeding groups, habits and resistance to desiccation) of the community appeared similar in the two pond types but differed among mesohabitats. Up to date, about 62 % of the taxa collected have an unknown status with respect to their distribution in Italy (common, rare, threatened and vulnerable). We identified 50 target species with peculiar ecological requirements and/or geographical distribution to promote effective practical basis for pond conservation in Italy. The distribution of rare, vulnerable or threatened species within the ponds studied suggests that the two pond types and all mesohabitats therein should be considered for the sampling procedure to obtain a correct evaluation of pond conservation." (Author) 19 odonate species had been recorded, but no species details are given.] Address: Bazzanti, M., Department of Environmental Biology, "Sapienza" University of Rome, Viale dell'Università 32, 00185, Rome, Italy. 15184. Beard, J.L. (2015): Perch selection by male dragonflies (Odonata, Anisoptera) related to competitive ability and species composition. Ph.D. thesis, Department of Biological Sciences, Old Dominion University, Norfolk: XII, 67 pp. (in English) ["Males of many species of dragonflies (Odonata, Anisoptera) establish territories in aquatic habitats where they compete with other males for access to food and females. Territorial males typically perch on emergent vegetation and chase rival males who intrude into their territories. This dissertation research examined the role of male size in perch height selection, position on the perch, and competitive ability. Four hypotheses were tested: 1) Dragonfly species would vary by size and that territorial species would show sexual size dimorphism (SSD), 2) Perch height selection would be related to dragonfly size, 3) Position on the perch would be related to male size, with larger males selecting perch tops and smaller inferior competitors choosing the sides of perches, and 4) Intraspecific competition would be more important than interspecific competition. Research was conducted at four lakes in southeastern Virginia from 2011-2014. For size measurements, male and female dragonflies (*Brachymeria grandidens*, *Celithemis epina*, *Erythrodiplax simplicicollis*, *Libellula incesta*, *L. needhami*, *L. vibrans*, *Pachydiplax longipennis*, *Plathemis lydia*, *Perithemis tenera*) were captured and measured for total body length, abdomen length, cerci length, forewing length and width, hindwing length and width and fresh mass. For perching experiments, alternating short (30cm above waterline) and tall (90cm above waterline) bamboo perches were placed in two rows, 0.5m and 2.0m from the shore. Any dragonflies that alighted on perches were recorded for species, gender, perch position and length of occupancy. Any interactions with conspecific or heterospecific dragonflies were recorded. Results showed that dragonfly males varied significantly among species in all parameters measured, and SSD was found for some parameters for some of the species. In particular, females of several species had

greater forewing and hindwing widths than males, perhaps related to selection for energy conservation in females. There was no association between dragonfly size and perch height selection. Four species frequently perched on the sides rather than the tops of perches, and these species tended to be poor competitors who lost more contests than they won. The number of intraspecific and interspecific contests did not differ for any species. Neither dragonfly size nor residency on a perch influenced contest outcomes. Overall, these results revealed that dragonfly community interactions were dynamic and did not follow simple rules." 15185. Beatty, C.D.; Andrés, J.A.; Sherratt, T.N. (2015): Conspicuous coloration in males of the damselfly *Nehalennia irene* (Zygoptera: Coenagrionidae): Do males signal their unprofitability to other males? *PLoS One*. 2015 Nov 20;10(11):e0142684. doi: 10.1371/journal.pone.0142684. eCollection 2015.: 13 pp. (in English) ["In damselflies, sexual colour dimorphism is commonly explained as a consequence of selection on traits that increase male attractiveness to females. However, while many species in the Coenagrionidae are sexually dimorphic, the males do not engage in displays, and male competition for mates resembles a "scramble". An alternative explanation for the sexual differences in coloration within these species is that sexual dimorphism has evolved as a sex-related warning signal, with males signalling their unprofitability as mates to other males, thereby avoiding harassment from conspecifics. We evaluated an underlying assumption of the theory that male-male harassment rate is influenced by colour by comparing harassment of males of the species *Nehalennia irene* that had been painted to make them appear: (i) similar to an unaltered male (blue), (ii) different from a male (orange) and (iii) more similar to a female (black). When caged together we found that blue-painted males experienced significantly lower harassment than black-painted males. When unpainted males were caged with each type of painted male we found that blue-painted males and the unpainted males housed in the same cages experienced lower rates of harassment than males housed in cages where some males were painted black, suggesting that a single, reliable signal of unprofitability may benefit the individuals that carry it. While our results do not in themselves demonstrate that sexual colour dimorphism originally evolved as an intraspecific warning signal, they do show that harassment is influenced by coloration, and that such selection could conceivably maintain male coloration as a warning signal." 15186. Bellenguier, L.; Delpon, G. (2015): Sur la détection de *Somatochlora arctica* et l'estimation de ses populations: l'exemple de la tourbière de la Pignole dans le Cantal (Odonata: Corduliidae). *Martinia* 31(1): 35-46. (in French, with English summary) ["Surveys conducted in 2013 on the Pignole peat bog (Cantal department, France) proved the

settlement of a strong population of *Somatochlora arctica*. The well-known species discretion was confirmed, emphasising the need to collect and number the exuviae during the emergence period. The ratio of the number of exuviae found to the number of imagoes observed on the wing and at emergence was ca 18. This estimate is expected to vary with space and should be refined by similar numerations in other localities. The discretion of this species raises the question of its detectability and of the changes in the numbers of its records over time. It appears that the species was obviously largely overlooked before 1980 due to too rare field works and that only intensive field surveys during the last three decades allowed to assess correctly its genuine status in the region." 15188. Bennett, A.M.; Murray, D.L. (2015): Carryover effects of phenotypic plasticity: Embryonic environment and larval response to predation risk in wood (*Lithobates sylvaticus*) and Northern leopard (*Lithobates pipiens*) frogs. *Canadian Journal of Zoology* 93(11): 867-877. (in English) ["Limitations of phenotypic plasticity affect the success of individuals and populations in changing environments. We assessed the plasticity-history limitation on predator-induced defenses in anurans (wood frogs: *Lithobates sylvaticus* (LeConte, 1825); Northern leopard frogs: *L. pipiens* (Schreber, 1782)), predicting that plastic responses to predation risk by dragonfly larvae (*Aeshna* spp.) in the embryonic environment would limit the defensive response to predators in the larval environment. Predator-conditioned wood frog embryos increased relative tail depth in response to those same cues as larvae, whereas predator-naïve tadpoles did not. However, no carryover effect was noted in the behavioural response of wood frog tadpoles to predation risk. Predator-naïve Northern leopard frog tadpoles increased relative tail depth in response to predation risk in the larval environment. Predator-conditioned leopard frog embryos hatched with, and maintained, a marginal increase in tail depth as larvae in the absence of predation risk. Predator-conditioned leopard frog embryos exposed to predation risk as larvae showed no morphological response. While we find no strong support for the plasticity-history limitation per se, carryover effects across embryonic and larval life-history stages were noted in both wood and leopard frogs, suggesting that predation risk early in ontogeny can influence the outcome of future interactions with predators." 15189. Bernard, B.; Daraz, B. (2015): *Cordulegaster heros* and *Somatochlora meridionalis* in Ukraine: solving the zoogeographical puzzle at their northern range limits (Odonata: Cordulegastridae, Corduliidae). *Odonatologica* 44(3): 255-278. (in Dragonfly, Anisoptera, Balkan fauna, Eastern Europe, zoogeography, habitat selection) ["The first records of *C. heros* and *S. meridionalis* in Ukraine completed their distribution picture, thereby allowing the zoogeography of Balkan Odonata species at their northern range limit in Eastern Europe to be better understood. Five localities of *C. heros* in the Khotyn and Chernivtsi Uplands showed the eastern colonisation route to have proceeded north through the eastern Subcarpathians and adjacent hilly areas in Romania and southern Ukraine. A habitat and zoogeographical analysis mostly solved the *Cordulegaster*-puzzle in Ukraine and drew a picture of a northern *C. boltonii*-zone divided from a southern *C. heros*-zone by the extensive Podolian Upland. The population of *S. meridionalis* found in the extreme southwestern Ukraine completed the northernmost range limit in Eastern Europe between the known Slovakian and Romanian localities. It occurs in the Transcarpathian Lowland, i.e., the northernmost part of the Great Hungarian Plain in the direct foreground of the Carpathian foothills. Thus, it perfectly follows the species distribution pattern largely based on an extensive border zone of great basins and low foothills of the adjacent mountain ranges of the Carpathians and Alps. The situation and habitat of Ukrainian and eastern Slovakian localities suggest the Tisa River system as the main colonisation route of *S. meridionalis* for Central and Eastern Europe. Clear differences in the population sizes between streams suggested the optimal, acceptable, and marginal habitats of *C. heros*, which differed in the grain size of the bottom sediments, the stream morphology, and water current. *Somatochlora meridionalis* occurred in a several-metre-broad slow flowing and largely shaded canal-like river where specific habitat conditions were responsible for the concentration of species activity near the levee and pipe culvert." 15190. Berquier, C. (2015): Étude écologique et patrimoniale du peuplement des odonates de Corse appliquée à la conservation des espèces et des zones humides à enjeux. Ph.D thesis, Université de Corse -Pascal Paoli, Ecole Doctorale "Environnement et société" UMR CNRS 6134 (SPE): 310 pp. (in French, with English summary) ["Corsica is home to a great diversity of wetland subject to anthropogenic pressures and threats which have continued to grow and diversify in recent decades. The conservation of these environments with high heritage value and of the original Odonata community that develops in it, today represents significant environmental and societal challenges in order to preserve essential ecological services provided by these key elements of aquatic and terrestrial ecosystems. The applied research project developed as part of this thesis is focused on improving the knowledge available on the Corsi-

can dragonfly's community, to propose concrete conservation and management measures for this group and its main insular natural habitats. In this objective, the first part of this work has sought to fill principal knowledge gaps identified by previous studies on the situation of listed species, including by greatly intensifying exploration effort at the regional level. The special features, distribution, habitat requirements and ecological of many dragonflies growing in Corsica have been described with great precision. The information available on some taxa with high heritage value increased as illustrated by the comprehensive definition of eco-bio-geographical situation of *Chalcolestes parvidens*. The second part of this work has sought to evaluate and compare the effectiveness of the main sampling methods commonly used for the study of dragonfly's populations. In this context, the information collected on the spatial organization and dynamics of the populations studied were especially used to propose appropriate methods for evaluation and monitoring the species to high conservation issue to main managers of natural areas of the island (County Councils, PNRC, municipalities ...), including the emblematic and threatened *Lestes macrostigma*. The third part of this work is devoted to the development of tools for monitoring the quality of the main Odonata habitats. It lead to the development of a new biological index adapted to assess the ecological status of Corsican rivers: "Odonata Community Index - Corsica '(OCIC). This innovative tool, based on the study of characteristics of Odonata community of watercourses, was particularly effective during its confrontation with other biological indicators currently used on the island. The OCIC index today appear clearly as an alternative solution to improve the efficiency of the ecological quality assessment system of the Corsican rivers, given the representativeness vulnerabilities which have been highlighted by the tests performed. The final part of this thesis, based on heritage and environmental assessments of the insular dragonfly's community made with all the information produced, ended with the development and the proposal of several regional conservation devices whose implementation is encouraged by the state services: a first regional actions plan, a first red list of threatened species and an updated list of species determinative for natural areas of ecological, flora and fauna interest. These important features are intended to contribute to improve the overall state of conservation of Corsican dragonflies and main wetlands that support them. They should enable the implementation of truly operational management actions and ensure better consideration of the main regional conservation and valuation issues identified. In the end, the thesis work that increased more than triple the previously available data on dragonflies of Corsica, will provide a new framework to develop the insular odonatology." ford, R.J.; Ivanova, E.P. (2015): Antibacterial titanium nano-patterned arrays inspired by dragonfly wings. *Scientific Reports* | 5:16817 | DOI: 10.1038/srep16817: 12 pp. (in English) ["Titanium and its alloys remain the most popular choice as a medical implant material because of its desirable properties. The successful osseointegration of titanium implants is, however, adversely affected by the presence of bacterial biofilms that can form on the surface, and hence methods for preventing the formation of surface biofilms have been the subject of intensive research over the past few years. In this study, we report the response of bacteria and primary human fibroblasts to the antibacterial nanoarrays fabricated on titanium surfaces using a simple hydrothermal etching process. These fabricated titanium surfaces were shown to possess selective bactericidal activity, eliminating almost 50% of *Pseudomonas aeruginosa* cells and about 20% of the *Staphylococcus aureus* cells coming into contact with the surface. These nano-patterned surfaces were also shown to enhance the aligned attachment behaviour and proliferation of primary human fibroblasts over 10 days of growth. These antibacterial surfaces, which are capable of exhibiting differential responses to bacterial and eukaryotic cells, represent surfaces that have excellent prospects for biomedical applications." 15192. Bhowmik, A.K.; Schäfer, R.B. (2015): Large scale relationship between aquatic insect traits and climate. *PLoS ONE* 10(6): e0130025. doi:10.1371/journal.pone.0130025: 21 pp. (in English) ["Climate is the predominant environmental driver of freshwater assemblage pattern on large spatial scales, and traits of freshwater organisms have shown considerable potential to identify impacts of climate change. Although several studies suggest traits that may indicate vulnerability to climate change, the empirical relationship between freshwater assemblage trait composition and climate has been rarely examined on large scales. We compared the responses of the assumed climate-associated traits from six grouping features to 35 bioclimatic indices (~18 km resolution) for five insect orders (Diptera, Ephemeroptera, Odonata, Plecoptera and Trichoptera), evaluated their potential for changing distribution pattern under future climate change and identified the most influential bioclimatic indices. The data comprised 782 species and 395 genera sampled in 4,752 stream sites during 2006 and 2007 in Germany (~357,000 km² spatial extent). We quantified the variability and spatial autocorrelation in the traits and orders that are associated with the combined and individual bioclimatic indices. Traits of temperature preference grouping feature that are the products of several other underlying climate-associated traits, and the insect order Ephemeroptera exhibited the strongest response to the bioclimatic indices as well as the highest potential for changing distribution pattern. Regarding individual traits, insects in general and ephemeropterans preferring very cold temperature showed the highest response, and the insects preferring cold and trichopterans preferring moderate temperature showed the

highest potential for changing distribution. We showed that the seasonal radiation and moisture are the most influential bioclimatic aspects, and thus changes in these aspects may affect the most responsive traits and orders and drive a change in their spatial distribution pattern. Our findings support the development of trait-based metrics to predict and detect climate-related changes of freshwater assemblages." 15193. Blanke, A.; Büsse, S.; Machida, R. (2015): Coding characters from different life stages for phylogenetic reconstruction: a case study on dragonfly adults and larvae, including a description of the larval head anatomy of *Epiophlebia superstes* (Odonata: Epiophlebiidae). *Zoological Journal of the Linnean Society* 174: 718-732. (in English) ["The exclusive use of characters coding for specific life stages may bias tree reconstruction. If characters from several life stages are coded, the type of coding becomes important. Here, we simulate the influence on tree reconstruction of morphological characters of Odonata larvae incorporated into a data matrix based on the adult body under different coding schemes. For testing purposes, our analysis is focused on a well-supported hypothesis: the relationships of the suborders Zygoptera, 'Anisozygoptera', and Anisoptera. We studied the cephalic morphology of *Epiophlebia*, a key taxon among Odonata, and compared it with representatives of Zygoptera and Anisoptera in order to complement the data matrix. Odonate larvae are characterized by a peculiar morphology, such as the specific head form, mouthpart configuration, ridge configuration, cephalic musculature, and leg and gill morphology. Four coding strategies were used to incorporate the larval data: artificial coding (AC), treating larvae as independent terminal taxa; non-multistate coding (NMC), preferring the adult life stage; multistate coding (MC); and coding larval and adult characters separately (SC) within the same taxon. As expected, larvae are 'monophyletic' in the AC strategy, but with anisopteran and zygopteran larvae as sister groups. Excluding larvae in the NMC approach leads to strong support for both monophyletic Odonata and Epirocta, whereas MC erodes phylogenetic signal completely. This is an obvious result of the larval morphology leading to many multistate characters. SC results in the strongest support for Odonata, and Epirocta receives the same support as with NMC. Our results show the deleterious effects of larval morphology on tree reconstruction when multistate coding is applied. Coding larval characters separately is still the best approach in a phylogenetic framework." 15195. Boda, R.; Bereczki, C.; Pernecker, B.; Mauchart, P.; Csabai, Z.; (2015): Emergence behaviour of the red listed Balkan Goldenring (*Cordulegaster heros* Theischinger, 1979) in Hungarian upstreams: vegetation structure affects the last steps of the larvae. *J. Insect Conserv.* 19(3): 547-557. (in English) ["In odonates, the emergence behaviour and finding suitable substrates for successful molting may influence the next generation and ultimately can determine the survival of the entire population. Understanding emergence behaviour of endangered species and those granted special conservation status is particularly important. Despite this, little is known about the life history and emergence behaviour of *C. heros*, a characteristic inhabitant of headwater streams. We hypothesised that the taxonomic composition and structure of the vegetation significantly affect the travel distance to the emergence site and the substrate choice. Two stream sections with different riparian zone vegetation were surveyed for exuviae in the emergence periods in two consecutive years, supported with detailed vegetation mapping. Significant differences were found between the vegetation characteristics at the two sites and differences were also found between emergences in edge zones within a site, indicating that the importance of vegetation structure operates within the scale of sites as well as between sites. At the site with more diverse vegetation, smaller horizontal but higher vertical travel distances and more varied emergence substrate choice were found. Habitat composition and complexity appears to determine the emergence behaviour of *C. heros*, so for the successful conservation of this species we recommend choosing appropriate forest management regimes and even maintaining riparian forests in near-pristine condition." 15196. Boda, R.; Bereczki, C.; Pernecker, B.; Mauchart, P.; Csabai, Z.; (2015): Life history and multiscale habitat preferences of the red-listed Balkan Goldenring, *Cordulegaster heros* Theischinger, 1979 (Insecta, Odonata), in South-Hungarian headwaters: does the species have mesohabitat-mediated microdistribution?. *Hydrobiologia* 760: 121-132. (in English) ["Life cycle and microdistribution patterns of *Cordulegaster heros*, a charismatic species for nature conservation, are poorly known. Life history characteristics and multiscale habitat preferences of the larvae were followed for one year in monthly intervals by systematic samplings in eight headwaters, which resulted in data on 2562 individuals. We hypothesized that meso- and microhabitat complexity play an important role in forming the population

structure and microdistribution of the species. Based on the distribution of the consecutive larval instars, duration of later stages and time of molt and emergence, the larval development of *C. heros* in the Mecsek Mountains lasts for at least three, but with a maximum of four years. All three levels of the multi-habitat structure [habitat (sites), and meso. (riffle/pool sequence) and microhabitats (biotic and different particle-sized abiotic types)] have significant effects on the spatial distribution of the larvae. Densities and population structures vary among the sites, but mesohabitat type and microhabitat diversity (heterogeneity within a pool or riffle) govern the microdistribution. *C. heros* prefers pools with small or medium microhabitat heterogeneity and higher proportion of small particle-sized substrates, especially in younger stages. Older larvae are less sensitive for these effects." (Author)] Address: Csabai, Z., Dept of Hydrobiology, Faculty of Science, University of Pécs, Ifjúság útja 6, Pécs, 7624, Hungary. e-mail: csabai@gamma.ttk.pte.hu

15197. Bode-Oke, A.; Zeyghami, S.; Dong, H. (2015): L27.00007: Kinematics and aerodynamics of backward flying dragonflies. *Bulletin of the American Physical Society* 60(21): 1 p. (in English) [Verbatim: Highly maneuverable insects such as dragonflies have a wide range of flight capabilities; precise hovering, fast body reorientations, sideways flight and backward takeoff are only a few to mention. In this research, we closely examined the kinematics as well as aerodynamics of backward takeoff in dragonflies and compared them to those of forward takeoff. High speed videography and accurate 3D surface reconstruction techniques were employed to extract details of the wing and body motions as well as deformations during both flight modes. While the velocities of both forward and backward flights were similar, the body orientation as well as the wing kinematics showed large differences. Our results indicate that by tilting the stroke plane angle of the wings as well as changing the orientation of the body relative to the flight path, dragonflies control the direction of the flight like a helicopter. In addition, our detailed analysis of the flow in these flights shows important differences in the wake capture phenomena among these flight modes.]

15202. Bots, J.; Iserbyt, A.; Van Gossum, H.; Hammers, M.; Sherratt, T.N. (2015): Frequency-dependent selection on female morphs driven by premating interactions with males. *The American Naturalist* 185(6): 141-150. (in English)

["Species showing colour polymorphisms —the presence of two or more genetically determined colour morphs within a single population— are excellent systems for studying the selective forces driving the maintenance of genetic diversity. Despite a shortage of empirical evidence, it is often suggested that negative frequency-dependent mate preference by males (or diet choice by predators) results in fitness benefits for the rare female morph (or prey type). Moreover, most studies have focused on the male (or predator) behaviour in these systems and largely overlooked the importance of female (or prey) resistance behaviour. Here, we provide the first explicit test of the role of frequency-dependent and frequency-independent intersexual interactions in female polymorphic damselflies. We identify the stage of the mating sequence when frequency-dependent selection is likely to act by comparing indexes of male mate preference when the female has little (females presented on sticks), moderate (females in cages), and high (females free to fly in the field) ability to avoid male mating attempts. Frequency-dependent male preferences were found only in those experiments where females had little ability to resist male harassment, indicating that premating interactions most likely drive negative frequency-dependent selection in this system. In addition, by separating frequency-dependent male mating preference from the baseline frequency-independent component, we reconcile the seemingly contradictory results of previous studies and highlight the roles of both forms of selection in maintaining the polymorphism at a given equilibrium. We conclude that considering interactions among all players —here, males and females— is crucial to fully understanding the mechanisms underlying the maintenance of genetic polymorphisms in the wild." 15203. Bouchelouche, D.; Kherbouche-Abrous, O.; Mebarki, M.; Arab, A.; Samraoui, B. (2015): The Odonata of Wadi Isser (Kabylia, Algeria): status and environmental determinants of their distribution. *Revue d'écologie* 70(3): 248-260. (in English, with French summary) ["An odonatological study was carried out during six successive months, from May to October 2013, at Wadi Isser located in the practically unexplored Central North of Algeria. A total of 19 species of Odonata were recorded during the monthly sampling of six stations. Noteworthy was the record of *Lestes numidicus* and *Platycnemis subdilatata*, both Maghrebian endemics. Our results extend considerably towards the west the known distribution of *L. numidicus*, a data deficient (DD) species on the Mediterranean IUCN Red-List. In the light of the present study, no changes in the IUCN Red List classification is proposed with the exception of *L. numidicus* which should be classified as Near-Threatened (NT), pending further investigations. Results also suggest that the variation of the species richness along Wadi Isser may be related to environmental factors. Species richness was positively associated to the density of the riverine vegetation. In contrast, species richness could also be negatively correlated to pollution, an important and recurrent factor of the

erosion of biodiversity of Maghrebian watercourses." (Authors)] Address: Samraoui, B., Laboratoire de Recherche des Zones Humides, Université d'Annaba, 4 rue Hassi-Beida, Annaba, Algeria. E-mail: bsamraoui@yahoo.fr

15204. Bried, J.T.; Dillon, A.M.; Hager, B.J.; Patten, M.A.; Luttbeg, B. (2015): Criteria to infer local species residency in standardized adult dragonfly surveys. *Freshwater Science* 34(3): 1105-1113. (in English) ["For dragonflies, the final exuviae are the most identifiable nymphal stage, can substitute for lethal processing of live animals, and definitively indicate life-cycle completion or reproductive success. However, dragonfly exuviae are difficult to find and identify relative to adults, and species richness in exuvial surveys is generally biased low. We tested readily acquired information in adult surveys as indicators of exuviae presence and, therefore, species residency. Repeated concurrent surveys of adults and exuviae were completed at 32 wetlands in New York and 30 wetlands in Oklahoma, USA. We modelled the occurrence of exuviae as logit-linear functions of adult abundance, detection frequency (across surveys), teneral frequency, and frequency of breeding behaviour while controlling for imperfect detectability. Exuviae occupancy probabilities suggested several reliable indicators of species residency: 1) finding adults on =4 surveys, 2) finding tenerals on =2 surveys, and 3) counting >20 adults on =1 surveys (with caveats). The odds of exuviae occurrence when these conditions were met were ~9 to 18× greater than when no adults were detected. Species residency may be accurately inferred during adult surveys, potentially improving freshwater applications and conservation via dragonflies." 15205. Bried, J.T.; McIntyre, N.E.; Dzialowski, A.R.; Davis, C.A. (2015): Resident-immigrant dichotomy matters for classifying wetland site groups and metacommunities. *Freshwater Biology* 60(11): 2248-2260. (in English) ["(1.) The fact that species have resident (autochthonous) or immigrant (allochthonous) status at any given locality may have strong implications for ecological analysis. (2.) We used wetlands and adult odonates as a model system to evaluate the resident-immigrant dichotomy for two modes of community analysis: (1) grouping sites based on species compositional variation and (2) identifying metacommunity structure. We tested a hypothesis of gradient-structured (non-random) resident occurrence versus unstructured (random) immigrant occurrence in the metacommunity context and predicted the resident occurrence would more effectively partition community variation and produce stronger site groupings than total (resident + immigrant) occurrence. (3.) Site group classification after fractioning out resident occurrence consistently and in some cases dramatically outperformed total occurrence. Resident damselflies produced the strongest classifications, which we attribute to greater dispersal limitation, environmental sorting or both. (4.) As predicted only the resident occurrence led to identifiable metacommunity structures, primarily Clementsian-style

turnover. This suggests the resident occurrence is gradient-driven with species responding similarly to abiotic filters, whereas immigrant occurrence is more opportunistic and random. (5.) The resident-immigrant dichotomy appears to have strong influence on quantitative classification of sites and metacommunities, and species composition of resident adult damselflies is potentially useful for differentiating and indicating site groups of non-forested freshwater wetlands." 15206. Bried, T.J.; Samways, M.J. (2015): A review of odonatology in freshwater applied ecology and conservation science. *Freshwater Science* 34(3): 1023-1031. (in English) ["The academic study of dragonflies and damselflies (odonatology) is well established, but relatively limited attention has been given to odonates in the context of applied ecology and conservation science. We used the Web of Science™ and Odonatological Abstract Service (ISSN 1438-0269) to capture trends in primary literature, characterize study features (habitats, life stages, etc.), identify research themes, and suggest future directions for odonatology in freshwater applied ecology and conservation science. We found no papers in this area prior to 1980, and 411 papers from 1980 through 2013. Nearly 75% of these papers were recent (since 2005) and >40% were very recent (since 2010). We identified several broad and overlapping research themes: 1) model taxa, 2) tools and indicators, 3) odonate-centered work, and 4) methodological issues and improvements (field sampling, data modeling/simulation, conservation/landscape-scale genetics). We found more reliance on fieldbased observational approaches than experiments and model-driven exercises, although the number of papers using model-driven exercises is rapidly increasing. We found a strong focus on adult stages, odonate assemblages, the Odonata as a whole, and studies of particular species. We identified research priorities in areas such as ecological valuation and management, monitoring and assessment, climate change and landscape planning, concordance with other taxa, effects of urbanization, data modeling/simulation, and rare-species ecology and conservation. To help establish an identity and facilitate communication, we suggest naming this diverse realm "applied odonatology". We think applied odonatology has a good future for a range of topics from conservation genetics and population ecology to assessments of anthropogenic impacts and the conservation of biodiversity." (Authors)] Address: Bried, T.J., Department of Integrative Biology, Oklahoma State University, Stillwater, Oklahoma 74078 USA

15207. Brockhaus, T. (2015): Die Libellenfauna des Himalaya mit besonderer Berücksichtigung der Arten des Bergregenwaldes (Insecta: Odonata). *Hartmann & Weipert: Biodiversität und Naturlandschaft im Himalaya V. - Erfurt 2015*: 287-320. (in German, with English summary) ["The Dragonflies of the Himalayas with special emphasis on the species of mountainous rain forests (Insecta: Odonata):

The area of reference includes the North West Himalayas (India with the states of Jammu & Kashmir, Himachal Pradesh, Uttarakhand), the Central Himalayas (Nepal, India, Darjeeling in the state West Bengal and the state of Sikkim) and Eastern Himalayas (Bhutan, India, state of Arunachal Pradesh). and also the southeastern Himalayan foothills with the Indian states of Meghalaya and Nagaland. After a comprehensive review of the checklist in Brockhaus (2009) from the Himalayas and its peripheral regions 331 species of dragonflies are known. For some species are represented maps, based on my own observations and from the literature. Most species are part of the Oriental Sino-Indian faunal region. In the mountainous rain forests of the Himalayas habitat specialists of mountain streams and rivers live. They include also the endemic species in the Himalayas *Epiophlebia laidlawi*, *Davidius abberans* and *Neallogaster ornatus*. The inhabited areas differs between 400 to 4050 m above sea level. The endemic species can only above 1300 m above sea level be found. A comparison of the similarity of the faunas of the regions shows that the similarity decreases from east to west. One reason for this is the proportion of Palaearctic species in the fauna of Northwestern Himalayas. For the species of the Palaearctic respectively Holarctic region *Symplocma paedisca*, *Aeshna juncea*, *A. mixta* and *Anax parthenope* distribution maps are presented for the Himalayan area. The phylogeography and its relevance to an update of the IUCN Red List of Threatened Species are discussed. The states of the Himalayan region are worldwide exemplary in the designation of protected areas like National parks. Large protected areas are the most effective means to maintain the habitats of the treated species. Currently we still know so little about their really distribution and ecological needs." 15209. Brockhaus, T.; Roland, H.-J.; Benken, T.; Conze, K.-J.; Günther, A.; Leipelt, K.G.; Lohr, M.; Martens, A.; Mauersberger, R.; Ott, J.; Suhling, F.; Weihrauch, F.; Willigalla, C. (2015): Atlas der Libellen Deutschlands (Odonata). *Libellula Supplement* 14: 1-394. (in German, with English summary) ["Atlas of Odonata of Germany – For the first time, we present a complete overview about the distribution of all dragonfly species occurring in Germany. The atlas is based on a data collection compiled during 2007-2012, which was organized by the atlas-working-group of Gesellschaft deutschsprachiger Odonatologen. The database comprises more than 1.16 million point locality data sets delivered by more than 2,900 persons from all 16 federal states.

Whereas few data date back as far as the year 1800 most are more recent; most recent data are from 2011, for some species with current drastic distribution changes from 2013. While only 1 % of the records are from the first 150 years, more than 63 % are from later than 1995. Since 1995 data were recorded for 79 of the 81 species occurring in Germany, while *Coenagrion hylas* and *Onychogomphus unca* were only observed in Germany before 1995 and are now considered as extinct. The atlas comprises distribution maps for all of the 81 dragonfly species. Each map grid square represents a so called Messtischblatt (MTB) with an area of ca 130 km². For each species the distribution situation is depicted for three time periods: before 1980, 1980-1995, and after 1995. The atlas also includes species monographs where the vertical and horizontal distributions in Germany (according to the database) as well as habitat, life cycle, population trends, and threats are described. Finally, an overview about records of exotic dragonflies recorded in Germany is presented. Basing on this atlas the Red List of Odonata of Germany is presented not in this article but in this issue as well as an extensive presentation of fossil odonate records from Germany.] Address: Brockhaus, T., An der Morgensonne 5, D-09387 Jahnsdorf, Germany. 15210. Brodin, T.; Piovano, S.; Fick, J.; Klaminder, J.; Heynen, M.; Jonsson, M. (2015): Ecological effects of pharmaceuticals in aquatic systems—impacts through behavioural alterations. *Philosophical Transactions of the Royal Society of London B: Biological Sciences* 369: 20130580: 10 pp. (in English) ["The study of animal behaviour is important for both ecology and ecotoxicology, yet research in these two fields is currently developing independently. Here, we synthesize the available knowledge on drug-induced behavioural alterations in fish, discuss potential ecological consequences and report results from an experiment in which we quantify both uptake and behavioural impact of a psychiatric drug on a predatory fish (*Perca fluviatilis*) and its invertebrate prey (*Coenagrion hastulatum*). We show that perch became more active while damselfly behaviour was unaffected, illustrating that behavioural effects of pharmaceuticals can differ between species. Furthermore, we demonstrate that prey consumption can be an important exposure route as on average 46% of the pharmaceutical in ingested prey accumulated in the predator. This suggests that investigations of exposure through bioconcentration, where trophic interactions and subsequent bioaccumulation of exposed individuals are ignored, underestimate exposure. Wildlife may therefore be exposed to higher levels of behaviourally altering pharmaceuticals than predictions based on commonly used exposure assays and pharmaceutical concentrations found in environmental monitoring programmes." 15211. Buczek, K. (2015): Human impact on the evolution of a landslide lake. Case Study: Lake Pucółowski Stawek in the Gorce Mts. *Prace Geograficzne* 142: 41-56. (in Polish,

with English summary) ["The paper presents the results of a study of the human impact on the evolution of a landslide lake. An example of a landslide lake subjected to strong anthropogenic influence is that of the Pucółowski Stawek Lake in the Gorce Mts. Historical data analysis, interviews with local inhabitants, and several surveys of the lake area and shoreline at various moments of its history have enabled us to reconstruct the lake's evolution since the early 20th century. Research has shown that since the first field description in 1932, the lake did not become overgrown (as it is very common for this type of lake), until the late 1980s. The reason for its preservation has been human activity. The subsequent acceleration of the overgrowing of the Pucółowski Stawek Lake has been connected with the cessation of mowing, grazing and peat extraction in the lake basin. This has led to the full disappearance of this water body and the reservoir to fen type peat bog. In December 2011, the owners of the lake deepened the lake basin and removed organic sediments at the same time. This led to lake reactivation, although with a changed shoreline. The area of the lake basin decreased about 22% compared with its size in 1968. The same is true of the shoreline development factor which is now 1.08 compared with 1.23 in 1968. Dynamic plant succession has been observed since 2012 in the Pucółowski Stawek Lake, and the lake area has decreased about 27% compared with its size in 2012. The consequences of the action which led to the deepening of the lake significantly affected the fauna and flora of the reservoir, causing improvement in amphibians' habitat conditions. Human activity in this area has led to water reservoir reactivation, giving it unique landscape value as well as increasing its biodiversity by restoring adequate habitat conditions." (Authors) The publication includes a passing reference to *Leucorrhinia dubia*.] Address: Buczek, K., Uniwersytet Jagielloński, Instytut Geografii i Gospodarki Przestrzennej, Gronostajowa 7, 30-387 Kraków, Poland. 15213. Buczyński, P. (2015): Dragonflies (Odonata) of anthropogenic waters in middle-eastern Poland. Olsztyn 2015: 272 pp. (in English, with Polish summary) ["The aim of this work is an analysis of the occurrence of dragonflies (Odonata) in the anthropogenic water bodies, on example of a selected, contiguous geographic region. The author discusses data collected in middle-eastern Poland in the years of 1992–2013 (mainly 2001–2011). The research encompasses 327 anthropogenic sites and, for comparison, 630 water

bodies of natural origin. They presented a whole spectrum of essential habitats of the dragonflies in the region. 66 species of dragonflies were found: 64 in anthropogenic and 65 in natural waters. The occurrence of the species in both types of waters was analyzed, and based upon that analysis a division into 5 groups was introduced: anthropophiles of 1st degree, anthropophiles of 2nd degree, anthropotolerant species, anthropoxenes, and anthropophobes. The fauna of the dragonflies of selected types of anthropogenic waters and the most important environmental factors shaping them were discussed. The importance of anthropogenic waters for the protection of the dragonfly species, their assemblages typical of natural waters and the general richness of species were assessed. Also described were the perspectives for their active protection. The role of the anthropogenic waters in the expansion of the thermophilous species was assessed. The results collected were subject to a critical discussion in comparison to the data in literature, with special emphasis being placed on data from middle and middle-eastern Europe." 15214. Büsse, S.; Helmker, B.; Hörschemeyer, T. (2015): The thorax morphology of *Epiophlebia* (Insecta: Odonata) nymphs – including remarks on ontogenesis and evolution. *Sci Rep.* 2015; 5: 12835: 14 pp. (in English) ["The species of *Epiophlebia* are unique among the recent Odonata in showing a mixture of morphological characters of dragonflies (Anisoptera) and damselflies (Zygoptera). The status of the four described extant species of *Epiophlebia* is disputable from a genetic as well as from a morphological point of view. Here we present an analysis of the thoracic musculature of different nymphal instars of *Epiophlebia laidlawi* and *Epiophlebia superstes* to elucidate their morphology and ontogenetic development. In total, 75 muscles have been identified in the thorax of *Epiophlebia*. This represents the highest number of thoracic muscles ever found in any odonate. It includes six muscles that are reported for the first time for Odonata, and three of these are even new for Pterygota. In total, our results indicate that *Epiophlebia* has the most ancestral thoracic morphology among Odonata." 15215. Cabrera-Guzmán, E.; Crossland, M.R.; Shine, R. (2015): Invasive cane toads as prey for native arthropod predators in tropical Australia. *Herpetological Monographs* 29(1): 28-39. (in english) ["The successful spread of invasive Cane Toads (*Rhinella marina*) across tropical Australia has been attributed to a lack of biotic resistance, based upon the inability of most anuran-eating vertebrate predators to tolerate the powerful chemical defenses of the toads. However, despite their high species richness, invertebrates have been much less studied than vertebrates as predators of Cane Toads. Our field and laboratory studies show that

toads are killed and consumed by a phylogenetically diverse array of arthropod taxa. No arthropod predators consumed toad eggs in our laboratory experiments, but fishing spiders, water beetles, water scorpions, and dragonfly nymphs killed toad tadpoles, and ants and fishing spiders killed metamorph toads. Published accounts report predation on toads by crustaceans and hemipterans also. In our experiments, no predators showed any overt ill effects from consuming toad tissue. Dragonfly nymphs (*Pantala flavescens*) and fishing spiders (*Dolomedes facetus*) selectively took Cane Toad tadpoles at higher rates than some simultaneously offered native frog tadpoles. In combination with published data, our experiments suggest that the tadpoles and metamorphs of Cane Toads face high predation rates from the diverse and abundant invertebrate fauna of aquatic and riparian habitats in tropical Australia. The invasion of Cane Toads can potentially have positive effects on populations of many native animal species." 15216. Callahan, M.S.; McPeck, M.A. (2015): Multi-locus phylogeny and divergence time estimates of *Enallagma* damselflies (Odonata: Coenagrionidae). *Molecular Phylogenetics and Evolution* 94: 182-195. (in English) ["Highlights: • *Enallagma* damselflies show complex diversification across North America and Eurasia. • Four subclades radiated in the Pleistocene to produce 28 extant species. • Both speciation and extinction rates increased over the last 1.5 million years. Abstract: Reconstructing evolutionary patterns of species and populations provides a framework for asking questions about the impacts of climate change. Here we use a multilocus dataset to estimate gene trees under maximum likelihood and Bayesian models to obtain a robust estimate of relationships for a genus of North American damselflies, *Enallagma*. Using a relaxed molecular clock, we estimate the divergence times for this group. Furthermore, to account for the fact that gene tree analyses can overestimate ages of population divergences, we use a multi-population coalescent model to gain a more accurate estimate of divergence times. We also infer diversification rates using a method that allows for variation in diversification rate through time and among lineages. Our results reveal a complex evolutionary history of *Enallagma*, in which divergence events both predate and occur during Pleistocene climate fluctuations. There is also evidence of diversification rate heterogeneity across the tree. These divergence time estimates provide a foundation for addressing the relative significance of historical climatic events in the diversification of this genus." (Authors)] Address: Callahan, Melissa, Department of Biological Sciences, Dartmouth College, 78 College Street, Hanover, NH 03755, USA. E-mail: callahan.ms@gmail.com

15217. Cao, L.; Fu, X.; Wu, K. (2015): Development of 10 microsatellite markers from *Pantala flavescens* and their applicability in studying genetics diversity. *Molecular Biology Reports* 42(8): 1275-1279. (in English) ["*P. flavescens* is

one of the most common species among migration dragonflies. It is often encountered in large swarms during migration or directed dispersal flights. For a better understanding of its gene flow, genetic structure and migration patterns throughout the world, 10 polymorphic microsatellite markers were isolated in this study. We respectively collected 32 *P. flavescens* from three places (Hunan, Liaoning and Heilongjiang) and 20 *P. flavescens* from Beijing. Partial genomic libraries containing microsatellite sequences were constructed with magnetic-bead enrichment method. By screening, sequence analysis, PCR amplification and so on, ten 10 polymorphic microsatellite markers were isolated. In order to assess their applicability, genetic diversity of these novel markers was tested in 96 individuals from three populations in China (Hunan, Liaoning and Heilongjiang). These markers were highly polymorphic, with 3–12 alleles per markers. The observed (H_o) and expected (H_e) heterozygosities ranged 0.321–0.667 and from 0.531 to 0.948 respectively. The genetic difference between Hunan and Liaoning is 0.429, while the genetic difference between Liaoning and Heilongjiang is 0.0508. These microsatellite markers for *P. flavescens* were developed for the first time, and will be a powerful tool for studying population genetic diversity and dispersal behaviour of *P. flavescens* in China and worldwide." (Authors)] Address: Cao, L., Institute of Plant Protection, Chinese Academy of Agricultural Sciences, No. 2, Yuanmingyuan West Road, Haidian District, Beijing, China. E-mail: clzclz1011@163.com

15218. Carle, F.L.; Kjer, K.M.; May, M.L. (2015): A molecular phylogeny and classification of Anisoptera (Odonata). *Arthropod systematics & phylogeny* 73(2): 281-301. (in English) ["A phylogeny of Anisoptera employing 510 representatives of 184 genera (of ca. 380) in 11 families is presented based on an analysis of over 10,000 nucleotides from portions of the large and small subunit nuclear and mitochondrial ribosomal RNA's, the mitochondrial protein coding genes COI and COII, and portions of the nuclear protein coding genes EF-1 α and Histone H3. Ribosomal sequences were structurally aligned and sequences carefully checked to eliminate alignment errors, contamination, misidentification and paralogous gene amplicons. Both the RAXML and Bayesian topology based on consolidation of data at the generic level is ((Austropetaliidae, Aeshnidae), ((Gomphidae, Petaluridae), ((Chlorogomphidae, (Neopetaliidae, Cordulegastridae))), (Synthemistidae, (Macromiidae, (Corduliidae, Libellulidae)))))). As the positions of Petaluridae, Chlorogomphidae, Neopetaliidae, and Cordulegastridae are weakly supported, possible alternative hypotheses are discussed. New taxonomic groups established include: in Gomphidae, Stylogomphini trib.n. and Davidioidini trib.n., and in Libellulidae, Dythemistinae subfam.n. including Dythemistini trib.n., Pachydiplactini trib.n. and Elgini trib.n. New taxonomic arrangements include: placement of Hemigomphini in Ictinogomphinae, and provisional expansion of Synthemistidae to include Gomphomacromiinae and a number of genera formerly placed in several small subfamilies of Corduliidae. Idomacromiinae is

placed sister to remaining Synthemistidae s.l. based on molecular analysis of *Idomacromia* Karsch and *Oxygastra* Selys. Hemicorduliidae and Macrodiplactidae are nested well within Corduliidae and Libellulidae, respectively, and therefore are not accorded family rank. Eleven monophyletic subdivisions of Libellulidae are tentatively recognized as subfamilies: Dythemistinae subfam.n.; Sympetrinae (including Leucorrhiniini and Rhythemistini); Macrodiplactinae; Brachydiplactinae; Tetrathemistinae; Trameinae; Zyxomatinae; Palpopleurinae; Diastatopidinae; Pantalinae (including Trithemistini and Onychothemistini); and Libellulinae. Zygonychini is paraphyletic to and therefore included within Onychothemistini." 15219. Catania, S.V.L.; McCauley, S.J. (2015): Evaluating the use of coded-wire tags in individually marking Odonata larvae. *The Canadian Entomologist* 148(3): 371-374. (in English) ["We tested a potential new tool for marking Odonata larvae internally, evaluating the retention rates of injected coded-wire tags (CWT) and the effects of these tags on larval performance. Two species of dragonfly larvae (*Epitheca canis* and *Leucorrhinia intacta*) were injected with CWT. Tag loss rates were assayed over experimental periods of 22 and 60 days, respectively for the two species. To assess whether tagging had negative effects on larvae, mortality, and growth of tagged larvae were compared to untagged larvae held in the same conditions. Tag retention rates were high (92–100%) and CWT were easily retrieved from preserved larvae via dissection, permitting most tagged larvae to be individually identified. There was 100% survival in larvae injected with CWT and tags do not appear to impair growth. The high retention and retrieval rates of this marking approach combined with no increase in mortality associated with tagging suggest that CWT are a useful means of individually labelling a large number of Odonata larvae in a time-efficient manner." (Authors)] Address: Catania, S.V.L., .Dept of Biology, University of Toronto Mississauga, Mississauga, Ontario, Canada L5L 1C6

15220. Catil, J.-M. (coord.) (2015): Atlas commenté des libellules du Gers. Centre Permanent d'Initiatives pour l'Environnement Pays Gersois – L'Isle-de-Noé: 80 pp. (in French) [accessible sur www.cpie32.org.] Address: CPIE Pays Gersois, Catil, J.-M., Au Château, 32300 L'Isle-de-Noé, France. 15221. Cech, M.; Cech, P. (2015): Non-fish prey in the diet of an exclusive fish-eater: the Common Kingfisher *Alcedo atthis*. *Bird Study* 62: 457-465. (in English) ["Capsule: Non-fish prey constitutes an important component of the diet of many fish-eating birds. Aims: In the present study, the role of non-fish prey in the diet of *A. atthis* was evaluated. Methods: The species and size spectrum of prey in the diet was studied at 15 nest sites on 6 trout streams, 1 river and 1 reservoir in the Czech Republic, using the analysis of the nest sediment. Results: 16 933 individual prey items were

identified (99.93% fish and 0.07% non-fish prey). ... The remains of non-fish prey were detected in only 5 of 30 nest sediments. The non-fish prey were mostly composed of large aquatic insect larvae: dragonflies *Anax* sp. and *Aeshna* sp., *Gomphus vulgatissimus* and Great Diving Beetle *Dytiscus marginalis*. Kingfishers also took Spiny-cheek Crayfish *Orconectes limosus*, Newt *Triturus* sp. and a Lizard *Lacerta* sp. The estimated sizes of the non-fish prey ranged from 30 to 90 mm. Conclusion: The catch of non-fish prey appears to be accidental, and is more likely a result of target misinterpretation (fish-like body and fish-like movement) than a Kingfisher regularly switching to prey other than fish. The unique finding of a Lizard is the first record of an amniotic vertebrate in the diet of Common Kingfisher." 15222. Chama, L.; Siachoono, S. (2015): Effectiveness of birds, butterflies, dragonflies, damselflies and invertebrates as indicators of freshwater ecological integrity. *Geophysical Research Abstracts* 17, EGU2015-13383, 2015, EGU General Assembly 2015: (in English) [Verbatim: Human activities such as mining and agriculture are among the major threats to biodiversity globally. Discharges from these activities have been shown to negatively affect ecological processes, leading to ecosystem degradation and species loss across biomes. Freshwater systems have been shown to be particularly vulnerable, as discharges tend to spread rapidly here than in other ecosystems. Hence, there is need to routinely monitor the quality of these systems if impacts of discharges from human activities are to be minimised. Besides the use of conventional laboratory techniques, several studies have recently shown that organisms such as birds, butterflies, dragonflies, damselflies and invertebrates are also good indicators of ecological integrity and should therefore be used as alternatives to monitoring the quality of various ecosystems. However, most of these studies have only studied one or two of these organisms against ecosystem health, and it remains unclear whether all of them respond similarly to changes in different drivers of environmental change. We investigated the response of the diversity of birds, butterflies, dragonflies, damselflies and invertebrates to changing water quality along the Kafue River in Zambia. Sampling was done at 13 different sampling points stretching over a distance of 60km along the river. At each point, both the diversity of each organism and the water quality were assessed. Water quality was determined by testing its temperature, pH, redox, electrical conductivity, turbidity and copper parameters. We then tested how the diversity of each organism responded to changes in these water parameters. All water parameters varied significantly across sampling points. The diversity of birds and damselflies remained unaffected by any of the water parameters used. However, the diversity of butterflies reduced with increasing pH, turbidity and copper, albeit it remained unaffected by other water parameters. The diversity of dragonflies reduced with increasing redox, electrical conductivity and turbidity, but remained unaffected by other water parameters.

The diversity of invertebrates reduced with increasing redox and copper, but remained unaffected by other water parameters. Generally, these results suggest that these organisms, especially butterflies, dragonflies and invertebrates can indeed be used as indicators of changing water quality and ecological integrity in particular. However, their use is limited to specific, rather than, all water parameters. Therefore, the decision as to which organisms to use should largely depend on which water quality parameters are to be tested.] Address: Chama, L., Department of Zoology and Aquatic Sciences, School of Natural Resources, Copperbelt University, Jambo Drive, Kitwe, Zambia

15223. Chandler, H.C.; Haas, C.A.; Gorman, T.A. (2015): The effects of habitat structure on winter aquatic invertebrate and amphibian communities in pine flatwoods wetlands. *Wetlands* 35: 1201-1211. (in English) ["Natural disturbances play a critical role in structuring many ecosystems. In the southeastern United States, fire suppression and exclusion have removed the natural disturbance regime from many ecosystems, including ephemeral wetlands embedded within longleaf pine forests. We sampled aquatic invertebrate and amphibian communities in 21 pine flatwoods wetlands in northwest Florida from 2012 to 2014. Our objectives were to quantify amphibian and invertebrate community structure, identify differences in amphibian communities across an environmental gradient, and identify how invertebrate communities responded to wetland habitat characteristics. Amphibian communities were more diverse in wetlands with longer hydroperiods but were similar across wetlands with different vegetation structures. To examine the effects of wetland characteristics on aquatic invertebrate communities, we created a set of a priori models relating the abundance of isopods, chironomids, and damselflies to wetland characteristics. The best-approximating models indicated that isopods and damselflies were more abundant in wetlands that were not fire-suppressed. Similarly, total invertebrate abundance was higher in sections of wetlands with low canopy cover when compared to sections of the same wetlands with high canopy cover. Restoration of vegetation structure in wetlands that have experienced long-term fire suppression and wetlands that support longer hydroperiods should be a management priority." 15228. Chauhan, A.; Verma S.C.; Thakur, M. (2015): Bio-assessment of water quality of mountainous streams under different land uses in Solan district of Himachal Pradesh, India. *International Journal of Bio-resource and Stress Management* 6(1): 161-166. (in Water quality, land uses, seasons, aquatic insects) ["Investigations were carried out in the Environmental Biology Laboratory of Department of Environmental Science, Dr Y S Parmar University of Horticulture and Forestry, Nauni, Solan, Himachal Pradesh, India during 2011–2012. Aquatic insects fauna were sampled from mountainous streams of Kandaghat block situated in Solan district under different land uses (agriculture, forest and urban) seasons (rainy, winter and summer). The sampled aquatic insects were identified upto family level by using aquatic insect identification keys with help of stereoscopic binocular microscope. A total of 80 individuals m² and 59 individuals m² of aquatic insects were recorded under agriculture and urban land uses, respectively. Among all the land uses, forest land use recorded highest aquatic insects (107 m²). Maximum aquatic insects (123 m²) was during summer season with simpson's biodiversity index of 0.01, whereas agriculture land use (0.11) was highest under different land uses. Maximum diversity of insects indicated less disturbance of the streams. EPT (Ephemeroptera, Plecoptera and Coleoptera) index for agriculture, urban and forest land uses was 3.46, 3.70 and 3.56, respectively. Percentage of individuals of Trichoptera in water bodies under agriculture, Urban and Forest land use were 12.60, 10.98

and 10.16%, respectively. Hemiptera were maximum (7.31%) under forest land use and minimum in Urban land use (2.03%), whereas order Odonata were maximum under Forest land use (9.31%) followed by urban (5.69%) and agriculture land use (4.47%). This indicated that aquatic insect fauna showed variation in distribution and abundance as well as biotic indices in mountainous streams under different land uses thereby reflecting good water quality." (2015): Mitochondrial genome of a flashwing demoiselle, *Vestalis melania* from the Philippine Archipelago. *Mitogenome Announcement* 26(5): 720-721. (in English) ["This study determined the first complete mitochondrial genome of a demoiselle, *V. melania* using long-range PCR and a primer walking approach. This mitogenome is 16,685 bp long and contains the entire set of 37 genes and an A β T-rich control region typically found in insects. Presently, this mitogenome is the largest mitogenome of all available odonates, mainly because of its long A β T-rich region (2036 bp). The gene arrangement of the *V. melania* mitogenome is identical to that of other known odonates. The intergenic spacer s5 shared by the Anisoptera is absent in *V. melania*, which supports the view that the absence of the s5 spacer is a synapomorphy of the Zygoptera." 15230. Chen, Y.H.; Skote, M. (2015): Study of lift enhancing mechanisms via comparison of two distinct flapping patterns in the dragonfly *Sympetrum flaveolum*. *Phys. Fluids* 27, 033604 (2015); <http://dx.doi.org/10.1063/1.4916204>: 24 pp. (in English) ["The computational fluid dynamic model of a live-sized dragonfly (*Sympetrum flaveolum*) hindwing is simulated according to the in-flight flapping motions measured in kinematic experiments. The flapping motion of the simulated wing is accomplished by dynamically re-gridding the wing-fluid mesh according to the established kinematic model for each flapping pattern. Comparisons between two distinct flapping patterns (double figure-eight and simple figure-eight) are studied via analysis of the aerodynamic forces and flow field structures. The result shows that additional lift is generated during supination and upstroke for the double figure-eight pattern, while maximum thrust is generated during pronation for the simple figure-eight pattern. In addition, through our comparisons of the different kinematics, we are able to reveal the mechanism behind the leading edge vortex stabilization prior to supination and the kinematic movement responsible for additional lift generation during supination. By increasing the translational deceleration during stroke-end rotations in the double figure-eight flapping pattern, a trailing edge vortex is formed which is stronger as compared to the single figure-eight flapping pattern, thus enhancing the lift." (2015): Effect of flood depth on Rice Water Weevil (Coleoptera: Curculionidae) populations in Florida rice fields. *Journal of Entomological Science* 50(4): 311-317. (in English) ["The rice water weevil, *Lissorhoptrus oryzophilus* Kuschel, is an important pest of rice (*Oryza sativa* L.) grown in Florida. Reports on the effect of flood depth on rice water weevil populations have been inconsistent. Our objective was to determine if flood depth has any significant effect on rice water weevil populations and other arthropods in rice grown in Florida. Sampling was conducted using adult foliar damage scars, core samples for larvae, and sweep nets for arthropods above the water. Results showed that shallow flooding reduced rice water weevil populations in Florida. Sweep net data showed that flood depth had little, if any, effect on populations of damselflies (Odonata), leafhoppers (Cicadellidae), spiders (Arachnida), or stink bugs (*Oebalus* spp.)." 15232. Chovanec, A.; Schindler, M.; Waringer, J.; Wimmer, R. (2015): The dragonfly association index (Insecta: Odonata) - a tool for the type-specific assessment of lowland rivers. *River Research and Applications* 31(5): 627-638. (in English) ["Species traits of 57 Odonata species occurring in the Austrian bioregion Eastern Ridges and Lowlands (ecoregion Hungarian Lowlands; Illies, 1978) were defined by factor loadings of 12 habitat parameters: stream sections crenon, rhithron and potamon; flow velocity; standing water; temporary water; size of water body; open water; open banks; submerged macrophytes; reed; and riparian trees. On the basis of the species-specific configurations of these habitat parameters, cluster analysis revealed seven dragonfly associations with different habitat needs: association of open waters, association of sparsely vegetated banks, association of reed and riparian trees, association of reed and submerged macrophytes, association of temporary waters, rhithron association and potamon association. Correlations between the associations' habitat requirements and the habitat parameters of the seven (near-)natural river types, which are present in this bioregion were performed to define river type-specific association compositions. From these results, a dragonfly association index was created to assess the ecological status of these rivers within the five-tiered system of the European Union Water Framework Directive, emphasizing hydro-morphological aspects by comparing the type-specific reference situation with the actual status quo of dragonfly colonization. The method was applied at different rivers, particularly for the purpose of evaluating restoration measures." 15234. Collins, S.D.; McIntyre, N.E. (2015): Modeling the distribution of odonates: a review. *Freshwater Science* 34(3): 1144-1158. (in English) ["Species distribution models (SDMs) can be used to answer a variety of questions about Odonata (dragonflies and damselflies) distributions because locality data for species are readily available. We provide an overview of SDMs and review 30 studies that have used SDMs to examine factors governing odonate distributions in current and projected future scenarios. These studies had objectives that included predicting the potential geographical distribution of a species based on scattered records, quantifying hotspots for biodiversity and identifying reserve gaps, assessing species' environmental requirements and limitations, quantifying dispersal abilities of species with different life histories, studying niche conservatism among sympatric species, modeling the effect of forecasted climate change on species distributions, and examining the efficacy of different modelling approaches. We point out limitations in the use of SDMs for these purposes, including effects of limited taxonomic coverage and limited spatial resolution at fine scales. We also highlight potential future areas where use of SDMs can advance our knowledge of odonate-environment interactions." 15235. Córdoba-Aguilar, A.; Vrech, D.E.; Rivas, M.; Nava-Bolaños, A.; González-Tokman, D.; González-Soriano, E. (2015): Allometry of male grasping apparatus in odonates does not suggest physical coercion of females. *Journal of Insect Behavior* 28(1): 15-25. (in English) ["Male abdominal grasping apparatus that are used to secure a female prior, during and after mating, are widespread in arthropods. The scarce evidence regarding its selective regime suggests that they are male adaptations to circumvent female mating decisions, as predicted by the sexual conflict hypothesis. A recent discussion regarding this way of selection suggests that, similar to weapons and traits that have to do with physical endurance, grasping apparatus should show hyperallometry (proportionally larger compared to body size) as an indication of selection towards increased size. We have tested this idea by measuring the length, width and area of the grasping apparatus of five dragonfly species (*Anax junius*, *Rhionaeschna multicolor*, *Dythemis nigrescens*, *D. sterilis* and *Phyllogomphoides pacificus*). We used two proxies of body size (wing and body length). Our measures did not indicate any pattern of hyperallometry. Thus, the grasping apparatus in these animals does not seem to be positively selected for increased size as would be expected if they were forcing females to mate. Given this, we discuss three other explanations for the maintenance of the grasping apparatus in odonates: 1) a firm grip that secures the tandem and mating position; 2) courtship devices subject to female choice; and, 3) isolation structures that mechanically prevent interspecific matings. The first hypothesis, however, could not explain the highly elaborated and species specific morphology of grasping apparatus in these animals. Support for the second hypothesis comes from the fact that odonate females have mechanoreceptor sensilla embedded in their mesostigmal plates (the place grabbed by the grasping apparatus). For the third hypothesis, coevolutionary patterns in morphology in the grasping apparatus and mesostigmal plates in some Zygoptera can also be used as support." 15236. Córdoba-Aguilar, A.; Munguía-Steyer, R. (2015): To be or not to be? Mating success and survival trade offs when switching between alternative reproductive tactics. *Journal of Evolutionary Biology* 28(11): 2119-2124. (in English) ["Hormones underlie the decision of assuming a territorial or a nonterritorial role, with territorial individuals usually having higher hormonal levels than nonterritorial individuals. Since a territorial status is linked to higher mating opportunities, it is unclear why animals do not keep high hormonal levels and one explanation is that this would imply survival costs. We have tested this using males of the territorial damselfly *Argia emma* in the field. We increased juvenile hormone levels using methoprene in both territorial and nonterritorial males and predicted: a) that males will keep (the case of territorial males) or become (the case of nonterritorial males) territorial after hormonal increase, and b)

there will be an increase in mating success for nonterritorial males only and an impaired survival for both male tactics. Hormonally-treated males remained or became territorial but had their survival impaired compared to control groups. Also, hormonally-treated, ex-nonterritorial males increased their mating success compared to the other control, nonterritorial males. The reduced survival can be explained proximally by the energy devoted either to the enhanced aggression showed during territory defense or immune function (as detected previously in damselflies). Although nonterritorial males may increase their mating success by switching to a territorial tactic, they are possibly unable to do it naturally as juvenile hormone is dietary dependent and usually nonterritorial animals are in poorer condition than territorial animals." (Authors)] Address: Córdoba-Aguilar, A., Depto de Ecología Evolutiva, Instituto de Ecología, Univ. Nacional Autónoma de México, Apdo. Postal 70-275, Ciudad Universitaria, 04510, México, D. 15237. Corser, J.D.; White, E.L.; Schlesinger, M.D. (2015): Adult activity and temperature preference drives region-wide damselfly (Zygoptera) distributions under a warming climate. *Biology Letters* 2015 11 20150001; DOI: 10.1098/rsbl.2015.0001. Published 15 April 2015 : 5 pp. (in English) ["We analysed a recently completed statewide odonate Atlas using multivariate linear models. Within a phylogenetically explicit framework, we developed a suite of data-derived traits to assess the mechanistic distributional drivers of 59 species of damselflies in New York State (NYS). We found that length of the flight season (adult breeding activity period) mediated by thermal preference drives regional distributions at broad (105 km²) scales. Species that had longer adult flight periods, in conjunction with longer growing seasons, had significantly wider distributions. These intrinsic traits shape species' responses to changing climates and the mechanisms behind such range shifts are fitness-based metapopulation processes that adjust phenology to the prevailing habitat and climate regime through a photoperiod filter." 15238. Courville, A. (2015): Organic carbon transport by aquatic insect emergence from permanent and temporary ponds. Departmental Honors in the Department of Environmental Sciences, Texas Christian University, Fort Worth, Texas: (in English) ["Small man-made ponds are the numerically dominant water body in the Great Plains, and they have been hypothesized to be sources of organic carbon (i.e. energy) to surrounding terrestrial food chains. Aquatic insects that live as immature forms in ponds emerge from the ponds as adults and transfer organic carbon from ponds to terrestrial ecosystems (i.e. carbon flux). Terrestrial predators such as birds and bats consume these insects. Pond permanence and the presence of fish are the primary factors controlling insect community structure and carbon flux. Permanent ponds contain fish, whose predation suppresses large aquatic insects and thereby reduces emergence and carbon flux. Temporary ponds that dry and refill

periodically do not contain fish and have larger insect species and higher levels of emergence and carbon flux. The objective of my study was to assess how the flux of carbon from a permanent pond compares to a temporary pond after refilling and to evaluate the taxa-specific carbon flux in permanent and temporary ponds. I examined insect emergence in five permanent ponds with fish and in five temporary ponds that had dried and been refilled at the Eagle Mountain Fish Hatchery in Fort Worth, TX. I monitored the emergence of insects using floating insect emergence traps over a 10-week period. I captured over 48,000 insects, which were preserved in alcohol, counted and measured for body size. Insects were dried and weighed to determine biomass and carbon flux. Carbon flux from temporary ponds started within a week of pond refilling in the form of small midges, and increased throughout the 10-week period as increasingly larger taxa such as mayflies, damselflies, and dragonflies began to emerge. I found that it took two weeks after refilling for temporary ponds to have higher carbon flux than permanent ponds." (Authors)] Address: not stated

15239. Cowan, E.M.; Cowan, P.J. (2015): Odonata (Insecta) at a wadi Pool near Nizwa, northern Oman. *Journal of Threatened Taxa* 7(9): 7538-7546. (in English) ["Fourteen damselfly and dragonfly species were recorded in 68 visits to a wadi pool in northern Oman, March 2012 to June 2014. All identifications were based on photographs. Apparently the pool has a core community of eight resident species (*Ischnura evansi*, *Pseudagrion decorum*, *Anax imperator*, *Orthetrum chrysostigma*, *O. sabina*, *Crocothemis erythraea*, *Trithemis annulata*, *T. kirbyi*). *Paragomphus sinaiticus*, globally Near Threatened, was regularly recorded." 15240. Cuevas, M.D. (2015): The potential and promotion of entotourism in Gunung Ledang, Johor, Malaysia. Masters thesis, Universiti Tun Hussein Onn Malaysia: xx, 106 pp. (in English) ["This research tries to provide the scientific evidence that insect (including Odonata) tourism or entotourism has potential and is viable. This is achieved through two methods – field observation and data collection, and through questionnaire surveys on tourist perceptions on insects and entotourism. Gunung Ledang was chosen as the research site for several reasons including the easy access to tourist respondents. Surveys showed that tourists are interested in insect. Supported by field observations and data collection, insects have potential to be excellent nature tourism product. Closer examination pointed out that insect groups that are reliable and visible are ants, butterflies, termites, dragonflies, moths, beetles, cicadas and damselflies. Field trials indicated that these insects were viable attractions as they are readily visible, safe, easily recognizable, with some having linkage to local culture. Regardless of the different environmental ambience, time of observation (except early mornings) and seasons, insect were always present. The tendency is there however, that particular environment such as water body (pool/waterfall) would attract certain insects such as odonates. Further surveys on tourists'

perception indicated that they supported entotourism and were willing to participate in one. As Gunung Ledang is a national and state park under the jurisdiction of the Perbadanan Taman Negara Johor (PTNJ), their staff would likely be the candidates as entotourism operators. Thus, this research also gauged the present level of understanding and knowledge on insects by PTNJ staff, supplemented by a training course. Statistically, there is significant increase in the understanding and knowledge of insects after the training. A small booklet was developed based on collections of insects from Gunung Ledang and used during the training. Although, much of the research is about evaluating the potential and viability of insects as tourism product, to diversify tourism products, in line with the Malaysia Government's agenda, it also pointed out the need to conserve Gunung Ledang (watershed with high ecological values and with cultural heritage)." (Authors)] Address: not stated

15241. Cuevas-Yáñez, K.; Rivas, M.; Muñoz, J.; Córdoba-Aguilar, A. (2015): Conservation status assessment of *Paraphlebia* damselflies in Mexico. *Insect Conservation and Diversity* 8: 517-524. (in English) ["(1.) We assessed the conservation status of the three Mexican *Paraphlebia* damselflies based on the criterion B of the Red List of the International Union for Conservation of Nature's (IUCN): *P. hyalina*, *P. quinta*, and *P. zoe*. According to this List, *P. hyalina* has not been evaluated, *P. quinta* appears as least concern, and *P. zoe* appears as Vulnerable. Geographical records were taken from literature, enquiries to specialists and field visits. We also projected the future potential geographical range area. (2.) We generated species distribution models (SDM) for *P. quinta* and *P. zoe* (as there were not enough records for *P. hyalina*) as a surrogate of the extension of occurrence (EOO) and also calculated the area of occupancy. Future distributions were projected for years 2020, 2050, and, 2080 based on predicted changes in climatic conditions. (3.) Species distribution models predicted current EOO areas for *P. quinta* and *P. zoe* as 18 860 and 16 440 km², respectively, and around 50% of their distribution coincides with agricultural, pasture or urban sites. (4.) Our SDM results indicate that IUCN-based conservation status of the three species should be changed as follows: *P. quinta* and *P. zoe* moved to endangered category, and *P. hyalina* to data-deficient category based on the reduced EOO areas and the historical loss of habitat. (5.) For *P. quinta*, future climatic projections suggest an initial reduction (2020) followed by an expansion (2050 and 2080) in suitable areas, whereas for *P. zoe* there will be a decrease in predicted area for the three time periods. Preserving areas that provide shade, high humidity and perching sites seems to be a key for *Paraphlebia* species survival." (Authors)] Address: Córdoba-Aguilar, A., Depto de Ecología Evolutiva, Instituto de Ecología, Universidad Nacional Autónoma de México, Apdo. Postal 70-275, Ciudad Universitaria, 04510, México, D. F., México. E-mail: acordoba@ecologia.unam.mx

15242. Curry, C.J.; Baird, D.J. (2015): Habitat type and dispersal ability influence spatial structuring of larval Odonata and Trichoptera assemblages. *Freshwater Biology* 60(10):

2142-2155. (in English) ["(1.) Freshwater invertebrate assemblages are believed to be structured by both local and larger scale processes (i.e. dispersal). In rivers, the extent to which dispersal processes influence local assemblage composition may depend on both the taxon and habitat in question. Poor dispersers should display greater spatial structuring than strong dispersers. Likewise, assemblages in poorly connected habitats should experience greater dispersal limitation, and therefore greater spatial structuring. (2.) We sought to test these hypotheses using two contrasting orders of aquatic insect, Odonata and Trichoptera. Odonata are believed to have greater dispersal capacity than Trichoptera. In river ecosystems, these orders inhabit both main channel habitats and more poorly connected riverine wetlands. Multi-habitat surveys of larval Trichoptera and Odonata assemblages were conducted at 34 sites in three 5th-order New Brunswick rivers. The degree of spatial and environmental structuring in assemblages was assessed using redundancy analysis-based variance partitioning. We also assessed the performance of different model-based spatial predictors (asymmetric eigenvector maps, AEMs and principal coordinates of neighbourhood matrices, PCNMs). (3.) For main channel areas, variance explained purely by environmental variables was greater for Odonata, while the purely spatial component of variance was greater for Trichoptera, regardless of the class of spatial descriptor. In riverine wetlands, both the purely environmental and purely spatial components of variance explained were similar or were greater for Trichoptera than for Odonata. (4.) The component of variance explained by spatial variables was greater in riverine wetlands than main channel areas for both Odonata and Trichoptera for most spatial descriptors, suggesting that taxa inhabiting riverine wetlands may experience greater dispersal limitation. However, the magnitude of this difference was relatively small in most cases. Eigenvector-based spatial descriptors (PCNMs, AEMs, netPCNMs) explained more variance than traditional spatial descriptors. For Trichoptera, network-based predictors (AEMs, netPCNMs) explained more variance than PCNMs in main channel areas. (5.) Our results suggest that dispersal ability and habitat type can influence the degree of spatial structuring in aquatic insect assemblages. However, these patterns must be investigated across a wider range of insect groups and at larger spatial scales. Our results also suggest that biomonitoring programs should consider assemblage spatial structure in building reference condition models and that aquatic conservation planners must consider the type and spatial arrangement of habitats in reserve design. Eigenvector-based spatial descriptors hold promise for interpreting biodiversity patterns in freshwater invertebrates, but more work is required to relate patterns to actual dispersal behaviour." 15243. David, S.; Ábelová, M. (2015): Vázky (Odonata) chrániého areálu Arboretum Mlyňany. *Folia faunistica*

Slovaca 20(2): 135-139. (in Slovakian, with English summary) ["Garden ponds are part of the area Mlynany Arboretum. In 2009 and 2011 a total of 277 specimens of dragonflies belonging to 11 species were collected in the 7 garden ponds. Four eudominant (*Ischnura elegans*, *Chalcolestes viridis*, *Sympetrum sanguineum* and *Coenagrion puella*), one dominant (*Erythromma viridulum*), four subdominant (*Somatochlora metallica*, *Anax imperator*, *Platycnemis pennipes*, *Ischnura pumilio*), one recedent (*Aeshna cyanea*) and subrecedent (*Libellula depressa*) could be distinguished. Dragonfly fauna of the studied garden ponds belong to the initial (pioneer) species colonizing the small man-made garden ponds. There were six autochthonous (*Platycnemis pennipes*, *Ischnura elegans*, *I. pumilio*, *Coenagrion puella*, *Erythromma viridulum* and *Anax imperator*) and one probably autochthonous (*Sympetrum sanguineum*) species found. All observed species we could associate with garden ponds." (Authors)] Address: David, S., ÚKE SAV, Akademická 2, SK-94901 Nitra, Slovakia. E-mail: stanislav.david@savba.sk

15244. De Knijf, G.; Demolder, H. (2015): Some dragonfly records from Albania, with *Cordulegaster heros* and *Somatochlora metallica* new for the country (Odonata: Cordulegasteridae, Corduliidae). *Libellula* 34(3/4): 181-185. (in English, with German summary) ["A total of 13 Odonata species were recorded during a short visit to Albania. Two species, *Cordulegaster heros* and *Somatochlora metallica*, are recorded for the first time for this country. One male of *C. heros* was observed on 21-vii-2015 on a small stream before ending up in the Mati River south of Klos. *Somatochlora metallica* was found on 24-vii-2015 at the glacial lake Buni Jezerce in the Prokletije Mountains in northern Albania, nearly at the border with Montenegro." 15248. De Marco, P.; Corrêa Nóbrega, C.; de Souza, R.A.; Neiss, U.G. (2015): Modeling the distribution of a rare Amazonian odonate in relation to future deforestation. *Freshwater Science* 34(3): 1123-1132. (in English) ["The advance of the deforestation frontier in the Amazon forest, the largest tropical forest and one of the richest ecosystems in the world, has threatened several plant and animal species. A

lack of good biogeographical information of their distributions and a shortage of basic knowledge on their ecology hinder the proper evaluation of the vulnerability of those species. We used species distribution modelling techniques to fill these gaps and to estimate the vulnerability of a forest-dwelling odonate endemic from the Amazon, *Diastatops nigra*. We used the MaxEnt algorithm and compared the efficiency of this method in relation to the type of environmental data set (climate-only and climate+hydrographic environmental variables). We also estimated the decrease in extension of occurrence of *D. nigra* in relation to a recently developed model for future deforestation also produced with the MaxEnt approach. Predicted suitable areas were isolated patches in the central Amazon and many peripheral areas. In general, those areas had stable climates with low seasonality in rainfall. The Amazon deforestation frontier is expanding mainly from the south. The core area of *D. nigra* distribution is in the central Amazon, so in the short-term projection, the main threat for this species was not the deforestation itself. However, deforestation may extirpate some peripheral populations of this species and increase isolation among those patches of suitable areas. We suggest the use of this model for prioritizing future odonate inventories targeting the other species of the group." 15249. Debecker, S.; Sommaruga, R.; Maes, T.; Stoks, R. (2015): Larval UV exposure impairs adult immune function through a trade-off with larval investment in cuticular melanin. *Functional Ecology* 29(1): 1292-1299. (in English) ["Despite the strong impact of ultraviolet (UV) radiation on invertebrates, it is unknown whether it affects immune function across metamorphosis. More generally, the mechanisms on how larval stressors bridge metamorphosis and shape adult fitness in animals with a complex life cycle remain poorly understood. We studied whether cuticular melanin content is upregulated under UV exposure in the larval stage of the damselfly *Coenagrion puella* and whether this is traded off across metamorphosis against a key component of the invertebrate immune response, the melanotic encapsulation response, in the adult stage. Larvae exposed to UV increased the melanin content in their exoskeleton and metamorphosed later and at a smaller mass than animals reared without UV. Across metamorphosis, this was associated with a reduced melanotic encapsulation response, thereby constituting the first proof for a UV driven impaired immune response in an invertebrate. The demonstrated costs of UV exposure in terms of age and mass at metamorphosis and reduced adult immune response likely translate into reduced adult fitness. Path analysis indicated that the immunosuppressive property of larval UV exposure was not mediated by age and mass at metamorphosis, but instead that the adult immune response was traded off against larval cuticular melanin investment. Melanin-based trade-off across metamorphosis provide a new pathway by which effects of larval stressors are carried over to the adult stage and thereby advances our understanding of the still

largely enigmatic mechanisms of carryover effects of larval stressors across metamorphosis. Given the mechanistic base, this carryover effect of larval UV exposure on adult immune function is expected to be general and may constitute a widespread and important cost of UV exposure in invertebrates." 15250. Denhoff, L.A. (2015): Microhabitat occupancy, distribution, and selection by *Cordulegaster diastatops* (Selys, 1854) (Odonata: Cordulegastridae) in seeps and springs of Madison County, New York. M.Sc. thesis, Environmental and Forest Biology, State University of New York College of Environmental Science and Forestry: 67 pp. (in English) ["Suitable microhabitat availability for dragonfly larvae within a lotic environment influences the distribution and abundance of individuals, yet few studies have addressed this. The objective of this study was to determine how nine microhabitat variables influenced *Cordulegaster diastatops* occupancy within two field sites, as well as to determine if larval dragonflies have the ability to select a characteristic of their microhabitat. Microhabitat variables differed between Nelson Swamp Unique Area (NSUA) and Tioughnioga Wildlife Management Area (TWMA), as well as between occupied and unoccupied sites within NSUA only. NSUA appears to be more suitable for *C. diastatops* than TWMA. Relatively shallow water depth, low water temperature, and slow water velocity along with a substrate that larvae can burrow in are associated with larval presence. In a sediment choice experiment larvae demonstrated the ability to select a substrate type, and most larvae exhibited a preference for fine sand over mixed gravel." (Author)] Address: not stated

15251. Derso, S.; Beyene, A.; Getachew, M.; Ambelu, A. (2015): Ecological status of hot springs in eastern Amhara region: Macroinvertebrates diversity. *American Scientific Research Journal for Engineering, Technology, and Sciences* 14(2): 1-22. (in English) [Ethiopia, "Springs are the places where ground water is discharged at specific locations. They vary dramatically as to the type of water they discharge. Hot springs is having the temperature of the water lies significantly above the mean of annual air temperature of that region. Temperature is one of the most important factors that govern species abundance and distribution. The objective of this study is to examine the relationship between biological parameters (macroinvertebrate diversity) with physicochemical water and habitat quality of hot springs in Easter Amhara Region. A cross-sectional study of physical, chemical and biological components of the hot springs was carried out to assess their ecological status. Samples were collected from March to May 2013. Biological samples were collected to provide a qualitative description of the community composition at each sampling site. Water samples were collected for analysis of selected physicochemical parameters following water quality assessment protocols. A total of 1095 macroinvertebrates classified into

10 orders and 31 families of macroinvertebrates were collected from the 12 sampling sites. The most abundant orders were Diptera 49.90%, Odonata 15.53%, Coleoptera 12.97%, and Ephemeroptera 9.5% represented by 14 families. Macroinvertebrate taxa were absent at B1 and H1 sites with the temperature of 72 °C and 70 °C respectively. However, in this study, the macroinvertebrate taxa (Chironomidae and Hydrobiidae) were found within a temperature of 52 °C at S1 and H1 sites. The results are also revealed that as the temperature gradient declines, the macroinvertebrate diversity flourished. Due to this fact, both macroinvertebrate diversity and family biotic index were negatively correlated with temperature and the correlations were significant. Human disturbance and habitat conditions varied considerably among sites in the study area. Although human disturbance and water pollution are among the factors influencing ecological quality, the strong correlations between water temperature and species diversity suggest that temperature is the major environmental gradient affecting aquatic biodiversity in hot springs." 15252. Dijk, B.; Laurila, A.; Orizaola, G.; Johansson, F. (2015): Is one defence enough? Disentangling the relative importance of morphological and behavioural predator-induced defences. *Behavioral Ecology and Sociobiology* 70(2): 237-246. (in English) ["Many organisms show predator-induced behavioural and morphological phenotypic plasticity. These defence mechanisms are often expressed simultaneously. To estimate the relative importance of these two defences, we conducted a laboratory experiment using tadpoles of the common frog (*Rana temporaria*) as prey and *Aeshna* dragonfly larvae as predators. We first raised tadpoles in the presence and absence of caged predators to induce differences in defensive morphology, and then conducted free ranging predator trials in environments that were either with or without the presence of predation cues to induce differences in defensive behaviour. This 2 × 2 design allowed us to separate the effects of inducible morphology from inducible behaviour. Caged predators induced deeper bodies and tailfins and reduced activity levels in tadpoles. The time to first capture was shortest in tadpoles without morphological or behavioural defences. Tadpoles with a behavioural defence had a significantly longer time to first capture. Tadpoles with only antipredator morphology tended to have a longer time to first capture as compared to those without any induced defences. This treatment also had a higher number of injured tadpoles as compared to other treatments, suggesting that inducible morphology facilitates predator escape due to the 'lure effect'. However, tadpoles with both behavioural and morphological defences did not have a longer time to first capture as compared to tadpoles with only morphological or behavioural induced defences. Our results suggest that both behavioural and morphological antipredator responses contribute to reduced capture efficiency by predators, but their simultaneous expression did not have any additive effect to the time

of first capture and survival, and that the morphology response is most effective when tadpoles are active." (Authors)] Address: Johansson, F., Dept of Ecology & Environmental Science, Animal Ecology Group, Umea Univ., 90187 Umea, Sweden. E-mail: frank.johansson @eg.umu.se

15253. Dimapinto, F.A.; Nuneza, O.M.; Villanueva, J.T. (2015): Species diversity of adult Odonata in selected areas of Lanao Del Sur, Philippines. *Journal of Biodiversity and Environmental Sciences* 7(4): 200-210. (in English) ["Field work in selected areas in Lanao del Sur was conducted to determine the Odonato fauna present in the area. Adult Odonata samples were collected using sweep netting and handpicking methods from four sampling sites. Biodiversity indices, similarity index, and canonical correspondence analysis were determined using Paleontological Statistics Software Package (PAST) version 2.17c. Twenty-one species (10 damselflies and 11 dragonflies) were documented with relatively low endemism of 42.86%. High relative abundance of 37.28% was observed in site 4. Sites 1 and 3 were observed to have high species diversity while sites 2 and 4 had moderate species diversity. There was a more or less even species distribution in the areas sampled. Dominance of *Pseudagrion pilidorsum pilidorsum* was recorded in Marawi City. Canonical correspondence analysis showed that environmental factors such as elevation, air temperature and relative humidity affect the abundance of species. It appears that human-induced activities limit the occurrence and abundance of the Odonata, especially the endemic species." 15254. Domeneghetti, D.; Mondini, S.; Carchini, G. (2015): Odonata species richness in the Castelporziano presidential estate, present and past. *Rendiconti Lincei* 26, Supplement 3: 367-377. (in English) ["The Castelporziano estate, a former game reserve along the Tyrrhenian coast near Rome, is a conserved patch of pristine woodland, in which several species of the Odonates breed in numerous small ponds and a few rivulets. The odonate species of Castelporziano have been recorded since the 1930s, with an in-depth survey carried out in 1997–1998. The present, additional survey on the odonate species of Castelporziano aims at contributing to long-term ecological research, by assessing variations in odonate fauna up to the present, and linking them to environmental changes. The presence of adult Odonata species was assessed in the field by two observers at 20 water bodies (ponds and other sites) from mid-March to early November 2012. The presence of shade, riparian and submerged vegetation, fish and the number of drying-up events during the past decade were also recorded. Results showed a small reduction in the number of odonate species for the entire estate, with several qualitative changes in comparison with previous data. On the contrary, a site-specific analysis of changes from 1997–1998 to 2012 revealed a significant considerable reduction in the average number of species. This was linked to a decrease in

riparian and submerged vegetation. Drying-up events did not appear to be a crucial factor, and fish and shade were essentially unchanged. In conclusion, the Castelporziano water environment seems to have deteriorated, probably as a consequence of the trampling by wild ungulates in woodland ponds." 15257. Drury, J.P.; Anderson, C.N.; Grether, G.F. (2015): Seasonal polyphenism in wing coloration affects species recognition in rubyspot damselflies (*Hetaerina* spp.). *Journal of Evolutionary Biology* 28(8): 1439-1452. (in English) ["Understanding how phenotypic plasticity evolves and in turn affects the course of evolution is a major challenge in modern biology. By definition, biological species are reproductively isolated, but many animals fail to distinguish between conspecifics and closely related heterospecifics. In some cases, phenotypic plasticity may interfere with spe-

cies recognition. Here, we document a seasonal polyphenism in the degree of dark wing pigmentation in smoky rubyspot damselflies (*Hetaerina titia*)—a shift so pronounced that it led early researchers to classify different forms of *H. titia* as separate species. We further show how the seasonal colour shift impacts species recognition with the sympatric congener *H. occisa*. Interspecific aggression (territorial fights) and reproductive interference (mating attempts) are much more frequent early in the year, when *H. titia* more closely resembles *H. occisa*, compared to later in the year when the dark-phase of *H. titia* predominates. Using wing colour manipulations of tethered damselflies, we show that the seasonal changes in interspecific interactions are caused not only by the seasonal colour shift but also by shifts in discriminatory behaviour in both species. We also experimentally tested and rejected the hypothesis that learning underlies the behavioural shifts in *H. occisa*. An alternative hypothesis, which remains to be tested, is that the seasonal polyphenism in *H. titia* wing coloration has resulted in the evolution of a corresponding seasonal polyphenism in species recognition in *H. occisa*. This study illustrates one of the many possible ways that plasticity in species recognition cues may influence the evolution of interspecific interactions." 15258. DuBois, R. (2015): Detection probabilities and sampling rates for Anisoptera exuviae along river banks: influences of bank vegetation type, prior precipitation, and exuviae size. *International Journal of Odonatology* 18(3): 205-215. (in English) ["Exuviae collections have considerable value in population studies of Odonata, but methods for standardizing collections or estimating densities and detection probabilities have been little studied. I measured sampling rates for Anisoptera exuviae and used a maximum likelihood, four-pass, depletion population estimator to standardize collections and to estimate exuvial densities and detection probabilities along 10 riverbank stations in Wisconsin. First-pass sampling rates averaged slower than the overall average for experienced collectors (0.53 m min⁻¹ compared to 0.90 m min⁻¹) because more exuviae were present on the first pass, increasing picking and handling time. Neither bank vegetation type (grassy versus forested) nor amount of prior precipitation affected sampling rate. Exuviae detection probabilities for a single pass ranged from 0.49 to 0.75, and averaged 0.64. The mean cumulative probability of detection increased to 0.87 after two passes, 0.95 after three passes, and 0.98 after four passes. A strong negative relationship existed between detectability and the amount of prior precipitation. Bank vegetation type did not affect detection probability. Smaller exuviae had an 8% lower probability of detection than larger exuviae. If four sampling passes are cost-prohibitive for some exuviae studies, making just two passes may provide an adequate estimate of sampling efficiency. The assumption that exhaustive collecting efforts will find all or most of the exuviae

along vegetated natural banks is unfounded." (Author)] Address: DuBois, R., Department of Natural Resources, Bureau of Natural Heritage Conservation, 1701 N. 4th St., Superior, WI 54880, USA

15259. DuBois, R.B.; Tennessen, K.T. (How did E. M. (2015): Walker measure the length of the labium of nymphs of *Aeshna* and *Rhionaeschna* (Odonata: Aeshnidae)?): The Great Lakes Entomologist 48(1-2). 79: 92. (in English) ["The exhaustive studies of nymphs of *Aeshna* Fabricius and *Rhionaeschna* Förster by E. M. Walker (1912-1958) have long guided the taxonomy of these groups and formed the basis for keys still in use today. However, uncertainty about how he measured the length of the labium, including the varied terminology he used over the duration of his career concerning this structure, has led to confusion about application of his taxonomic recommendations. We recalculated ratios of the maximum width/length $W(\max)/L$ by measuring the illustration dimensions of folded labia and prementums in publications throughout his career and compared these data with the ratios he stated in those publications and with ratios derived from measurements of specimens in our collections. Our results show that from 1912 to 1941, Walker restricted length measurement to the prementum proper (which he called the "mentum of the labium"), exclusive of the ventrally visible portion of the postmental hinge. However, in 1941 he reported ratios from length measurements done two ways, excluding the postmental hinge in his description of the nymph of *A. verticalis* Hagen, but including the hinge in his description of the nymph of *A. septentrionalis* Burmeister (Whitehouse 1941). In Walker's most recent and influential work (1958), he included the postmental hinge in labium length measurements of nine species, but restricted length measurements to the prementum for five others. He was consistent with the use of terms, using both "folded labium" by which he meant the prementum plus the postmental hinge, and "prementum" by which he meant only that structure. However, Walker's descriptions of the labium in his latest work are buried in long, frequently punctuated sentences that for most species include the terms "folded labium" and "prementum" in the same sentence, so careful reading is required to know which term is intended in the width/length ratio. Width/length ratios we each calculated independently were invariably similar for a given species and were usually similar to Walker's stated ratio for that species. These similarities affirm our conclusion that while labium measurements must be done with care, they are closely repeatable among workers and will consistently lead to correct determinations in properly designed couplets of dichotomous keys to these genera. We recommend measuring the length of the prementum proper in future studies of these genera when labium ratios are calculated because we found less variability in those cases than when the measurements included the postmental hinge. An approximate conversion between the two methods of calculating $W(\max)/L$ ratios can be made as follows: ratio calculated when the length of the prementum excluding the postmental hinge is used $\times 0.88$ is approximately equal to the ratio when the postmental hinge is included for

species of *Aeshna* and *Rhionaeschna* in North America." (Authors)] Address: DuBois, R., Wisconsin Department of Natural Resources, 1401 Tower Ave., Superior, WI 54880, USA. E-mail: robert.dubois@Wisconsin.gov

15260. Durand, E.; Rigaux, J. (2015): Further additions to the knowledge of the odonate fauna of Armenia, with first record of *Pantala flavescens* (Odonata: Libellulidae). *Notulae odonatologicae* 8(6): 184-190. (in English) ["As result of two targeted surveys of the Armenian odonate fauna in August 2010 and June 2014 a male *Pantala flavescens* was recorded photographically on the shore of Lake Sevan in the Gegharkunik district, representing the first record for Armenia. *Leucorrhinia pectoralis* was rediscovered at Javakheti-Shirak volcanic plateau (Armenian highland) 75 years after the species was first reported for Armenia. Data on the first evidenced reproduction of *Coenagrion armatum* were also collected." (Authors)] Address: Durand, E., Château Vilain RN7 13410 Lambesc, France. E-mail: mr.oizo3@gmx.fr

15261. Ebert, M.; Kölbl-Ebert, M.; Lane, J.A. (2015): Fauna and predator-prey relationships of Ettliling, an Actinopterygian fish-dominated Konservat-Lagerstätte from the Late Jurassic of southern Germany. *PLoS ONE* 10(1): e0116140. doi:10.1371/journal.pone.0116140: 33 pp. (in English) ["The newly recognized Konservat-Lagerstätte of Ettliling (Bavaria), field site of the Jura Museum Eichstätt (JME), is unique among Late Jurassic plattenkalk basins (Solnhofen region) in its abundant, extremely well preserved fossil vertebrates, almost exclusively fishes. We report actinopterygians (ginglymodins, pycnodontiforms, halecomorphs, aspidorynchiforms, "pholidophoriforms," teleosts); turtles; and non-vertebrates (echinoderms, arthropods, brachiopods, mollusks, jellyfish, sponges, biomats, plants) in a current faunal list. Ettliling has yielded several new fish species (*Bavarichthys incognitus*; *Orthogonikleithrus hoelli*; *Aspidorhynchus sanzenbacheri*; *Macrosemimimus fegerti*). Upper and lower Ettliling strata differ in faunal content, with the lower dominated by the small teleost *Orthogonikleithrus hoelli* (absent from the upper layers, where other prey fishes, *Leptolepides* sp. and *Tharsis* sp., occur instead). Pharyngeal and stomach contents of Ettliling fishes provide direct evidence that *Orthogonikleithrus hoelli* was a primary food source during early Ettliling times. Scarcity of ammonites and absence of vampyromorph coleoids at Ettliling differ markedly from the situation at other nearby localities in the region (e.g., Eichstätt, Painten, Schamhaupten, the Mörsheim beds), where they are more common. Although the exact biochronological age of Ettliling remains uncertain (lack of suitable index fossils), many Ettliling fishes occur in other plattenkalk basins of Germany (e.g., Kelheim) and France (Cerin) dated as Late Kimmeridgian to Early Tithonian (eigeltlingense horizon), suggesting a comparable geologic age. The Ettliling deposits represent an independent basin within the larger Upper Jurassic "Solnhofen Archipelago", a shallow subtropical sea containing scattered islands, sponge-microbial and coral reefs, sandbars, and deeper basins on a vast carbonate platform along the northern margin of the Tethys Ocean." 15262. El Haissoufi, M.; De Knijf, G.; van't Bosch, J.; Benas, N.; Millán Sánchez, A. (2015): Contribution to the knowledge of the Moroccan Odonata, with first records of *Orthetrum sabina*, and an overview of first and last dates for all species. *Odonatologica* 44(3): 225-254. (in English) ["Several field surveys between 2007 and 2014 were undertaken in Morocco. Altogether 54 species were observed during our studies, representing 86 % of the odonate fauna of the country. *Orthetrum sabina* is new for Morocco, increasing the number of species to 63. The species was found at Oued Ez-Zahar near Akhfenir, about 1 700 km off its nearest known locality at Ouargla in Algeria. Two small populations of *Erythromma viridulum* were found for the first time in the Rif, bridging the gap between populations in the Middle Atlas and the Iberian Peninsula. The third observation of *Sympetrum sinaiticum* for Morocco was recorded and we were able to significantly increase the known number of localities of the threatened Moroccan endemic *Cordulegaster princeps*. We further can show that several species (e.g., *Boyeria irene*, *Pyrrhosoma nymphula*) are more widely distributed than believed and occur also at low altitudes in the country. On the other hand, *Calopteryx exul*, *Calopteryx virgo meridionalis*, *Lestes dryas*, *Coenagrion mercuriale*, *Aeshna isoceles* and *Libellula quadrimaculata* are very rare in Morocco and their populations should be monitored to assess their potential decline. Finally, for all Moroccan dragonfly species the first and last observation dates are listed. For 17 of them we provide the earliest observation date and for seven species we prolong the observation period." 15265. Endersby, I.; Fliedner, H. (2015): The naming of Australia's dragonflies. Busybird Publishing, PO Box 855, Eltham Victoria, Australia 3095: VII + 278 pp. (in English) [Review of Albert Orr [agorr@bigpond.com]: "Formal zoological nomenclature follows the binomial system of genus and species originally established by the Swedish biologist Carl Linné, or Linnaeus, in his *Systemae Naturae* of 1758. In principle any animal can be uniquely identified in this way, with the genus invariably being a noun, and the species an adjective or another noun which qualifies the genus. The language chosen for this nomenclature was Latin, at that time the universal language of science, understood by all educated people. Equally important was Classical Greek in its Latinised form. With changing educational practices, knowledge of even basic Latin has become comparatively rare, knowledge of Greek even more so, hence the scientific names of animals and plants learned by modern biology students have become totally divorced from any meaning, especially among native English speakers and speakers of non-European languages. Whereas Linnaeus' contemporaries would have recognised the gods, demi-gods and heroes of Classical mythology and literature, the modern Lep-

idopterist who cares to read Homer's *The Iliad* or *The Odyssey*, finds a *dramatis personae* consisting entirely of familiar Swallowtail and Morpho butterflies. In recent times there has been a virtual plethora of books attempting to explain the meanings of Latin and Greek-based Latin names. Many, such as *Latin for Bird Lovers* (Lederer & Burr, 2014) or *The Naming of the Shrew* (Wright, 2014), attempt to entertain as much as to instruct, producing a final result which is somewhat frothy and short on detail. Fortunately odonatologists have been rather better served by scholarly articles explaining the meanings and origins of dragonfly and damselfly scientific names (e.g. Fliedner 1997, 2006, Endersby 2012) and now these two authors have joined forces to produce 'The Naming of Australian Dragonflies'. This volume, a substantial tome of xiii +278 pages in octavo format, gives us the most comprehensive account we might wish for on the origins and meanings of every available species-group or genus-group name for Australia's dragonflies. These include not only the ca 324 accepted species names and 106 genus names, as well as species such as *Rhinocypha tinctoria* and *Neurobasis australis* which are not reliably recorded from Australia and are retained in faunal lists out of sheer obstinacy, but also all available synonyms and homonyms, of which there are more than a few. The book begins with a brief account of the history of the naming of the Australian Odonata, a brief introduction to Latin and Greek prefixes and suffixes and the declensions of the latter and a general discussion of where names come from (people, places, appearance; including colour, pattern, size etc.). There is a detailed tabular breakdown by taxon author of eponyms (named after people, real or legendary) and toponyms (named after a place). The most valuable part of this chapter is the grammatical section. With the odd lapsus (e.g. the topographic suffix, -ensis should be declined: -ensis, -ensis, -ense) this section provides an admirable introduction to the Latin grammar and Greek orthography and the rules for transliteration from Greek to Roman script that are needed to understand how names are formed and modified under gender agreement requirements. I certainly learned a great deal from reading it and while readers unfamiliar with Latin or Greek might find it heavy going, a little effort taken to master these basic rules and to learn the Greek alphabet will be repaid with interest by affording a full understanding of the detailed etymologies which come later. The next chapter provides engaging and interesting biographies of the 41 individuals who have authored or co-authored an Australian dragonfly genus or species name. These are admirable in their detail, and are generally accompanied by a thumbnail black and white portrait, allowing us to put a face to the name, and serve the very useful purpose of demystifying nomenclature. These names were bestowed by flesh and blood human beings who lived on average a respectable 71.5 ± 11 years, apart from the six who are still with us. Indeed even in cases where I have been long acquainted with the individuals concerned I learned several diverting facts. Quite a few of my own cohort can empathise directly with Günther Theischinger whose first class education led initially to employment on the railways. The next and largest

chapter deals with the individual etymologies of every available species-group or genus-group name ever given to an Australian dragonfly. It is well researched, erudite and complete. Where necessary, extracts from original descriptions in their original language are included (with English translations for non-English texts). For those of us attempting to construct generic names of odonates, this section has much information of relevance far beyond the Australian fauna. It has been a custom among odonatologists to use Greek roots when naming genera and Latin for species-group names. Generally Latin is fairly accessible using a good dictionary, but Greek is a completely different proposition. Even with the fattest Lexicon available a lot of background knowledge is needed to tease out the component roots and it is not difficult to completely misunderstand them. The etymologies in this book do the work for us. Anyone studying dragonfly nomenclature working in any region will find their knowledge vastly expanded and deepened by studying these examples. Of course as earlier authors rarely explained their sources there remain unresolved mysteries and educated guesses. Why did Fabricius write *Aeshna*, not *Aeschna* for example? The authors' explanation that this might have come from him adopting an English style of spelling is the most convincing argument I have heard yet. I was particularly taken by the conjectured meaning for *Aethriamanta* – loving the bright sky. I disagree that *Rhythymis Braganza* should be regarded as *incertae sedis* (see p. 11, 123, 268) but rather agree with Hämäläinen (2015) that it was named after a Brazilian monarch as a result of a comedy of errors. This however is the only point of difference I can find in the entire book. Some names simply defy decoding – the meanings of both generic and specific names of the common and widespread *Tholymis tillarga* remain unknown. The book includes an extensive main bibliography of 274 entries, in addition to subsidiary reference lists totalling about 150 items in earlier sections. It is rounded off by five appendices, the first three giving comprehensive statistics on authorship and details of the categorisation of names. The most valuable are Appendix four, which establishes the gender of all generic names and Appendix five which gives the rules for transliteration from Greek to the Roman alphabet. I thought I knew these rules, but in fact several important gaps in my knowledge were exposed and have now been filled. In summary, to anyone with a special interest in zoological etymology or anyone actively involved in zoological nomenclature (i.e. naming new species) I cannot recommend this book too highly. It is well researched, erudite and thorough, with a relevance well beyond Australian shores. Both authors are to be warmly congratulated for having produced such an impressive, informative and useful piece of scholarship."] Address: Endersby, I., 56 Looker Rd, Montgomery, Victoria 3094, Australia. 15266. Farkas, A.; Mero, T.O.; Mora, A. (2015): Contribution to the Odonata fauna of the Lake Velencei. *Acta Biol. Debr. Oecol. Hung.* 33: 111-123. (in Hungarian, with English summary) ["Faunistical study on odonates was carried out in the Natura 2000 area of Lake Velencei, with a main focus

on the species of community interest. In 2013 at 58 sampling sites 2270 individuals (133 larvae, 638 exuviae and 1499 adults) representing 24 species were collected or observed. The number of species per sampling site ranged from one to 15, with a mean of six species. Six species (*Anax parthenope*, *Cordulia aenea*, *Somatochlora flavomaculata*, *Libellula fulva*, *Orthetrum albistylum*, *Sympetrum fonscolombii*) were first recorded from the territory of the lake. Surprisingly, two of them (*A. parthenope*, *C. aenea*) were among the most frequent species as well. During our study one Natura 2000 species, *Leucorrhinia pectoralis* was found, which is strictly protected in Hungary. Though a low number of adults of this species were observed, the presence of a breeding population was proved by the occurrence of larvae, which were first collected from the lake. Further three species (*Aeshna isosceles*, *S. flavomaculata*, *L. fulva*) are protected in Hungary, among them *A. isosceles* was frequent. Conservation of the mosaic habitats of the Natura 2000 area is essential to preserve the populations of the protected species, especially that of *L. pectoralis*." (2015): Local extinctions and range contraction of the endangered *Coenagrion mercuriale* in North Africa. *International Journal of Odonatology* 18(2): 137-152. (in English) ["Freshwater biodiversity is currently threatened worldwide. In North Africa, 24.4% of Odonata are regionally threatened with extinction. In this region, freshwater resources are particularly scarce and an increasing shortage of water is expected. To better understand the current threats to the endangered North African damselfly *Coenagrion mercuriale* we updated information on extinct and extant populations in North Africa and characterized these localities with regard to their topography, climate and anthropogenic use (anthrome). The *C. mercuriale* populations are being lost and this damselfly is experiencing range contraction. In Morocco nearly 45% of the populations have become extinct in recent decades and in Tunisia a single extant population remains. This species, which occupied predominantly areas of high value for human settlement, is now mainly restricted to high altitude areas. Nevertheless, the extant populations remain under threat of extinction due to increasing demand for water, changes in agricultural practices and land conversion." 15268. Flechoso, M.F.; Morales, J.; Lizana, M.; González, I. (2015): Taking advantage of the massive emergence of the odonate *Sympetrum flaveolum* as a trophic resource for *Zootoca vivipara*. *Bol. Asoc. Herpetol. Esp.* 26(1): 23-26. (in English) ["In the present work our observations were made

in the municipality of Cervera de Pisuerga (Palencia, North Spain) around two small ponds located in the Natural Park of Fuentes Carrionas-Fuente Cobre, (1660 masl). The UTM grid (Datum ETRS89) is 30T UN66. The habitat was a bog without medium-tall shrubs and abundant clumps of sphagnum (peat moss), grasses and *Erica tetralix*. Most specimens were found at a distance of less than 10 m from water surface. In August 2014, we observed several adult specimens of *Z. vivipara* of which at least two (a male and a female) were feeding on teneral of *S. flaveolum*. At the same time, a massive emergence of teneral resting on the surrounding vegetation was taking place. This predatory behaviour was observed over approximately 2 h. The fact that *Z. vivipara* predate on this Odonata is interesting since predation on dragonfly imagoes by this species of lizard was not previously reported." 15269. Frati, F.; Piersanti, S.; Conti, E.; Reborá, M.; Salerno, G. (2015): Scent of a dragonfly: Sex recognition in a polymorphic coenagrionid. *PLoS ONE* 10(8): e0136697. doi:10.1371/journal.pone.0136697: 14 pp. (in English) ["In polymorphic damselflies discrimination of females from males is complex owing to the presence of androchrome and gynochrome females. To date there is no evidence that damselflies use sensory modalities other than vision (and tactile stimuli) in mate searching and sex recognition. The results of the present behavioural and electrophysiological investigations on *Ischnura elegans*, a polymorphic damselfly, support our hypothesis that chemical cues could be involved in Odonata sex recognition. The bioassays demonstrate that males in laboratory prefer female to male odour, while no significant difference was present in male behaviour between stimuli from males and control. The bioassays suggest also some ability of males to distinguish between the two female morphs using chemical stimuli. The ability of male antennae to perceive odours from females has been confirmed by electrophysiological recordings. These findings are important not only to get insight into the chemical ecology of Odonata, and to shed light into the problem of olfaction in Paleoptera, but could be useful to clarify the controversial aspects of the mating behaviour of polymorphic coenagrionids. Behavioural studies in the field are necessary to investigate further these aspects." 15270. Fredregill, C.L.; Mottl, G.C.; Dennett, J.A.; Bueno Jr., R.; Debboun, M. (2015): Efficacy of two Larvasonic™ units against *Culex* larvae and effects on common aquatic nontarget organisms in Harris County, Texas. *Journal of the American Mosquito Control Association* 31(4): 366-370. (in English) ["The Larvasonic™ Field Arm Mobile Wetlands Unit and SD-Mini were tested for efficacy against *Culex* larvae, and effects on aquatic nontarget organisms (NTO). The Field Arm provided 84.61% to 100% control of caged

Culex larvae out to 0.91-m distance in shallow ditches and 60.45% control of Culex larvae at 0.61-m without any effects to caged NTO. Slow ditch treatment achieved 77.35% control compared to fast treatment (20.42%), whereas 77.65% control was obtained along edges of a neglected swimming pool, compared to near the middle (23.97%). In bucket tests, the SD-Mini provided >97% control of Culex and 85.35% reduction of immature giant water bugs, which decreased slightly (83.45%) over the monitoring period, which was not significantly different from cannibalistic damselflies (62.80%), with reduction of both being significantly higher than other NTO tested. There was a small (0.37%) reduction of dragonflies (naiads), due to cannibalism. Both Larvasonic units could effectively augment conventional larvicide operations in smaller areas without causing resistance within mosquito populations or harming NTO when used properly." 15271. Frobel, K.; Schlumprecht, H. (2015): Untersuchungen zur Substrat- und Habitatwahl von *Cordulegaster bidentata* im Landkreis Nürnberger Land (Odonata: Cordulegasteridae). *Libellula* 34(1/2): 3-26. (in German, with English summary) ["Investigations regarding substrate and habitat choice of *Cordulegaster bidentata* in the Nürnberger Land district, Bavaria (Odonata: Cordulegasteridae) – In a survey of 486 forest streams within an area of 400 km² in the east of the rural district "Nürnberger Land", Bavaria, larvae and / or imagines of *C. bidentata* were recorded at 148 single springs. The occurrence of *C. bidentata* concentrated in the beech forests at the spring rich slopes of the Frankonian Alb ("Albtrauf") on calciferous springs in White Jurassic or in a transitional layer between White Jurassic and Dogger ("Ornatenton"). The district turned out to be one of the most important areas of *C. bidentata* within Bavaria. Semiquantitative surveys (mainly in potholes) from all springs revealed only one very large occurrence, five large occurrences, five of middle scale, and many low (n = 47) to very low (n = 55) scaled occurrences of larvae. A statistical analysis of substrate and habitat factors as well as the calculation of probability of occurrence at colonized springs reveals the relative importance of habitat factors. Thus, *C. bidentata* prefers springs with high coverage of the curled hook-moss *Palustricola commutata* or other mosses, chalky detritus (spherical chalk concretions) and deadwood. Furthermore, springs with sinter and small deadwood are preferred as well as springs with little human impact, complex spring systems with several neighbouring springs and springs with moderate flow velocity and medium flow rate. Rivulet stretches of 200 to 300 m are significantly preferred whereas stretches shorter than 50 m are avoided. Deadwood plays an essential role in larval occurrence by building stepping structures causing the formation of potholes with detritus coverage and reducing flow velocity within the rivulets. Only about half of the springs located in forests within the survey area are in semi-natural conditions. Only a very small part of the springs is located in strictly protected areas. High land use

pressure and frequent drying processes caused by climate change severely endanger near-natural springs nowadays and in the near future. Hence, it is strongly recommended to keep *C. bidentata* under its current red list status." 15272. Furness, A.N.; Soluk, D.A. (2015): The potential of diversion structures to reduce roadway mortality of the endangered Hine's emerald dragonfly (*Somatochlora hineana*). *Journal of Insect Conservation* 19(3): 449-455. (in English) ["Roadways near wetlands and ponds inflict high roadkill rates on a wide variety of taxa. For threatened or endangered species that typically do not have large adult populations, fast reproduction rates, and/or rapid recolonization rates, such mortality is likely to have significant population consequences. Thus, exploring ways to reduce roadkill rates will have considerable conservation benefits. In this study, we evaluate whether a diversion structure can be used to modify flight behaviour of the endangered *S. hineana* in ways that would reduce roadway mortality. Flight behaviour of adult *S. hineana* was observed with and without two 3 m high nets spaced at 6 and 12 m to simulate a small and a larger roadway. The netting significantly deterred ($p < 0.0001$) *S. hineana* adults from crossing the simulated roadway. Flight height was also influenced significantly ($p = 0.0025$) with flight heights over the 6 m net spacing being higher than those over the 12 m spacing. This study suggests that the use of diversion netting in areas where sensitive dragonfly species interact with motor vehicles might aid in reducing roadway mortality and might help reduce the overall impact of roadways on wetland ecosystems." (Authors)] Address: Soluk, D.A., Dept of Biology, University of South Dakota, 414 E. Clark Street, Vermillion, SD, 57069, USA. E-mail: daniel.soluk@usd.edu

15273. Gallesi, M.M.; Sacchi, R.; Hardersen, S.; (2015): Does wing shape of andromorph females of *Calopteryx splendens* (Harris, 1780) resemble that of males? *International Journal of Odonatology* 18(4): 305-315. (in English) ["Female limited polymorphism consists in the coexistence of two or more female morphs in the same population and is widespread among odonates. Generally, one female morph, the andromorph, resembles males in colour or, sometimes, also in morphology and behaviour, while one or more other morphs, gynomorphs, differ from males. This phenomenon is probably promoted by advantages to females which arise from reduced sexual harassment. Andromorph females of *C. splendens* keep wing spots, like males (although these ornaments do not match exactly male wing spot colour), while gynomorphs have hyaline wings. Males and gynomorphs show a marked sexual dimorphism in wing shape, and this determines flight patterns which differ between sexes. If andromorphs mimic male wing spots to avoid harassment, they may also benefit from mimicking the male flight morphology, and consequently the male flight pattern. In this case wing shape of andromorph and gyno-

morph females would differ, as the wing shape of andromorphs resembles that of males. In this study we compared the wing morphology of males and of the two female morphs of *C. splendens* using geometric morphometrics. Our results revealed that andromorphs and gynomorphs of this species share the same wing shape, size, and static allometry, and this suggests that flight patterns should also be shared by the two morphs. Thus, females might avoid male harassment by mimicking exclusively male wing pigmentation (male mimicry hypothesis), or confound males through an uncommon appearance (learned mate recognition hypothesis)." 15274. Gallesi, M.M.; Mobili, S.; Cigognini, R.; Hardersen, S.; Sacchi, R. (2015): Sexual dimorphism in wings and wing bands of *Sympetrum pedemontanum* (Müller in Allioni 1776). *Zoomorphology* 134(4): 531-540. (in English) [Italy "Sexual dimorphism is common in animals and derives from two mechanisms: sexual selection and sexual niche divergence. These mechanisms may work together as determinants of wing shape in pigmented wings of Odonata. On the one hand, sexual selection by females tends to enlarge the wing areas of males that host pigments; on the other hand, sex-specific flight behaviours, due to differential niche selection, may promote sexual dimorphism. Both sexes of *S. pedemontanum* have ornamented wings with bands, but their function is poorly understood. Therefore, we studied shape and size of wings and wing bands of *S. pedemontanum* using geometric morphometrics to quantify the extent of sexual dimorphism. We also investigated whether sexual dimorphism in wing shape derives from the effect of sexual selection on wing ornamentation or from sexual niche separation. We found sexual dimorphism in wing shape and in the shapes of the bands, but the absence and misdirection of sexual size dimorphism and wing shape dimorphism of bands do not support the hypothesis that wings and wing bands in *S. pedemontanum* are subjected to sexual selection. Instead, the pattern of sexual dimorphism in wing shape seems more likely to be caused by sex-specific flight requirements." 15279. Gazzola, A.; Brandalise, F.; Rubolini, D.; Rossi, P.; Galeotti, P. (2015): Fear is the mother of invention: anuran embryos exposed to predator cues alter life-history traits, post-hatching behaviour, and neuronal activity patterns. *Journal of Experimental Biology* 218: 3919-3930. (in English) ["Neurophysiological modifications associated to phenotypic plasticity in response to predators are largely unexplored, and there is a gap of knowledge on how the information encoded in predator cues is processed by prey sensory systems. To explore these issues, we exposed *Rana dalmatina* embryos to dragonfly chemical cues (kairomones) up to hatching. At different times after hatching (up to 40 days), we recorded morphology and antipredator behaviour of control and embryonic-treated tadpoles as well as their neural olfactory responses, by recording the activity

of their mitral neurons before and after exposure to a kairomone solution. Embryonic-treated embryos hatched later and originated smaller hatchlings than control siblings. In addition, embryonic-treated tadpoles showed a stronger antipredator response than controls at 10 (but not at 30) days post-hatching, though the intensity of the contextual response to the kairomone stimulus did not differ between the two groups. Baseline neuronal activity at 30 days post-hatching, as assessed by the frequency of spontaneous excitatory postsynaptic events and by the firing rate of mitral cells, was higher among embryonic-treated tadpoles compared to controls. At the same time, neuronal activity showed a stronger increase among embryonic-treated tadpoles than among controls after a local kairomone perfusion. Hence, a different contextual plasticity between treatments at the neuronal level was not mirrored by the antipredator behavioural response. In conclusion, our experiments demonstrate ontogenetic plasticity in tadpole neuronal activity after embryonic exposure to predator cues, corroborating the evidence that early-life experience can contribute to shaping the phenotype at later life stages." 15280. Geisinger, C.; Koch, K. (2015): Vergleich der Libellenfauna (Odonata) im Naturschutzgebiet Laubenheimer-Bodenheimer Ried in Mainz von 2006 bis 2014. *Mainzer naturwissenschaftliches Archiv* 52: 167-177. (in German, with English summary) [Rheinland-Pfalz, Germany "The odonate fauna in Mainz has been well studied in recent years. Particularly the nature reserve Laubenheimer-Bodenheimer Ried has turned out to have the highest species number. In 2007 and 2010 two new waters were created in the nature reserve area. The dragonfly fauna of these two waters has been mapped extensively in 2011 and 2014. In this study the current species composition of the area was compared with older data of the area (2006-2007, 2008-2013). The new natural protective waters appear to be the preferred emergence habitats for Odonata. In 2014 98.3% of all damselfly exuviae and 92.6% of all dragonfly exuviae were found at the new waters. At the older and well structured clay mining waters relatively few exuviae were found." (Authors)] Address: Geisinger, Christina, Berliner Str. 27, 55131 Mainz, Germany. E-Mail: ChrGeisinger@aol.com

15281. Gober, C. (2015): Dragonfly succession in ponds following disturbance by drying and refilling. Departmental Honors in the Department of Environmental Sciences, Texas Christian University, Fort Worth, Texas: (in English) ["Disturbance is an environmental factor that determines ecological community structure. For insect communities in small ponds, the primary disturbance factor is pond drying. Larval insects cannot survive pond drying, but they recolonize ponds after ponds refill. Little is known about dragonfly recolonization rates once ponds refill after a drying event. The purpose of this study was to determine recolonization rates for two dragonfly families after pond refilling. Over the summer of 2014, 10 experimental ponds were studied at

the Eagle Mountain Hatchery in Fort Worth, Texas. Five of the 10 experimental ponds were drained and dried for one month to simulate a natural drying disturbance. The other five ponds were not dried and contained fish. Dip net samples were collected every one to two weeks over a 10-week period. The dragonflies from each sample were identified and counted in order to track temporal changes within the dragonfly community. This study suggests that there are significant differences in recolonization rates for different families of dragonflies." (Author)] Address: not stated

15282. Grether, G.F.; Drury, J.P.; Berlin, E.; Anderson, C.N. (2015): The role of wing coloration in sex recognition and competitor recognition in rubyspot damselflies (*Hetaerina* spp.). *Ethology* 121(7): 674-685. (in English) ["The decision rules that animals use for distinguishing between conspecifics of different age and sex classes are relevant for understanding how closely related species interact in sympatry. In rubyspot damselflies (*Hetaerina* spp.), the red wing coloration of mature males is hypothesized to be a key trait for sex recognition and competitor recognition within species and the proximate trigger for interspecific male-male aggression. We tested this hypothesis by manipulating the wing coloration of tethered conspecific intruders and measuring the responses of territory holders of three species in the field. As predicted, covering the red spots of mature males with black ink nearly eliminated territorial responses, and in some cases, territorial holders clasped the blackened males as if they were females. Adding red spots to female wings triggered territorial responses and nearly eliminated sexual responses. Immature males with artificial red spots were attacked at the same rate as mature male intruders, and much more frequently than were immature male controls. The results varied somewhat by species. In *H. titia*, the only species of *Hetaerina* with substantial black wing pigmentation, the effects of blackening the red spots of intruders varied both geographically and seasonally. But even when blackening the red spots of male intruders did not reduce the aggressive response of *H. titia* territory holders, adding artificial red spots to female wings elicited aggressive responses and nearly eliminated sexual responses. The results of this study further strengthen the evidence that interspecific aggression in *Hetaerina* results from overlap in territorial signals and that the derived black wing pigmentation of *H. titia* reduces interspecific aggression." 15283. Grutters, B.M.C.; Pollux, B.J.A.; Verberk, W.C.E.P.; Bakker, E.S. (2015): Native and non-native plants provide similar refuge to invertebrate prey, but less than artificial plants. *PLoS ONE* 10(4): e0124455. doi:10.1371/journal.pone.0124455: 18 pp. (in English) ["Non-native species introductions are widespread and can affect ecosystem functioning by altering the structure of food webs. Invading plants often modify habitat structure, which may affect the suitability of vegetation as refuge and could thus impact

predator-prey dynamics. Yet little is known about how the replacement of native by non-native vegetation affects predator-prey dynamics. We hypothesize that plant refuge provisioning depends on (1) the plant's native status, (2) plant structural complexity and morphology, (3) predator identity, and (4) prey identity, as well as that (5) structurally similar living and artificial plants provide similar refuge. We used aquatic communities as a model system and compared the refuge provided by plants to macroinvertebrates (*Daphnia pulex*, *Gammarus pulex* and damselfly larvae) in three short-term laboratory predation experiments. Plant refuge provisioning differed between plant species, but was generally similar for native (*Myriophyllum spicatum*, *Ceratophyllum demersum*, *Potamogeton perfoliatus*) and non-native plants (*Vallisneria spiralis*, *Myriophyllum heterophyllum*, *Cabomba caroliniana*). However, plant refuge provisioning to macroinvertebrate prey depended primarily on predator (mirror carp: *Cyprinus carpio carpio* and dragonfly larvae: *Anax imperator*) and prey identity, while the effects of plant structural complexity were only minor. Contrary to living plants, artificial plant analogues did improve prey survival, particularly with increasing structural complexity and shoot density. As such, plant rigidity, which was high for artificial plants and one of the living plant species evaluated in this study (*Ceratophyllum demersum*), may interact with structural complexity to play a key role in refuge provisioning to specific prey (*Gammarus pulex*). Our results demonstrate that replacement of native by structurally similar non-native vegetation is unlikely to greatly affect predator-prey dynamics. We propose that modification of predator-prey interactions through plant invasions only occurs when invading plants radically differ in growth form, density and rigidity compared to native plants." 15284. Guillermo-Ferreira, R.; Bispo, P.C.; Appel, E.; Kovalev, A.; Gorb, S.N. (2015): Mechanism of the wing colouration in the dragonfly *Zenithoptera lanei* (Odonata: Libellulidae) and its role in intraspecific communication. *Journal of Insect Physiology* 81: 129-136. (in English) ["Highlights: • We studied the morphological mechanisms of colouration in a libellulid dragonfly. • Wax crystals form a composite structure that enhances colour. • Multi-layered structure of the pigmented cuticle results in iridescence. • Resulting colour is a cue for rival recognition in territorial fights. • Wax and pigment may impose physiological costs and be condition dependent. Abstract: Zenithoptera dragonflies are known for their remarkable bluish colouration on their wings and unique male behaviour of folding and unfolding their wings while perching. However, nothing is known about the optical properties of such colouration and its structural and functional background. In this paper, we aimed to study the relationship between the wing membrane ultrastructure, surface microstructure and colour spectra of male wings in *Zenithoptera lanei* and test the hypothesis that colouration functions as a signal in territorial fights between males. The results show that the specific wing colouration derives from

interference in alternating layers of melanized and un-melanized cuticle in the wing membrane, combined with diffuse scattering in two different layers of wax crystals on the dorsal wing surface, one lower layer of long filaments, and one upper layer of leaf-shaped crystals. The results also show that the thicker wax coverage of the dorsal surface of the wings results in increased brightness and reduced chroma. In the field experiments, we have demonstrated that there is a reduction of aggressive reactions of rivals towards individuals with experimentally reduced amount of blue wing colouration." 15286. Gvoždík, L.; Smolinský, R. (2015): Body size, swimming speed, or thermal sensitivity? Predator-imposed selection on amphibian larvae. *BMC Evolutionary Biology* 2015, 15:238 doi:10.1186/s12862-015-0522-y: 9 pp. (in English) ["Background: Many animals rely on their escape performance during predator encounters. Because of its dependence on body size and temperature, escape velocity is fully characterized by three measures, absolute value, size-corrected value, and its response to temperature (thermal sensitivity). The primary target of the selection imposed by predators is poorly understood. We examined predator (dragonfly larva [*Aeshna cyanea*])-imposed selection on prey (newt larvae) body size and characteristics of escape velocity using replicated and controlled predation experiments under seminatural conditions. Specifically, because these species experience a wide range of temperatures throughout their larval phases, we predict that larvae achieving high swimming velocities across temperatures will have a selective advantage over more thermally sensitive individuals. Results: Nonzero selection differentials indicated that predators selected for prey body size and both

absolute and size-corrected maximum swimming velocity. Comparison of selection differentials with control confirmed selection only on body size, i.e., dragonfly larvae preferably preyed on small newt larvae. Maximum swimming velocity and its thermal sensitivity showed low group repeatability, which contributed to non-detectable selection on both characteristics of escape performance. Conclusions: In the newt-dragonfly larvae interaction, body size plays a more important role than maximum values and thermal sensitivity of swimming velocity during predator escape. This corroborates the general importance of body size in predator-prey interactions. The absence of an appropriate control in predation experiments may lead to potentially misleading conclusions about the primary target of predator-imposed selection. Insights from predation experiments contribute to our understanding of the link between performance and fitness, and further improve mechanistic models of predator-prey interactions and food web dynamics." 15292. Harabis, F.; Dolny, A. (2015): Odonates need natural disturbances: how human-induced dynamics affect the diversity of dragonfly assemblages. *Freshwater Science* 34(3): 1050-1057. (in English) ["The still-growing effect of human activities on aquatic habitats has led to proportionately increasing need for restoration activities. Paradoxically, restoration actions can constitute a major threat to freshwater assemblages if they do not respect the specific nature of the target biotopes. We investigated the dynamics of dragonfly assemblages in 20 mine-subsidence pools (habitats with very high and very unpredictable dynamics). We used multivariate methods and diversity indices to compare species richness and species composition of assemblages before and after reclamation actions. During the 10 y of the study, we recorded 10 cases in which aquatic habitats disappeared completely and 6 cases of recovery and successful recolonization of aquatic pools. Disturbances caused by reclamation actions led to significant reduction of diversity and to extirpation of sensitive dragonfly species. Moreover, unlike natural disturbances, disturbances caused by reclamation activity do not support the occurrence of species associated with early successional stages. Major interventions in freshwater habitats can cause alterations that often paradoxically may result in local extinction of sensitive species rather than strengthening of existing populations." 15293. Harabis, F.; Dolny, A.; Helebrandova, J.; Ruskova, T. (2015): Do egg parasitoids increase the tendency of *Lestes sponsa* (Odonata: Lestidae) to oviposit underwater? *Eur. J. Entomol.* 112(1): 63-68. (in English) ["The selection of oviposition sites by insects can significantly affect egg mortality. Spreadwing damselflies (Odonata: Lestidae) predominantly lay their eggs in parts of plants growing above the surface of water and only occasionally also those parts growing underwater. Factors affecting the choice of oviposition site and decision to lay underwater are still poorly understood. We examined whether localities with different risk

of egg parasitism, different oviposition strategies (above or below the water surface) and the depth at which the eggs were laid, affected the total number of eggs laid, the proportion parasitized and egg mortality. In general, a significantly higher proportion of the eggs laid above the surface of water were parasitized but spreadwing damselflies showed significant preference for laying eggs underwater at both of the sites studied. This preference, however, had a different effect on the overall mortality of eggs at the two sites studied. Hence underwater oviposition by damselflies may be seen as a conditional anti-predator strategy, occurring only if the benefits exceed potential risks. Underwater oviposition may provide additional benefits other than protection against egg parasitism." 15295. Hassall, C. (2015): Strong longitudinal variation in wing aspect ratio of a damselfly, *Calopteryx maculata* (Odonata: Zygoptera). *PeerJ* 3:e1219; DOI 10.7717/peerj.1219: 17 pp. (in English) ["Geographical patterns in body size have been described across a wide range of species, leading to the development of a series of fundamental biological rules. However, shape variables are less well-described despite having substantial consequences for organismal performance. Wing aspect ratio (AR) has been proposed as a key shape parameter that determines function in flying animals, with high AR corresponding to longer, thinner wings that promote high manoeuvrability, low speed flight, and low AR corresponding to shorter, broader wings that promote high efficiency long distance flight. From this principle it might be predicted that populations at range edges would exhibit low AR wings. I test this hypothesis using the riverine damselfly, *Calopteryx maculata*, sampled from 34 sites across its range margin in North America. Nine hundred and seven male specimens were captured from across the 34 sites (mean=26.7±2.9 SE per site), dissected and measured to quantify the area and length of all four wings. Geometric morphometrics were employed to investigate geographical variation in wing shape. The majority of variation in wing shape involved changes in wing aspect ratio, confirmed independently by geometric morphometrics and wing measurements. There was a weak positive relationship between wing aspect ratio and temperature, in line with work on other insects. However, there was a strong longitudinal pattern in which western populations exhibited lower wing aspect ratio. This longitudinal pattern may be related

to increasing variability in precipitation from east to west in North America. I discuss my findings in light of research of the functional ecology of wing shape across vertebrate and invertebrate taxa." 15296. Hassall, C. (2015): Odonata as candidate macroecological barometers for global climate change. *Freshwater Science* 34(3): 1040-1049. (in English) ["Many investigators have described a footprint of global environmental change in macroecological trends across multiple taxa. However, little comparative analysis has been done to evaluate whether some taxa are responding more than others. I tested 2 hypotheses: 1) taxa vary strongly in terms of range shifts and phenological advances in their responses to changing climate, and 2) taxa that shift ranges also advance phenology. I used an initial database of >4 million recorded sightings of UK animal species from 24 orders and found descriptions of range shifts for 612 species and phenological trends for 923 species. I compared the 2 responses for 464 species and found wide variation in the extent to which taxa are responding. Vertebrate taxa were the least well recorded and showed weak or nonsignificant responses. Invertebrates were well recorded and responded strongly in range and phenology, but evidence of an association between range shifts and phenological advances was equivocal. My results show that different taxa are exhibiting different responses to the same environmental change, and that mechanistic and traits-based studies may reveal the causes of that variation. Spatial responses may be constrained by mode of dispersal, and insects and arachnids typically respond strongly, whereas terrestrial vertebrates do not. Phenological responses are complex and may involve species-specific physiological relationships between development and seasonal cues. Use of a model taxon could increase efficiency of monitoring regimes by simplifying monitoring targets and techniques. Potential exists for =1 taxa to be indicators of climate change, whereby the responses of one or a group of species could be used to infer changes at a broader taxonomic scale. I highlight Odonata as a taxon that responds strongly in multiple modalities, is charismatic enough to appeal to citizen scientists, and is an emerging physiological and genetic model." 15297. Hassall, C.; Sherratt, T.N.; Watts, P.C.; Thompson, D.J. (2015): Live fast, die old: no evidence of reproductive senescence or costs of mating in a damselfly (Odonata: Zygoptera). *Journal of Animal Ecology* 84(6): 1542-1554. (in English) ["(1.) Recent examples of actuarial senescence in wild insect populations have challenged the long-held assumption that the brevity of wild insect life spans precludes senescence. (2.) We investigate age-related patterns in mating behaviour in adults of a short-lived damselfly, *Coenagrion puella* and the implications of this mating. Using capture histories for 1033 individuals over two field seasons, we conduct both pooled and stratified analyses of variations in breeding activity. (3.) Pooled analyses suggest that there is strong age-related variation in the probability of

being present at the mating rendezvous. However, no age-related variation was observed in the probability of mating. Stratified approaches confirmed a general pattern of age-related declines in survival probability, but provided only equivocal evidence of an effect of age on transition between temporary breeding states. Mating males and females showed greater survival than non-mating individuals, possibly as a consequence of higher body condition. Older males that were not currently breeding were less likely to commence breeding on the next day, but showed no patterns in breeding cessation. Overall, transitions between both breeding states declined with age, suggesting that males that breed tend to continue breeding while those that do not breed continue to be unsuccessful. Female mating rates were consistently high across all ages with no age-related decline apparent. (4.) While previous research has demonstrated actuarial senescence in this population, as does this study, we find little evidence of either age-related declines in reproductive behaviour or breeding-related declines in survival, which might indicate functional senescence or costs of mating, respectively. Indeed, the greater survival in mating individuals of both sexes suggests that variations in individual quality may mediate both reproductive success and longevity. (5.) Contrary to recent studies, we found no compelling evidence for reproductive senescence or a cost of mating in an important and well-studied model odonate. The possible link between condition and ageing suggests that individual quality needs to be taken into account when studying senescence. We recommend the use of multistrata models for the future investigation of these phenomena." (Authors)] Address: Hassall, C., Dept Ecol., Univ. Oulu, PO Box 3000, Oulu 90014, Finland. 15298. Hassall, C.; Anderson, S. (2015): Stormwater ponds can contain comparable biodiversity to unmanaged wetlands in urban areas. *Hydrobiologia* 745: 137-149. (in English) ["Urban freshwaters provide a range of ecosystem services, including stormwater management, water treatment, biodiversity, and aesthetics. Management of freshwaters should aim to maximise as many of these services as possible, but managers are often focused on individual services. To test for the biodiversity value of stormwater management ponds (SMPs) in Ottawa, Canada, 20 SMPs were surveyed for macroinvertebrates using standardised sampling techniques. These were compared against 10 wetlands that were not managed for stormwater control (a combination of ornamental lakes, natural lakes, and nature reserves) in and around the same urban area (a total of 30 ponds). Natural wetlands and SMPs were very different in their water chemistry, which was correlated with the proportion of urban land use within 1 km of the site, with higher conductivity in SMPs with increasing urban land cover ($P = 0.046$). Despite this, natural wetlands and the richest SMPs contained similar levels of biodiversity and similar macroinvertebrate community structure. This study highlights that stormwater management can occur alongside biodiversity enhancement in urban areas, but correlations between urban land use, water chemistry, and the structure of biological communities suggests that run-off from urban areas is

likely a major factor in structuring biological communities in built-up regions." (Authors) Taxa including Odonata are treated at family level.] Address: Hassall, C., School of Biology, University of Leeds, Leeds, LS2 3JT, UK. E-mail: c.hassall@leeds.ac.uk

15299. Hedrick, T.; Combes, S.A.; Miller, L.A. (2015): Recent developments in the study of insect flight. *Canadian Journal of Zoology* 93(12): 925-943. (in English) ["Here we review recent contributions to the study of insect flight, in particular those brought about by advances in experimental techniques. We focus particularly on the following areas: wing flexibility and deformation, the physiology and biophysics of asynchronous insect flight muscle, the aerodynamics of flight, and stability and maneuverability. This recent research reveals the importance of wing flexibility to insect flight, provides a detailed model of how asynchronous flight muscle functions and how it may have evolved, synthesizes many recent studies of insect flight aerodynamics into a broad-reaching summary of unsteady flight aerodynamics insects, and highlights new insights into the sources of flight stability in insects. The focus on experimental techniques and recently developed apparatus shows how these advancements have occurred and point the way towards future experiments." (Authors) The publication includes references to dragonflies.] Address: Hedrick, T., Department of Biology, University of North Carolina at Chapel Hill, Chapel Hill, NC 27599, USA. 15300. Heintzman, L.J.; Anderson, T.A.; Carr, D.L.; McIntyre, N.E. (2015): Local and landscape influences on PAH contamination in urban stormwater. *Landscape and Urban Planning* 142: 29-37. (in English) ["Highlights: •We assessed polycyclic aromatic hydrocarbons in urban stormwater and odonates. •Contamination (amounts and agents) differed between water and odonate tissues. •Local factors were more important than landscape factors on PAH levels. •PAHs did not accumulate along a stormwater gradient. Abstract: Polycyclic aromatic hydrocarbons (PAHs) are toxic organic pollutants produced from combustion. Associated with urban runoff, they have been detected worldwide in urban wetlands. Because PAHs and their associated metabolites are often carcinogenic, mutagenic, and teratogenic, they can pose significant risks to wetland-dependent organisms. We investigated the occurrence of 16 PAHs within water samples and tissues of *Enallagma civile* from seven urban wetlands (known regionally as playas) along a constructed stormwater gradient in Lubbock, Texas. PAH detections from water samples were highly variable across sites and dates, with naphthalene and pyrene occurring most often. PAH detections in adult damselflies were also variable but significantly different from corresponding water samples (suggesting bioaccumulation rather than passive chemical exposure), with naphthalene and fluoranthene occurring most often. The number of specific PAH detections was significantly associated with percent impervious surface within 300 m of a playa, but not with position along the stormwater gradient or number of drainage inflows. Therefore, for the urban playas and odonates of Lubbock, local

factors were more important in determining PAH contamination than were landscape-level factors. PAH contamination can be reduced in future urban landscape planning and design by minimizing the amount of impervious surface around stormwater retention ponds, even if they are linked along a hydrologic gradient." 15301. Hernández Rodríguez (2015): Utility of morphometric standardized variables of wing for automated identification of Cuban species and genus of Libellulidae (Insecta: Odonata). *Revista Cubana de Ciencias Biológicas* 4(2): 78-89. (in Spanish, with English summary) ["The classification of the Cuban Odonata is difficult by the complexity of wing venation. These appendixes have become in very useful tools in studies of geometric morphometrics. For this reason the objective of this work is the evaluation of the potential of wing shape differences for numeric classification and as a basis for an automated identification system for genera and species of the family Libellulidae in Cuba. Landmarks were placed in the fore and hind wings. The landmarks configurations were standardized using Procrustes registration. For the taxonomy analysis three shape variables and six lineal, were used for discriminants analysis and classification and regression tree analysis (CART). The discriminant analyses get a 100% of correct discrimination for both wings in 12 species and 8 genera. The trees CART showed groups mixed in the terminal nodes for both wings, however, for the genera the classification tree showed high purity. The results obtained in this study may be used for creation of automatic classification program for the Libellulidae genera correctly classified with analyzed variables." 15302. Hernández Rodríguez, M.; Ávila, D.D. (2015): Diferencias interespecíficas y geográficas en los niveles de asimetría fluctuante en las alas de *Erythrodiplax umbrata*, *Macrothemis celeno* y *Pantala flavescens* (Odonata: Libellulidae). *Poeyana* 501: 8-19. (in Spanish, with English summary) ["Interspecific and geographic differences in fluctuating asymmetry level. Odonata show fluctuating asymmetry like the majority of insects. The distribution of the Cuban dragonflies varies among country regions. However, it remains unknown if this regional variation is reflected in the morphological characteristics of species with wide distribution, mainly over sensitive morphological indexes like the levels of corporal asymmetry. For this reason the objective of this work is the identification of interespecific differences in the levels of fluctuating asymmetry in wings of Cuban dragonflies and their comparison between two country regions. Digital pictures of *Macrothemis celeno*, *Erythrodiplax umbrata* and *Pantala flavescens* (120) were taken. The landmarks were placed in fore and hind wings of both sides of the body, using the program tpsDig. Procrustes superimposition methods, shape principal components analysis,

analysis of euclidean distances matrix and Thin Plate Spline were used for shape analysis. Centroid size, distances between centroids (the differences among species and regions they were proven by Montecarlo analysis), and lineal distances were employed to measure the degree of asymmetry. The Montecarlo test revealed significant differences between *E. umbrata* and *P. flavescens* for the hind wings and between the populations of *E. umbrata* and *M. celeno* of the western and eastern regions. The sum of lineal distances, used as a measure of asymmetry, showed differences in fore wings of *E. umbrata* among both regions of the country, but not among species. The differences found in the levels of asymmetry among species and regions they could be cause of uncertainty in the development, environmental stress and to be reflected directly in processes like the couple's selection, the agility of the flight and the maneuverability, for that to describe this characteristic in the Cuban dragonflies could supplement the studies of ecology, reproductive biology and behaviour carried out until the moment." (Authors)] Address: Hernández Rodríguez, Majela, Facultad de Biología, Universidad de La Habana, calle 25 e/ I y J, Vedado, Plaza de la Revolución, Cuba. E-mail: majela@fbio.uh.cu

15303. Hettyey, A.; Tóth, Z.; Thonhauser, K.E.; Frommen, J.G.; Penn, D.J.; Van Buskirk, J. (2015): The relative importance of prey-borne and predator-borne chemical cues for inducible antipredator responses in tadpoles. *Oecologia* 179(3): 699-710. (in English) ["Chemical cues that evoke anti-predator developmental changes have received considerable attention, but it is not known to what extent prey use information from the smell of predators and from cues released through digestion. We conducted an experiment to determine the importance of various types of cues for the adjustment of anti-predator defences. We exposed tadpoles (*Rana temporaria*) to water originating from predators (caged larvae, *Aeshna cyanea*) that were fed different types and quantities of prey outside of tadpole-rearing containers. Variation among treatments in the magnitude of morphological and behavioural responses was highly consistent. Our results demonstrate that tadpoles can assess the threat posed by predators through digestion-released, prey-borne cues and continually released predator-borne cues. These cues may play an important role in the fine-tuning of anti-predator responses and significantly affect the outcome of interactions between predators and prey in aquatic ecosystems. There has been much confusion regards terminology used in the literature, and therefore we also propose a more precise and consistent binomial nomenclature based on the timing of chemical cue release (stress-, attack-, capture-, digestion- or continually released cues) and the origin of cues (prey-borne or predator-borne cues). We hope that this new nomenclature will improve comparisons among studies on this topic." 15304. Hill, M.J.; Mathers, K.L.; Wood, P.J. (2015): The aquatic macroinvertebrate biodiversity of urban ponds in a

medium-sized European town (Loughborough, UK). *Hydrobiologia* 760: 225-238. (in English) ["Urbanisation is one of the greatest threats to freshwater biodiversity, with the area of land covered by towns and cities predicted to increase significantly in the future. Ponds are common features in the urban landscape and have been created for a variety of reasons ranging from ornamental/amenity purposes through to the detention of urban runoff and pollution. This paper aims to quantify the aquatic macroinvertebrate biodiversity associated with garden, ornamental and other urban ponds in Leicestershire, UK. We examined the macroinvertebrate biodiversity of 41 urban ponds (13 garden, 12 park and 16 other urban ponds) within the town of Loughborough, UK. Park ponds supported greater macroinvertebrate richness than garden or other urban ponds. Garden ponds were the most taxon poor. Pond size was strongly correlated with macroinvertebrate diversity. Collectively, urban ponds were found to be physically and biologically heterogeneous and were characterised by high community dissimilarity. Urban ponds provide a diverse range of habitats for a mixture of common and rare aquatic macroinvertebrate taxa and represent a valuable biodiversity resource within anthropogenically dominated landscapes. Recognition of the significant contribution of ponds to urban freshwater biodiversity is important for future aquatic conservation within anthropogenically dominated landscapes." (Authors) *Anax imperator*, *Aeshna mixta*, *Coenagrion puella*.] Address: Hill, M.J., Dept of Geography, Centre for Hydrological and Ecosystem Science, Loughborough University, Loughborough, Leicestershire LE11 3TU, UK. 15305. Hiroshi, J.; Uéda, T. (2015): Can the use of more selective insecticides promote the conservation of *Symptetrum frequens* in Japanese rice paddy fields (Odonata: Libellulidae)? *Odonatologica* 44(1/2): 63-80. (in English) ["The effect of two relatively selective nursery-box-applied insecticides on *S. frequens* larvae and adults as substitutes for the commonly used insecticides, imidacloprid and fipronil, was examined using an experimental micro-paddy lysimeter (MPL) system. Fifty hatched larvae were placed on the soil surface of separate MPLs that had been treated with imidacloprid, fipronil, dinotefuran, and cartap hydrochloride, as well as an untreated control MPL. At 30 days after transplantation, the complete absence of *S. frequens* larvae and exuviae in the imidacloprid and fipronil-treated MPLs was remarkable. In the control, cartap- and dinotefuran-treated MPLs, the mean number of larvae was 31.0 ± 6.0 , 27.0 ± 6.0 , and 6.3 ± 1.5 , respectively. No *S. frequens* adults were observed later in the imidacloprid- and fipronil-treated MPLs. The rate of emergence did not differ significantly among the control, cartap- and dinotefuran-treated MPLs. However, the mean head width of *S. frequens* in the dinotefuran-treated MPL was significantly narrower than that of *S. frequens* in the control and cartap-treated MPLs. The mean EM50 in the cartap-treated MPL was significantly longer than that in the control- and dinotefuran-treated MPLs. The findings showed that the ecological impact of cartap on *S. frequens* was slightly less than the application of fipronil, imidacloprid and dinotefuran to rice paddy fields." (Authors)]

15313. Hyytiäinen, A. (2015): Kymmenen vuotta sudenko-
rentojen lajihavainnointia Lohjan Santojalla (2005–2014) [Ten years of dragonfly observation at Lohja]. *Crenata* 8: 4-9. (in Finnish) [Detailed information on a ten-year survey of the Odonata fauna of a small area at the city of Lohja (SW Finland) is provided. The four observation sites within the study area were composed of a section of the waterside of

Lohjanjärvi lake, an artificial pond at a former sand pit, a mire and a logging site. During the period 2005-2014 a total of 32 species were recorded, corresponding to more than half of the Finnish odonate species. Of particular note were *Sympecma paedisca*, *Coenagrion armatum*, *C. johanssoni*, *Epithea bimaculata*, *Cordulegaster boltonii*, *Leucorrhinia albifrons* and *L. pectoralis*. [A. Schröter]]

15314. Ichikawa, Y.; Watanabe, M. (2015): The daily food intake of *Pantala flavescens* females from foraging swarms estimated by the faeces excreted (Odonata: Libellulidae). *Odonatologica* 44(3): 375-389. (in English) ["*P. flavescens* migrates to Japan every spring, where the population rapidly increases until autumn. Adults often form swarms above open grasslands for foraging. Little has been reported on the daily food intake in *P. flavescens*, probably due to the difficulty of observing foraging behaviour. We captured females from foraging swarms and kept them alive in the laboratory, and the faeces excreted were collected each 24-hour-period after capture. Faeces excreted within 24 hours after capture were typically dark brown, formed in oval pellets, including a lot of fragments of cuticle, which must have been derived from the prey. The total dry weight of faeces was 8.00 mg on average. The size of the subsequent faeces decreased, and the colour changed to reddish brown and detectable cuticle fragments were no longer present, suggesting that most of the indigestible parts had been excreted within 24 hours after feeding. When a female was handfed a single sheep blowfly, 4.51 mg of faeces were excreted within 24 hours after feeding, while a starved female excreted 2.23 mg. The daily food intake of a female was estimated to be about 14 mg, corresponding to about 185 small prey insects. Therefore, the mass flight of *P. flavescens* might affect populations of small insects in the open landscape in Japan." 15315. Ihechiluru, N.B.; Henry, A.N.; Taiwo, I.E. (2015): Heavy metal bioaccumulation and oxidative stress in *Austroaeschna inermis* (Dragon fly) of the Lagos Urban ecosystem. *J. Environ. Chem. Ecotoxicol.* 7(1): 11-19. (in English) ["Urban ecosystems are often characterized by the receipt of pollutants, especially heavy metals from diverse anthropogenic activities. To better understand the distribution of heavy metals (Cd, Cu, Pb, Mn and Zn), *A. inermis* from five different sites (Unilag, Mile 12, Olushosun Dump site, Imoshe and Badagry) in Lagos, sediments from the respective sites were assessed. This was followed by assessment of lipid peroxidation product; Malondialdehyde (MDA) and antioxidative stress enzymes; superoxide dismutase (SOD), catalase (CAT), glutathione S-transferase (GST) and reduced glutathione (GSH) in *A. inermis*. The results indicate widespread heavy metal distribution with Mn and Zn having the highest concentrations of 13.369 ± 0.800 mg/kg and 21.473 ± 2.001 mg/kg in sediment samples from Mile 12 and Olushosun Dump site respectively. Only Cd was bioaccumulated at two sites (Unilag and Badagry) with biota to soil

accumulation factor (BSAF) of approximately 2. The oxidative stress biomarkers assessment in the insects did not indicate any trend to link heavy metal concentrations with respective sites. However there was strong ($r = 0.5 < 0.7$) to very strong ($r = 0.7$) positive correlation between Pb concentrations in *A. inermis* and most biomarkers. All enzymes and MDA showed negative correlation with the other heavy metals with values mostly between strong ($r = -0.5 < -0.7$) to very strong ($r = -0.7$) negative. The findings from this study reaffirms the ubiquity of heavy metals in the City of Lagos and the relevance of the insects as pollution indicators were discussed." (Authors) Of course, *Austroaeschna inermis* is no resident in Nigeria, Africa.] Address: Henry, A.N., Dept of Zoology, University of Lagos, Akoka-Yaba, Lagos State, Nigeria. Email: amaezenh@gmail.com

15316. Ikemeyer, D.; Schneider, E.; Schneider, J.; Schneider, T. (2015): Records of Odonata in North- and North-East Iran including *Sympecma gobica* (Forster, 1900) as a new species for Iran. *Entomologische Zeitschrift* 125(3): 147-152. (in English, with German summary) ["During two field trips (15.–22. July 2013 and 12.–25. July 2014) to the North and North-East provinces of Iran: Gilān, Māzandarān, Golestān, North Chorāsān und Razavi Chorāsān a total of 37 Odonata species could be recorded. *Sympecma gobica* is new for Iran, and now extends its known range significantly to the West. The two most spectacular dragonfly species of the Hyrcanian Forest have recently been described *Aeshna vercanica* and *Cordulegaster vanbrinkae*, which could both be observed again and new insights into their behaviour could be added. *Sympetrum arenicolor* was found in North-Chorāsān, so far only known from a specimen not precisely located and dated in Iran. *Calopteryx orientalis* was frequently observed on shaded running waters in the entire visited region. All females in the provinces Gilān, Māzandarān and Golestān were androchromic. However, in North Chorāsān also heterochrome females were found among the majority of androchromic females. Further east all females were heterochrome and no homochrome (androchromic) females could be detected." (Authors)] Address: Ikemeyer, D., Billerbecker Str. 6, 48329 Havixbeck, Germany. E-Mail: DKJlkemeyer@t-online.de

15317. Ilvonen, J.J.; Kaunisto, K.M.; Suhonen, J. (2015): Are genders equally parasitized in damselflies and dragonflies? *Oikos* 125(3): 315-325. (in English) ["Parasitism plays an essential part in ecology and evolution of host species and understanding the reasons for differential parasitism within and among hosts species is therefore important. Among the very important factors potentially affecting parasitism is the gender of the host. Here, we studied whether either females or males are more likely to harbour parasites among Odonatan insects, by relying on an extensive literature review and new field data. We collected data on numerous dragonfly and damselfly species and their ectoparasites (water mites) and endoparasites (gregarines) to examine the generality of similarities and differences in prevalence, intensity and maximum number of parasites of male and female hosts. We found three main results. Firstly, most of the

odonate host species showed no differences between genders in either gregarine or water mite prevalence and intensity. The only exception was female damselflies' higher gregarine prevalence and intensity compared to conspecific males. These inequalities in gregarine parasitism may be due to behavioural and physiological differences between conspecific males and females. In comparison, there were no differences in dragonflies between genders in water mite or gregarine prevalence and intensity. Secondly, damselflies had higher prevalence and intensity levels of both gregarine and water mite parasites compared to dragonflies. Finally, we found a strong species level pattern between female and male parasitism: a certain level of gregarine or water mite parasitism in one sex was matched with a similar parasitism level for the other. This indicates similar exposure and susceptibility to parasites on both genders. Even though significant differences of parasite levels between the genders were observed within certain host species, our results strongly suggest that on a general level a more parasitized sex does not exist in the order, Odonata." 15318. Iversen, L.L.; Rannap, R.; Briggs, L.; Sand-Jensen, K. (2015): Variable history of land use reduces the relationship to specific habitat requirements of a threatened aquatic insect. *Population Ecology* 58(1): 155-164. (in English) ["The hutchinsonian realized niche of a species is the most common tool for selecting the actions needed when restoring habitats and establishing conservation areas of species. However, defining the realized niche of a species is problematic due to variation across spatial and temporal scales. In this study we tested the hypothesis that habitat parameters defining the realized niche of a species can be derived from a regional study and that national changes in land use influence the perception of the realized niche across different landscapes. We described the realized habitat niche of the threatened dragonfly *Leucorrhinia pectoralis*, in four Estonian landscapes which all have undergone more than 20 years of habitat degradations. We recorded the presence/absence of *L. pectoralis* and measured 7 habitat variables for 140 lakes and ponds located in one restored and three un-restored landscapes. Lake size and proportion of short riparian vegetation were significantly positive parameters determining the presence of *L. pectoralis* across landscape types. The species was much more habitat specific in the restored landscape, with larger influence of other habitat parameters. Our data suggest that the realized niche of the species in the un-restored landscapes was constrained by the present-day habitats. The study demonstrate that if a

species realized niche is derived from local distribution patterns without incorporating landscape history it can lead to an erroneous niche definition. We show that landscape restoration can provide knowledge on a species' habitat dependencies before habitat degradation has occurred, provided that restoration mitigation reflects the former landscape characteristics." 15319. Jaggwe, A. (2015): Effects of environmental variables on four aquatic insect taxa among smaller water bodies of different ages on farmland. A pilot study. M.Sc. thesis, Halmstad University, School of Business, Engineering and Science, Biological and Environmental Systems (BLESS): 22 pp. (in English) ["High anthropogenic modification like infrastructural development, drainage, eutrophication, dumping garbage, is a threat to biodiversity of smaller water bodies in agricultural landscapes. However, smaller water bodies have historically been constructed for drainage, waste treatment and other purposes. Further, new small water bodies are now being constructed in agricultural areas in Sweden, mainly to remove nutrients and to improve landscape biodiversity. This creates two different age classes (old and new) of smaller water body habitats. I sampled aquatic insects in 27 smaller water bodies of varying types and ages in Halmstad region and related insect biodiversity, species richness, composition structure to environmental variables. I partitioned the region into two locations (Northern and Southern) for easy data comparison and due to difference in topography. The data was analysed using a Canonical Correspondence (CCA) and regression analysis. The CCA results show a difference in the species composition between old and new sites. The most important variables in explaining species assemblage structure was age of the aquatic water bodies. The species richness decreased with increase in nutrient concentration (total phosphorus) according to regression analysis. Species composition and diversity were related to Vegetation and tree cover in and around the water body. The results of my study shows that the older the water bodies the better for specific species like *Aeshna cyanea* and the new water bodies tolerate more specimens. My results suggest that, as there is need to facilitate plant growing, protecting vegetation and trees to better mimic natural conditions of water bodies, creating new water bodies while protecting aged water bodies is important for conservation of biodiversity." 15320. Jamwal, D.; Verma, P.; Thaokar, N.; Andrew, R.J. (2015): Seasonal variation in the odonates dragonflies of Gandhi Sagar lake of Nagpur city, India. *International Journal of Pharmacology & Biological Sciences* 9(1): 49-53. (in English) ["Gandhi Sagar Lake is one of the most polluted water body of Nagpur city and is located in the centre of thickly populated residential area. Odonates are directly affected by water pollution since the major period of their life cycle as nymphs is spent in water. Although odonates are

categorized as "moderately intolerant organisms" in a water body, no attempts have been undertaken to study the species specific intolerance level in Odonata. The following presentation describes the observation of the seasonal variation of odonates breeding in the polluted water of Gandhi sagar lake. The following eleven odonates were observed breeding in the Gandhi sagar lake: *Anax guttatus*, *Ictinogomphus rapax*, *Brachythemis contaminata*, *Bradinopyga geminata*, *Crocothemis servilia servilia*, *Diplacodes trivialis*, *Orthetrum s. sabina*, *Pantala flavescens*, *Ceriagrion coromandelianum*, *Ischnura aurora* and *I. senegalensis*. These odonates species appear to be robust and opportunistic species and can be categorised as "fairly tolerant organisms". 15321. Janekova, K.; David, S.; Petrovičová, K. (2015): Contribution to the knowledge of dragonflies (Odonata) of the Orava river basin. *Folia faunistica Slovaca* 20(2): 145-155. (in Slovak, with English summary) ["The Orava River basin covers a total area of 1 633 km², there are a lot of marsh habitats, mainly two major types of peatlands – bogs and fens. The authors put together a faunistic overview of the dragonfly data, which were obtained between 2010 and 2014. A total of 36 dragonfly species were identified from 16 investigated localities, detailed records are given. There are 30 species recorded as autochthonous. There are many endangered and protected species, for instance *Sympetma fusca*, *Coenagrion hastulatum*, *Somatochlora arctica*, *Leucorrhinia caudalis*, *L. dubia*, *L. pectoralis*, *L. rubicunda*, there are species of European importance as well. The area is characterized by a sphagnophilous dragonfly fauna, also the complex of small water bodies, the sand and gravel pits, ditches and marshes drainage channels are of a great importance too." 15322. Jansen, E.; Sardar, F. (2015): Determination of the Southern Darter (*Sympetrum meridionale*) Selys, 1841. *Brachytron* 17(2): 65-75. (in Dutch, with English summary) ["The increased occurrence of *Sympetrum meridionale* in Belgium and the Netherlands renders the identification of *Sympetrum* species more difficult than before. We summarized and verified all known identification characteristics distinguishing *S. meridionale* from its look-alikes *S. vulgatum* and *S. striolatum* on museum specimens and photographs. Moreover, we identified and tested a novel characteristic which allows the separation between these species: *S. meridionale* has pale-colored veins at its wing-base which are absent in *S. vulgatum* and *S. striolatum*. Separating *S. meridionale* from *S. vulgatum* and *S. striolatum* remains tricky despite this new characteristic as exceptions to the rules do occur. Therefore we emphasize that for a reliable identification looking at a combination of characteristics remains necessary." (Authors)] Address: Esther Jansen & Fazal Sardar. E-mail: info@macromia.nl

15323. Janssens, L.; Van Dievel, M.; Stoks, R. (2015): Warming reinforces nonconsumptive predator effects on prey growth, physiology, and body stoichiometry. *Ecology* 96(12): 3270-3280. (in English) ["While nonconsumptive effects of predators may strongly affect prey populations, little is known how future warming will modulate these effects. Such information would be especially relevant with regard to prey physiology and resulting changes in prey stoichiometry. We investigated in *Enallagma cyathigerum* damselfly larvae the effects of a 4°C warming (20°C vs. 24°C) and predation risk on growth rate, physiology and body stoichiometry, for the first time including all key mechanisms suggested by the general stress paradigm (GSP) on how stressors shape changes in body stoichiometry. Growth rate and energy storage were higher at 24°C. Based on thermodynamic principles and the growth rate hypothesis, we could demonstrate predictable reductions in body C:P under warming and link these to the increase in P-rich RNA; the associated warming-induced decrease in C:N may be explained by the increased synthesis of N-rich proteins. Yet, under predation risk, growth rate instead decreased with warming and the warming-induced decreases in C:N and C:P disappeared. As predicted by the GSP, larvae increased body C:N and C:P at 24°C under predation risk. Notably, we did not detect the assumed GSP-mechanisms driving these changes: despite an increased metabolic rate there was neither an increase of C-rich biomolecules (instead fat and sugar contents decreased under predation risk), nor a decrease of N-rich proteins. We hypothesize that the higher C:N and N:P under predation risk are caused by a higher investment in morphological defense. This may also explain the stronger predator-induced increase in C:N under warming. The expected higher C:P under predation risk was only present under warming and matched the observed growth reduction and associated reduction in P-rich RNA. Our integrated mechanistic approach unraveled novel pathways of how warming and predation risk shape body stoichiometry. Key findings that (1) warming effects on elemental stoichiometry were predictable and only present in the absence of predation risk and that (2) warming reinforced the predator-induced effects on C:N:P, are pivotal in understanding how nonconsumptive predator effects under global warming will shape prey populations." 15325. Jisha Krishnan, E.K.; Sebastian, C.D. (2015): Analysis of evolutionary divergence of *Neurothemis tullia* (Odonata: Libellulidae) using cytochrome oxidase subunit I gene.

International Journal of Advanced Life Sciences 8(2): 110-114. (in English) [*N. tullia* is an andromorphic libellulidae member commonly found in ponds, marshes, paddy fields, swamps and tanks. Since this species exhibits female polymorphism and sexual dimorphism, the present study analyzed the nucleotide sequence of mitochondrial cytochrome oxidase I (COI) gene to predict any genetic changes that had occurred in this highly conserved region. Results showed that male, female and andromorphic female members showed the same 351 bp length COI gene (GenBank Accession: KP 835513). Phylogenetic tree constructed by the neighbour joining method showed that it is having a sister clade relationship of the same species found in Mizoram with a maximum bootstrap value of 100. Even though sexual dimorphism in the body colouration, body patterns, wing spot, etc may cause misidentification, the present DNA sequence analysis leads to the absolute identification of this species. The male, female and andromorphic female have same base pair length DNA, which confirmed them to belong to the same species. Phylogenetic tree depicted that different species of *Neurothemis* have a sequence divergence in the range of 1-12% and all showed a monophyletic ancestry representing splitting from a single clade and thereby confirmed genus level taxonomy. The study concludes that a vicariance may be the probable reason for the splitting up of this genus into different geographical areas and caused the reproductive isolation of the same genus which in turn leads to the formation of different species." (Authors)] Address: Sebastian, C.D., Molecular Biology Lab., Dept of Zoology, Univ. of Calicut, Kerala 673 635 India. E-mail: drcdsebastian@gmail.com

15326. Johnston, P.R.; Mikolajewski, D.J.; Rolff, J. (2015): Identification of viruses associated with larvae of *Leucorhinia dubia*, and *Coenagrion puella* from RNA sequencing data. *International Journal of Odonatology* 18(1): 81-88. (in English) ["Odonata are hosts to a variety of parasites and pathogens. However, very few studies have investigated which viruses infect dragonflies and damselflies. Here, based on next generation RNA sequencing of RNA from *Leucorhinia dubia* and *Coenagrion puella* larvae, data on putative viruses present in odonates are reported. In both species around 20 different putative viruses, often belonging to genera known from other insect species, were found. The annotated genome structure of one novel putative iflavirus in *C. puella* and new putative iflavirus, dicistrovirus and posa-lika viruses in *L. dubia* are described. The influence of these viruses on host fitness and their modes of transmission remain to be determined." (Authors)] Address: Mikolajewski, D.J., Freie Univ. Berlin, Inst. 15327. Jones, B.R.; Jordan, S. (2015): Genetic consequences of Pleistocene sea-level change on Hawaiian Megalagrion damselflies. *Journal of Heredity* 106(5): 618-627. (in English) ["The Hawaiian Islands have long been an important laboratory for evolutionary research because their geological histories offer many natural experiments. For ex-

ample, the Maui Nui complex, 4 islands that have been repeatedly connected and separated by fluctuating sea levels, lie near Hawaii Island, which has never been connected to another island. Here, we examine the genetic consequences of fluctuating island areas and connectivity using microsatellite analysis of 2 widespread, endemic Hawaiian damselflies. We screened 152 *Megalagrion xanthomelas* individuals from 5 islands at 14 loci and 34 *Megalagrion pacificum* from 3 islands at 11 loci to explore dispersal patterns and genetic diversity. Our data suggest that Pleistocene fluctuations in sea level alternated between creating land bridges that facilitated gene flow between once and future islands, and ocean channels that inhibited dispersal. Furthermore, interglacial periods of high sea stands likely reduced suitable habitat availability, causing the loss of genetic diversity on Maui Nui due to bottlenecks and founder events. Finally, we propose that gene flow from Molokai to Lanai may be enhanced by assisted dispersal from the trade winds that are channeled between volcanoes on western Maui and eastern Molokai. Our results emphasize the importance of variable microevolutionary processes in Hawaiian biogeography." 15330. Karadimas, D. (2015): The Nina-Nina, the Devil and Oruro: The origins of a diabolical figure. *Indiana* 32: 23-45. (in English, with Spanish summary) ["The Diablada festivities, which take place in Oruro mining town in Bolivia, stage 'devils' that come out of the underworld through galleries and mines that communicate with the surface. The captions that accompany the worship of the Virgin of the Mine (Virgen de la Mina) on this occasion show a hero whose nickname in Quechua likewise designates a parasitic wasp, nina nina. In the world of the Andes, this wasp was associated with bad omens and to the devil by the Indian scholar Guaman Poma de Ayala in the 17th century. The contribution refers to these identifications to propose a new approach to the origin of the Diablada festivities suggesting that in the iconographic features of the devil could be recognized the features of the gods of the mountains worshiped by present and pre-Hispanic Andean populations. ... Dragonflies can thus also be designated with the term aya wantu and are also drawn on some pre-Hispanic pottery next to pompilid wasps, such as this Inca-style aribalo preserved in the Rafael Larco Museum where the dragonflies, recognizable thanks to their outstretched wings, are placed next to insects which until now had been interpreted as butterflies, although the drawing and the colours of their wings (orange, or smoky surrounded by black) are typical of pompilid wasps" (Author) The paper includes a further figure "Inca aribalo on which there are flies, dragonflies and pompilid wasps (Ethnologisches Museum, Berlin, V A 49836." with dragonflies pictured.] Address: Karadimas, D., CNRS – Laboratoire d'Anthropologie sociale, France

15331. Karlsson, T. (2015): Östergötlands Trollsländor. Entomologiska Föreningen Östergötland: 160 pp. (in Swedish, with English summary) ["Östergötlands Trollsländor is a compilation of the results of a survey of dragonflies in the Swedish county Östergötland during 2008-2012, together with older records. The survey was performed by the Entomological Society in Östergötland, and this society is also the publisher of the book. Östergötlands Trollsländor is the first regional atlas of dragonflies in Sweden. It presents all 52 species noted for Östergötland with pictures and a distribution map. For threatened and rare species pictures of the

habitat is also presented. In addition, the book makes comprehensive comparisons between Östergötland and ten other regions in Europe (Sweden, Latvia, Polen, Germany, Great Britain and France) to show what distinguishes the dragonfly fauna in Östergötland." 15334. Ke, Y.-H.; Ju, Y.-M. (2015): Two rare ophiocordycipitaceous fungi newly recorded in Taiwan. *Botanical Studies* 2015, 56:30 doi:10.1186/s40529-015-0110-x: 6 pp. (in English) ["Background: Ophiocordycipitaceae is a highly diverse fungal family parasitizing a wide range of arthropods and hypogeous fungi. We collected two ophiocordycipitaceous species previously unknown in Taiwan: one emerged from hypogeous fruiting bodies of an *Elaphomyces* fungus and the other was associated with dragonflies (*Planaeschna* sp.). Results: Based on gross morphology, microscopic fea-

tures, ITS sequences, and hosts, the two ophiocordycipitaceous fungi were identified as *Tolypocladium japonicum* and *Ophiocordyceps odonatae*. We isolated axenic cultures of these two fungi, and their anamorphs were obtained. The simplicillium-like anamorph of *T. japonicum* is described herein for the first time. The anamorph of *O. odonatae* produce conidia holoblastically in sympodial sequence and is assignable to *Hymenostilbe*. A dichotomous key to the species of Ophiocordycipitaceae reported in Taiwan is provided. Conclusion: A thorough literature study indicates that the two fungi reported herein have rarely been collected. Our identifications of *T. japonicum* and *O. odonatae* agree well with descriptions in the literature and are highly supported by DNA sequence analysis." 15336. Khelifa, R. (2015): Does water intake after oviposition indicate the end of oviposition and egg depletion in Odonata females? *International Journal of Odonatology* 18(3): 225-231. (in English) ["Oviposition in odonate females is usually considered finished when the female leaves the oviposition site. However, considering that many species lay their eggs within a set of bouts it is difficult to distinguish between the end of the oviposition bout and the end of the oviposition episode because the females can change the oviposition site from one bout to another. In this study, post-oviposition drinking is suggested as behavioural indicator not only for the end of an oviposition episode but also for egg depletion in females, as investigated in 11 species from five families. This behaviour comprises water intake that the female performs at the end of oviposition by dipping the mouthparts in the water a few times before leaving the oviposition site. The role of downward bending of the abdomen displayed during water intake is also discussed." 15337. Khelifa, R.; Guebailia, A.; Mahdjoub, H.; Aouaouche, M.S.; Houhamdi, M. (2015): Aspects of life history of *Platycnemis subdilatata* (Zygoptera: Platycnemididae) in Northeast Algeria. *International Journal of Odonatology* 18(4): 317-327. (in English) ["The determination of seasonal regulation is important to understand how species have adapted to their local environmental conditions. In this study, we investigate the life history of a North African endemic damselfly, *Platycnemis subdilatata*, in a northeast Algerian population. We combined field and laboratory investigations to assess the embryonic development, larval growth, emergence pattern and adult flight season. The embryonic development was direct and asynchronous, with 50% of all eggs hatching after three weeks of egg laying and a hatching period ranging from 13 to 51 days. Hatching success was 48.8%, and the causes of hatching failure were infertility and unhatchability. Larval population structure was quite asynchronous during the winter and less so before emergence. The occurrence of larval diapause is improbable due to the increase of the proportion of the last larval stadium in late winter. Emergence was asynchronous with half of the larval population (EM50) emerging after 44 days within an emergence season of 122 days. Sex ratio at emergence was slightly female biased (50.6%). The flight season lasted 133 days starting from early May. The species reached its sexual maturity after six and seven days of emergence in male and female, respectively. Lifespan was not significantly different between sexes with a mean of 7.75 ± 6.45 days (\pm SD). Our results suggest that the species is univoltine with a typical summer species life history." (Authors)] Address: Khelifa, R., Dept of Biology, Faculty of Biological and Agricultural Sciences, University of Tizi Ouzou, Tiz, Algeria. E-mail: rassimkhelifa@gmail.com

15339. Klecka, J. (2015): Aquatic insects of a lowland rainforest in Papua New Guinea: assemblage structure in relation to habitat type. *Biologia* 70(12): 1621-1630. (in English) ["Papua New Guinea is one of the most valuable tropical regions but ecological research of its freshwater invertebrates has been lacking. The goal of this paper is to evaluate the species richness, diversity and structure of aquatic insect assemblages in different habitats in the Wanang River catchment in a well-preserved lowland rainforest. Assemblage structure was studied on two spatial scales - in

different habitats (river, streams and stagnant pools) and in three mesohabitats in the river (slow and fast sections and submerged wood). The results show that headwater streams had the highest morphospecies diversity, while the river had the highest insect abundance. Slow and fast sections of the river differed both in terms of insect abundance and diversity. Furthermore, a number of unique wood-associated species was found on submerged wood. The most notable feature of the assemblage structure was scarcity of shredders and dominance of predators. However, predatory beetles, bugs and dragonfly larvae exhibited contrasting habitat preferences. This study shows that Papua New Guinean lowland rainforests host diverse and distinctly structured freshwater insect assemblages." (Author) Taxa - including Odonata - are treated at the family level.] Address: Klecka, J., Laboratory of Integrative Ecology, Institute of Entomology, Biology Centre of the Academy of Sciences of the Czech Republic v.v.i., Branišovská 31, 37005 České Budějovice, Czech Republic

15340. Knorp, N.E.; Dorn, N.J. (2016): Mosquitofish predation and aquatic vegetation determine emergence patterns of dragonfly assemblages. *Freshwater Science* 35(1): 114-125 (in English) ["Both site-selective oviposition and interactions following colonization can play a role in structuring communities, but the relative importance of each has not been well studied for many animals. We manipulated the presence of a small-bodied fish predator (Eastern Mosquitofish, *Gambusia holbrooki*) and submerged aquatic vegetation (SAV; *Utricularia* spp.) in 24 mesocosms (n = 6 replicates, 4 treatments) to determine the effects of predators and habitat structure on dragonfly oviposition and naiad success. Adults did not avoid ovipositing in mesocosms with mosquitofish predators, but some species did select for or against SAV. No dragonfly naiads emerged from mesocosms with mosquitofish that lacked SAV. In treatments with SAV, total emergence was almost 3× higher in mesocosms without mosquitofish than mesocosms with mosquitofish. Oviposition patterns generally could not account for emergence patterns in the mesocosms, suggesting that libellulid dragonfly production can be severely limited by postcolonization interactions with mosquitofish. The dominant species emerging from the 3 treatments with naiad success varied consistently, a result suggesting that emerging assemblage composition was altered primarily by tolerances to mosquitofish/interspecific interactions. In mesocosms with SAV, the emerging assemblages were more species rich and more similar in the absence than in the presence of mosquitofish. We suggest that stochastic postcolonization egg or early-naiad survival may account for some assemblage variation in the presence of an efficient stage-specific predator like mosquitofish. This assemblage of libellulids appears to be filtered primarily according to vulnerability to fish predators, with SAV serving to reduce intensity of postcolonization interactions." 15341. Koch, C. (2015): Lifetime egg production of captive libellulids (Odonata). *International Journal of Odonatology* 18(3): 193-204. (in English) ["The estimation of lifetime egg production (LEP) is a central question in ecology, since the number of eggs produced determines the potential size of the following generation. In this study, I tried to obtain a rough estimation of the LEPs in libellulids in outdoor cages. The main questions were: (1) does hand feeding influence females' life history traits; (2) how long is the maturation period and the lifespan; (3) does the quality/quantity of eggs vary with female age or size; and (4) how many eggs do females lay in their lifetime? I installed two outdoor cages and kept individually marked specimens of *Orthetrum coerulescens* and *Sympetrum striolatum* under semi-natural circumstances. *Orthetrum coerulescens* had a longer life span in hand-fed specimens compared to not hand-fed. The maturation period, number of clutches, clutch size, egg circumference, and LEP did not differ between hand-fed and not hand-fed specimens. The median maturation period was shorter in *O. coerulescens* (24 days hand-fed; 20 days not hand-fed) than in *S. striolatum* (47 days, all hand-fed). The mortality during the maturation period was high in both studied species (*O. coerulescens* 81.48%, *S. striolatum* 89.16%). *Orthetrum coerulescens* had a shorter median life span than *S. striolatum*. The quality/quantity of eggs did not correlate with females' age and size. *Orthetrum coerulescens* had a mean calculated lifetime egg production of 3081 eggs per specimen and *S. striolatum* 1041 eggs per specimen. The data pertain to outdoor cage experiments (a reduced spectrum of prey, no long flights possible, no predators present). Nevertheless, they may provide a very rough estimation of LEP for two libellulid species." 15342. Kok, J.M.; Chahl, J.S. (2015): Effects of uneven stroking on the aerodynamic efficiency of a dragonfly-inspired wing-actuation system. *AIAC16: 16th Australian International Aerospace Congress*. Barton, ACT: Engineers Australia, 2015: 310-317. (in English) ["In this paper, we investigate the effects of using an uneven upstroke to downstroke motion on the aerodynamic efficiency of a dragonfly inspired flapping wing system. Our results show that for a system without elasticity, the highest aerodynamic efficiencies ($L/P = 0.185$) were observed using near symmetrical upstrokes to downstroke profiles ($\xi = 0.52$), but with an optimized pitching profile ($\alpha_{\text{pitch}} = 8\pi/12$, $\alpha_0 = 4\pi/12$). We then modeled the system with elasticity. In systems with low elasticity ($\lambda < 1.0$), the benefits of uneven stroking were minimal with percentage improvements in aerodynamic efficiency with the use of uneven stroking of less than 2%. However, in systems dominated by elastic forces ($\lambda < 2.0$), the improvements in aerodynamic efficiency can be as high as 35%." (Authors)] Address: Kok, J.M.,

15343. Koli, V.K.; Bhatnagar, C.; Shekhawat, D.S. (2015): Diversity and species composition of odonates in southern Rajasthan, India. *Proceedings of the Zoological Society* 68(2): 202-211. (in English) ["The study was conducted in south Rajasthan to explore diversity and species composition of Odonata from January 2013 to June 2013. Odonates were sampled from 13 localities i.e., Pichola lake, Udaisagar lake, Badi lake, Ghasa lake, Menar lake, Badwai lake, Rup sagar lake, Roli todgarh Wildlife Sanctuary, Sitamata Wildlife Sanctuary, Karmoi river stream in Sitamata WLS, College campus, Rajsmand lake and Meja dam. During the study period, a total of 1,290 individuals from 8 families and 54 species were recorded. 4 families and 28 species were related to Anisoptera, while 4 families and 26 species belonged to Zygoptera. Suborder Zygoptera were represented by the families Chlorocyphidae, Coenagrionidae, Lestidae and Platycnemididae, and suborder Anisoptera by the Aeshnidae, Gomphidae, Libellulidae and Macromiidae. Libellulidae was the largest family with 24 species, while the most dominant species was *Brachythemis contaminata* (21.80 %). *Orthetrum chrysis* and *Lestes* sp. were found randomly distributed in the study area, while other were aggregated and showed habitat preference." 15344. Kolozsvári, I.; Szabo, L.J.; Dévai, G. (2015): Dragonfly assemblages in the upper parts of the River Tisza: A comparison of larval and exuvial data in three channel types. *Acta Zoologica Academiae Scientiarum Hungaricae* 61(2): 189-204. (in english) ["We studied dragonfly assemblages in the Ukrainian section of the River Tisza, which still shows several natural (unregulated) properties. In 2010 and 2011 larvae and exuviae were collected in the vicinity of the villages Vilok, Nove Szelo, Tiszobikeny and of the towns Vinohragyiv and Huszt. We collected our samples from 8 sites in the main channel, 2 sites in side channels and 3 sites in two dead channels. We collected 255 larvae and 1587 exuviae [*Gomphus vulgatissimus*, *Stylurus flavipes*, *Onychogomphus forcipatus*, *Ophiogomphus cecilia*, *Soma-tochlora metallica*, *Calopteryx splendens*, *Platycnemis pennipes*, and *Sympecma fusca*]. We compared the species composition of dragonflies in the three habitats. In the case of larvae in the main channel *G. vulgatissimus* (48.0%), *C. splendens* (29.6%) and *O. forcipatus* (20.8%) dominated, while in the oxbow channels *C. splendens* (49.5%) and *P. pennipes* (23.7%) were found most frequently. In the side channels *G. vulgatissimus*, *O. forcipatus* and *C. splendens* were the most frequent species. *S. flavipes* appeared only in the main and side channels, while *S. metallica* and *S. fusca* were only detected in the oxbow channels." 15347. Koparde, P.; Mhaske, P.; Patwardhan, A. (2015): Habitat correlates of Odonata species diversity in the northern Western Ghats, India. *Odonatologica* 44(1/2): 21-43. (in English) ["Sixty-two localities from Sahyadri Tiger Reserve, Maharashtra State, India, were surveyed for habitat correlates of Odonata diversity. Proximate habitat variables (canopy cover, area of water spread on transect, and altitude) and broad scale environmental variables derived from climate database were used. Seventy species were recorded during the survey. *Vestalis apicalis* was found to be the most abundant species. Multiple regression analysis failed to resolve relationship among variables. Proximate habitat variables, except altitude, showed slightly higher contribution in shaping species richness and diversity than broadscale habitat variables. Canonical correspondence analysis based on species abundance data and multiple variables suggested that canopy cover and area of water on the transect are driving species assemblages. Almost all of the Western Ghats endemics recorded during the survey were found to be associated with high canopy forests and streams, suggesting the critical habitat requirement of these species. The study provides baseline and local habitat association data on Odonata, which can be used as evidence in the conservation of the Sahyadri Tiger Reserve corridor which is under threat of forest felling." 15348. Koskinen, J. (2015): Dragonfly communities of North Karelian forest lakes and ponds. M.Sc. Thesis, Department of Biology, University of Eastern Finland: 67 pp., 6 Appendices (in English, with Finnish summary) ["The goal of this thesis is to survey the dragonfly communities of small Southern Boreal forest ponds. Different dragonfly species exhibit different survival strategies against fish predation and the risk of drought and seasonal change. They also differ in the length of larval period. This should lead to different dragonfly community structures in ponds that are fishless compared to ponds that contain fish, and in ponds that are permanent or ephemeral. The heterogeneity and diversity of vegetation is known to be important for dragonfly diversity. The effects of fish predation on dragonfly community structures, abundance and species composition have been studied earlier, but much remains to be studied. Study sites, permanent, semipermanent and ephemeral ponds, both fish-inhabited and fishless, were selected by consulting of Greater Crested Newt (*Triturus cristatus*) research team. Study material was collected from forested ponds in Joensuu and Tohmajärvi municipalities in North Karelia, Eastern Finland. The larvae and exuviae data was collected during summer 2013. Specimens were identified in laboratory and finally used as community data. Environmental variables, such as architectural diversity of vegetation, were also measured. General dragonfly diversity index (Shannon's) and number of species was higher in ponds that contained fish than in ponds that did not. Area of the sampling sites did not correlate significantly with the number of individuals or species. The diversity of vegetational architecture also had a correlation with species richness and odonate Shannon's diversity. The community structures differed clearly between fishless and fish-inhabited ponds. The presence of fish, the ephemerality-permanence of the ponds and the vegetational diversity were all found to explain community structures. The presence of *Sphagnum* spp. peat mosses, and dwarf shrubs were also a frequent factor in community structures. Decoupling the presence of fish from other biotic and abiotic factors in research done in situ remains problematic."] (Author) Address: not stated

15349. Kosterin, O.E. (2015): *Onychargia priydak* sp. nov. (Odonata, Platycnemididae) from eastern Cambodia. *International Journal of Odonatology* 18(2): 157-168. (in English) ["*Onychargia priydak* sp. nov. is described from eastern Cambodia. The new species co-occurs with the widespread *Onychargia atrocyana* Selys, 1865 in the same region. Its males differ from those of *O. atrocyana* by a larger paraproct, which are longer than the cerci, and a bright white pruinescence on thorax, femora and the two first abdominal segments. This is the second species in the genus *Onychargia* Selys, 1865. *Onychargia vittigera* Selys, 1865 is synonymised with *O. atrocyana*; *Onychargia indica* Sahni, 1964 does not belong in the genus *Onychargia*."] (Author) Address: Kosterin, O.E., Institute of Cytology and

15355. Kosterin, O.E. (2015): On the Odonata of North Kazakhstan Province. I. First data on Petropavlovsk. IDF-Report 86: 1-28. (in English) ["The fauna of Odonata of the environs of Petropavlovsk, North Kazakhstan, was for the first time examined on two short trips in late June and mid August 2015. Thirty five species were revealed. *Coenagrion ecornutum* was recorded in Kazakhstan for the first time, *Gomphus vulgatissimus* the second time and *Stylurus flavipes* the third time. Range expansion of *C. ecornutum* is discussed. Comparison is attempted of the known local Odonata faunas of the environs of Petropavlovsk, Omsk and Novosibirsk cities residing at the same latitude in the West Siberian Lowland. The Petropavlovsk fauna is very close to that of Omsk. The earlier published Kazakh records of *G. vulgatissimus* and *S. flavipes* are clarified and corrected. Breeding of *Aeshna viridis* in Ishim River (lacking

water soldier) is supposed." (Author)] Address: Kosterin, O.E., Institute of Cytology and Genetics, Siberian Branch, Russian Academy of Sciences, Lavrentiev Ave 10, 630090 Novosibirsk, Russia. E-mail: kosterin@bionet.nsc.ru

15356. Kümmerlen, M.; Schmalz, B.; Cai, Q.; Haase, P.; Fohrer, N.; Jahnig, S.J. (2015): An attack on two fronts: predicting how changes in land use and climate affect the distribution of stream macroinvertebrates. *Freshwater Biology* 60(7): 1443-1458. (in English) ["1. Global environmental change entails not only climatic alterations, but also changes in land use. Freshwater ecosystems are particularly sensitive to both of these changes, and their sustainable management requires better information on likely responses. 2. To examine the effects of climate and land use on the freshwater community, the distributions of stream macroinvertebrates of the Changjiang catchment in southeast China were modelled. The present distributions of 72 taxa were predicted using environmental variables generated by regional climate, land-use and hydrological models. 3. Hydrological predictors, sensitive to both climate and land use, were the most relevant predictors in the species distribution models (SDMs), followed by land use. 4. The stream macroinvertebrates' distributions were then projected for the period 2021 to 2050 using three different future scenarios: (i) climate change, (ii) land-use change and (iii) climate and land-use change combined. 5. Land-use change was predicted to have the strongest negative impact on the community, with reductions in local richness (20%), predicted diversity (0.3%) and range size (25%) and a general shift towards higher altitudes (+12%). The climate-change scenario had a negative effect on predicted diversity (0.1%) and resulted in a moderate altitudinal shift (+3%) along with increased richness (+15%) and range size (+19%). In the combined scenario, climate and land-use changes counterbalanced each other to a certain degree, but had an overall detrimental effect. 6. The results underscore the high relevance of land-use change in future distribution predictions, exemplify the possible effect of interactions between land use and climate on hydrology and indicate how such responses can vary among freshwater taxa. The model also allows the detection of key environmental variables, the identification of vulnerable species and the definition of their potential distributions. This information is essential to establishing effective management and conservation strategies and gives a more comprehensive insight into the possible effects of global environmental change on freshwater ecosystems." 15364. Lambret, P.; Besnard, A.; Matushkina, N. (2015): Plant preference during oviposition in the endangered dragonfly *Lestes macrostigma* (Odonata: Zygoptera) and consequences for its conservation. *J. Insect Conserv.* 19(4): 741-752. (in English) [Marais du Vigueirat, Camargue (Southern France); "Biotic and abiotic features impact the breeding success of animals and thereby induce selection pressures for habitat selection. Little is known about the plant selection by predatory insects which lay their eggs within plants. In previous work, we have highlighted that during oviposition males of *Lestes macrostigma*—an endangered dragonfly species—prefer to land on *Bolboschoenus maritimus* and dead shoots of *Juncus maritimus* but disfavour living shoots in that species, and that females seem to prefer dead material during substrate examination. In this study we assessed behavioural preference in females during substrate examination, substrates suitability for oviposition, the effort females had to make to lay their eggs and their resulting oviposition rate. We show *L. macrostigma* has a preference for *B. maritimus* and, albeit to a lesser extent, for dead substrates. No clear trend appeared regarding substrate suitability. Females had to

make a greater effort to lay an egg within living shoots of *J. maritimus*. By contrast, this effort was less in *B. maritimus* and dead shoots of *J. maritimus* and the oviposition rates were higher for these two types of substrate. We hypothesize that these preferences are relevant in the selection of oviposition substrates which are more likely to be flooded earlier by rainfall, reducing risk of egg desiccation and increasing hatching success. With regard to conservation, *B. maritimus* and *J. maritimus* should be encouraged by wildlife managers especially in habitat restoration programs which aim to increase the number of suitable breeding sites for the species." 15365. Lambret, P.; Besnard, A.; Matushkina, N. (2015): Initial preference for plant species and state during oviposition site selection by an odonate. *Entomological Science* 18: 377-382. (in English) [National Natural Reserve of the Marais du Vigueirat, Camargue (southern France), at the Baisse des Marcells; "Endophytic egg-laying odonates use an ovipositor to insert their eggs inside plant tissues. Before egg deposition, oviposition site selection consists of two crucial steps: (i) the initial choice, typically decided in species that oviposit in tandem within vertical substrates by the male when landing and then by the female by staying on the substrate or flying to another; and (ii) the insertion site choice, made by the female who uses her ovipositor to palpate the substrate. Some odonates prefer to deposit their eggs within specific plant species. Some are able to discriminate between living and dead substrates during the initial choice. However, the extent to which odonates discriminate among distinct plant species during the initial choice is unknown. We studied the initial site preference in *L. macrostigma* to determine whether the males and/or females show a distinct preference among five types of shoots when landing on or when palpating the substrate, respectively. Male *L. macrostigma* preferred to land on *Bolboschoenus maritimus* and dead *Juncus* spp. When focusing on *J. maritimus*, females preferentially palpated the substrate when the male landed on dead shoots. We suggest that the male preference for these substrates is consistent with that of the female during insertion site choice but also during egg deposition. Such behaviour should reduce the duration of oviposition, with benefits of reducing the predation risk and increasing available time for foraging. The advantage in preferring these substrates should be linked to a selection pressure acting on egg development and/or survival." 15366. Le Rouzic, A.; Hansen, T.F.; Gosden, T.P.; Svensson, E.I. (2015): Evolutionary time-series analysis reveals the signature of frequency-dependent selection on a female mating polymorphism. *The American Naturalist* 185(6): E182-E196. (in English) ["A major challenge in evolutionary biology is understanding how stochastic and deterministic factors interact and influence macroevolutionary dynamics

in natural populations. One classical approach is to record frequency changes of heritable and visible genetic polymorphisms over multiple generations. Here, we combined this approach with a maximum likelihood-based population-genetic model with the aim of understanding and quantifying the evolutionary processes operating on a female mating polymorphism in *Ischnura elegans*. Previous studies on this colour-polymorphic species have suggested that males form a search image for females, which leads to excessive mating harassment of common female morphs. We analyzed a large temporally and spatially replicated data set of between-generation morph frequency changes in *I. elegans*. Morph frequencies were more stable than expected from genetic drift alone, suggesting the presence of selection toward a stable equilibrium that prevents local loss or fixation of morphs. This can be interpreted as the signature of negative frequency-dependent selection maintaining the phenotypic stasis and genetic diversity in these populations. Our novel analytical approach allows the estimation of the strength of frequency-dependent selection from the morph frequency fluctuations around their inferred long-term equilibria. This approach can be extended and applied to other polymorphic organisms for which time-series data across multiple generations are available." 15367. Leon, E.J.; Olguín, P.F.; Beltzer, A.H. (2015): Aportes al conocimiento de la dieta del mirasol chico (*Ixobrychus involucris*) (Aves: Ardeidae) en el valle de inundación del río Paraná Medio, Argentina. *Revista FABICIB* 19: 65-74. (in Spanish, with English summary) ["Contributions to the knowledge of the diet of Least Bittern (*Ixobrychus involucris*) (Aves: Ardeidae) flooding in the valley of the middle Paraná river, Argentina. The first input on the diet of *Ixobrychus involucris* in the valley of the Middle Paraná River flood, Argentina are presented. Stomach contents of 13 individuals captured with mist nets and washings were analyzed performed stomach. The trophic diversity stomach ranged between 0.22 and 2.89. The cumulative trophic diversity was 1.58. The trophic spectrum showed Insecta as the most important entity (Odonata, Coleoptera, Hemiptera and Orthoptera). The IR showed: Insects = 10450; Fish and Arachnids = 140. To prey size 55% were insects, the class interval comprising 31-40 mm. In terms of niche breadth: Spring = 0.10, Summer = 0.19, = 0.17 Autumn and Winter = 0.14. Feed efficiency corresponded to: Spring = 88.9; Summer = 91.45; Autumn and Winter = 91.04 = 88.92. For food selectivity, the calculation was not significant. The daily rhythm of feeding activity can display a bimodal pattern with two peaks of activity." 15368. Lorenzo-Carballa, M.O.; Ferreira, S.; Sims, A.M.; Thompson, D.J.; Watts, P.C.; Cher, Y.; Damoy, V.; Evrard,

A.; Gelez, W.; Vanappelghem, C. (2015): Impact of landscape on spatial genetic structure and diversity of *Coenagrion mercuriale* (Zygoptera: Coenagrionidae) in northern France. *Freshwater Science* 34(3): 1065-1078. (in English) ["Loss and fragmentation of habitat is a current main cause of biodiversity loss in freshwater habitats. Odonates (dragonflies and damselflies) depend on these habitats to complete their development. Fragmentation may be a particular threat for odonates because it generates a network of small habitat patches within which populations could suffer from isolation and loss of genetic diversity. The southern damselfly *Coenagrion mercuriale* is categorized on the IUCN red list as Near Threatened, largely because of population fragmentation and demographic declines associated with changes in land use. Small populations at the margin of this species' range are of particular concern because they would be prone to detrimental effects of habitat fragmentation if this species were a poor disperser. We sampled *C. mercuriale* in 16 habitat patches (localities) at 4 main sites in the department of Pas-de-Calais in northwestern France to quantify factors that affect dispersal and genetic diversity. Specimens were genotyped at 12 microsatellite loci to quantify genetic diversity, genetic differentiation, and the potential effect of landscape variables on genetic differentiation, and to detect any potential source-sink structure. Habitat separation had a limiting effect on dispersal by *C. mercuriale*, resulting in 3 main genetic clusters and weak divergence at the main site of Vallée de la Course. Genetic differentiation was low in each main site, implying that the localities within sites were connected at scales of up to ~2 km, albeit with some evidence for isolation at the more isolated localities. Given the degree of isolation of some areas and a lack of apparent genetic mixing in the intervening populations, any movement among the most distantly separated sites must have occurred some time ago. We identified barriers to dispersal, such as woodland, but detecting an unambiguous effect of certain variables, such as urbanization, was difficult because many landscape features were highly correlated." 15369. Louboutin, B.; Nicolas, M.; Gautier, C. (2015): Redécouverte d'*Ischnura graellsii* en France (Odonata : Coenagrionidae). *Martinia* 31(2): 91-102. (in French, with English summary) ["*Ischnura graellsii* was rediscovered in July 2015, in abundance at two man-made ponds located in the township of Sainte-Léocadie (Pyrénées-Orientales department), in the French Cerdanya. This is for this species, of which the identity had been suspected basing on pictures made in 2013 and 2014, the first observation after the previous quotation by Morton in the Pyrénées-Atlantiques department in 1913. Among the Odonata present on the site, several species, including *Erythromma viridulum* reached here their highest altitude in France (1260 m a.s.l.). In this paper are presented the context of this finding, the features of the site, the odonatological assemblage and the distribution of both *I. elegans* and *I. graellsii* from either side

of the eastern Pyrenees. This French population represents clearly an extension of the nearby Spanish Catalan populations in our country. It is doubtful they can extend more north beyond the special Cerdanyan climate." 15370. Luiz, L.F.; Contrera, F.A.L.; Neckel-Oliveira, S. (2015): Diet and tadpole transportation in the poison dart frog *Ameerega trivittata* (Anura, Dendrobatidae). *The Herpetological Journal* 25(3): 187-190. (in English) ["Diet and transportation of tadpoles by *Ameerega trivittata* was studied in the eastern Amazon basin. A total of 56 specimens (48 males and 8 females) were sampled, 44 out of which had quantifiable stomach contents. Forty males were recorded to carry between 1 and 18 tadpoles. Forty pools were measured and sampled for tadpoles and odonate naiads, a putative tadpole predator. Myrmicine ants predominated in the diet of males, putatively leading to higher concentrations of alkaloids beneficial during tadpole transport. No relationship was found between male size and the number or size of tadpoles transported, and between pool size and tadpole abundance. The number of tadpoles in the pools was negatively related to the abundance of odonate naiads." 15372. Maneechan, W.; Promm, T.O. (2015): Diversity and distribution of aquatic insects in streams of the Mae Klong watershed, western Thailand. *Psyche* Volume 2015 (2015), Article ID 912451: 7 pp. (in English) ["The distribution and diversity of aquatic insects and water quality variables were studied among three streams of the Mae Klong Watershed. In each stream, two sites were sampled. Aquatic insects and water quality variables were randomly sampled seven

times in February, May, September, and December 2010 and in January, April, and May 2011. Overall, 11,153 individuals belonging to 64 families and nine orders were examined. Among the aquatic insects collected from the three streams, the order Trichoptera was most diverse in number of individuals, followed by Ephemeroptera, Hemiptera, Odonata (11.3%), Coleoptera, Diptera, Plecoptera, Megaloptera, and Lepidoptera. The highest Shannon index of diversity of 2.934 and 3.2 was recorded in Huai Kayeng stream and the lowest was in Huai Pakkok stream (2.68 and 2.62). The high diversity of insect fauna in streams is an indication of larger microhabitat diversity and better water quality conditions prevailing in the streams. The evenness value was recorded as high in most sites. The high species diversity and evenness in almost all sites indicated good water quality." (Authors) Taxa are treated at family level.] Address: Maneechan, W., Faculty of Liberal Arts and Science, Kasetsart University, Kamphaeng Saen Campus, Nakhon Pathom 73140, Thailand

15373. Manu, M.; Szekeley, L.; Oromulu, L.V.; Barbuceanu, D.; Honciuc, V.; Maican, S.; Fiera, C.; Purice, D.; Ion, M. (2015): Bucharest. In: J.G. Kelcey (ed.): *Vertebrates and Invertebrates of European Cities: Selected Non-Avian Fauna*. Springer New York: 257-322. (in English) ["Eight invertebrate 'groups' were investigated having a total of 503 species, which can be divided into two major categories: above ground and below ground. The above-ground groups are the Coleoptera (beetles), Lepidoptera (butterflies and moths), Odonata (dragonflies and damselflies), Orthoptera (grasshoppers and crickets) and Thysanoptera (thrips). The below-ground groups are the Acari—Mesostigmata (soil mites), Acari—Oribatida (beetle mites), Collembola (springtails) and Myriapoda—Diplopoda (millipedes) and Myriapoda—Chilopoda (centipedes) The study revealed different structural complexities of the invertebrate populations (including non-native species) in relation to three groups of factors, namely the habitat and ecological requirements of the species, the characteristic features of the urban environment (including pollution, soil types and the species composition and structure of the vegetation) and the morphology and dynamics of some of the invertebrate groups. Zoological surveys of Bucharest indicate that the city has a rich and interesting invertebrate fauna. There are some scientific studies concerning the impact of pollution on biodiversity in urban habitats and the legal framework to protect green spaces that are generally often neglected. Plans for the expansion and management of urban areas should be based on scientifically comprehensive, interdisciplinary research projects, which will, amongst other benefits, provide a complete inventory of the invertebrate species, which are an excellent group of biological indicators." 15374. Marchant, R.; Grant, T. (2015): The productivity of the macroinvertebrate prey of the platypus in the upper

Shoalhaven River, New South Wales. *Marine and Freshwater Research* 66(12): 1128-1137. (in English) ["The platypus, *Ornithorhynchus anatinus*, feeds almost exclusively on benthic macroinvertebrates, yet no attempt has been made to link its energy demands with the productivity of its benthic macroinvertebrate prey. In the upper Shoalhaven River, NSW, we estimated macroinvertebrate production (in 2009 and 2011) from benthic samples and recorded platypus diet (2009 only) from cheek pouch samples. Ephemeroptera, Trichoptera and Chironomidae were the most numerous of 6 major groups in both the cheek pouches and the benthic samples. Three other groups (Odonata, Coleoptera, Sphaeriidae) were much less abundant in the benthos, but Odonata were common in the cheek pouches. In both years the Ephemeroptera, Trichoptera and Chironomidae had levels of production that were an order of magnitude higher than those of the three other groups. Total macroinvertebrate production for the six groups varied from 7.8 (in 2009) to 13.1 (in 2011) g DW m⁻²y⁻¹. Previous estimates of field metabolic demand (FMD) of the platypus enabled calculation of the number that could be supported by a given level of production. The observed levels of production were sufficient to support 13-27 platypuses in 2009 and 22-45 in 2011 along a 1.5km reach of the river." 15375. Marinov, M.; Schmaedick, M.; Polhemus, D.; Stirnemann, R.L.; Enoka, F.; Fa'aumu, P.S.; Uili, M. (2015): Faunistic and taxonomic investigations on the Odonata fauna of the Samoan archipelago with particular focus on taxonomic ambiguities in the "Ischnurine complex". *International Dragonfly Fund Report* 91: 1-56. (in English, with Samoan summary) ["New faunistic data is provided on the Odonata inhabiting the three main islands within the Samoan archipelago, namely Savai'i, Upolu and Tutuila as well as the smaller islands of Aunu'u and the Manu'a group. The specimens collected or observed in the field were compared to samples from other nearby Pacific island groups such as Fiji and Tonga. This study makes important contributions towards resolving taxonomic issues regarding the *Ischnura* species described as endemic to Samoa and their relations to other *Coenagrionidae* genera. New diagnostic features for distinguishing between females of the endemic genera *Amorphostigma* and *Pacificagrion*, subspecies separation in the Pacific *Tramea transmarina* and distinguishing between Samoan *Hemicordulia* species are suggested. *Anaciaeschna melanostoma* is proposed as junior synonym of *A. jaspidea*. A possible new subspecies of *Lathrecista asiatica*, confined to the Samoan archipelago, is discussed. The validity of *Agriocnemis interrupta* as a separate species from *A. exsudans* is questioned. Pacific *Pseudagrion* is believed to be represented within the region by one species only, with separate subspecies in Fiji, Tonga and Samoa, although more specimens from Fiji are required to resolve this issue." Auckland 1072 New Zealand. E-mail: Milen.Marinov@mpi.govt.nz

15376. Marinov, M. (2015): The seven "oddities" of Pacific Odonata biogeography. *Faunistic studies in South-east Asia and Pacific island Odonata* 11: 1-58. (in English) ["The existing literature on the Odonata inhabiting the three large divisions of the Pacific Ocean (Micronesia, Melanesia, Polynesia) is revised taking into consideration earlier discussions on the species origin, historical faunistic records, various palaeogeographical models proposed for the area, general data on the biology and ecology of this insect order. Special emphasis is paid on the incomplete data set for the region and inconsistency of the exploration of this vast area. The taxonomy and fauna of the Pacific Odonata is far from complete which makes it very difficult to provide any plausible hypothesis on the biogeographical pattern that we observe today. The widely accepted view of long distance dispersal from a centre of origin as the only possible means for species to occupy remote oceanic island archipelagos is critically reviewed. There are seven phenomena in the current Odonata distribution that cannot be explained only by random gene transfer mediated by wind dispersal. Those are called "oddities", however, they are believed to be regularities of past geological events and modern day human associated activities within the Pacific. The rationale for each of them is explained in details and illustrated with distribution maps following the current taxonomy of the group. A new approach is suggested to tackle the question of the origin of the Pacific Odonata by relating the higher taxa distribution to the geological events and palaeontology of the families. It is not intended to be a new hypothesis yet before more systematic studies of the taxonomy and fauna of the group. Therefore, it is believed that the new method suggested here will increase the attention of the scientific community and will boost studies on this insect order within the Pacific Ocean. Discussion on its applicability is provided with attention to details that are difficult to be explained with the Pacific Odonata palaeontology as we know it for the moment." 15381. Martín, M.; Maynou, X. (2015): Evaluación del estado de amenaza de los odonatos (Insecta: Odonata) de Cataluña (España). *Boletín de la Sociedad Entomológica Aragonesa* 56: 161-172. (in Spanish, with English summary) ["An assessment of the threat status of the dragonflies (Insecta: Odonata) of Catalonia (Spain). We assessed the degree of threat or vulnerability of the 70 dragonfly and damselfly taxa recorded from Catalonia to date by analyzing more than 30,000 observational records from the *Oxygastra*

GEOC (Catalan Odonata Study Group) database that include information on distribution, abundances and breeding habitats. We used two independent methods of assessment: IUCN and IVOC (Vulnerability Index of the Odonata of Catalonia, based on Abellán et al. (2005)). For the first one we considered mainly the criteria related to size and fragmentation of the distribution areas of taxa and the possible evolution of the conservation status of their characteristic habitats. For the second, we took into account the six parameters included in the Vulnerability Index calculation, i.e. overall distribution of the taxon, degree of endemism, rarity, persistence, and rarity and threat to their reproductive habitats. Both methods showed some discrepancies in the assessment of the degree of threat for the different taxa due to differences in the criteria used, underlining their complementarity and reinforcing the assessment. Combining the results obtained by both methodologies resulted in a list of nine species threatened or highly vulnerable: *Coenagrion hastulatum*, *Aeshna isocetes*, *Gomphus graslinii*, *Onychogomphus costae*, *Cordulia aenea*, *Macromia splendens*, *Orthetrum nitidinerve*, *Sympetrum pedemontanum* and *Leucorhinia dubia*." 15383. Matheson, T.; Ball, O.; Pohe, S. (2015): *Tamea loewii* (Odonata: Libellulidae) on the move. *The Weta* 50(1): 10-17. (in English) ["*T. loewii* has recently become established in New Zealand, with a known distribution on the Aupouri Peninsula north of Kaitiaki. To determine whether the species has spread further south, the littoral zones of eleven central Northland lakes from Ahipara to Waipu were sampled. Searches for exuviae and adults of *T. loewii* were also conducted at each lake. Larval *T. loewii* were only found at the Uretiti sand pit lake near Ruakaka, south of Whangarei. Many exuviae and adults in flight were also observed at the lake, indicating the species is established there. This represents a substantial range expansion and is

the southernmost record of *T. loewii* to date." (Authors)] Address: Ball, O., NorthTec, Department of Applied and Environmental Sciences, Whangarei, New Zealand. E-mail: oball@northtec.co.nz

15384. Matsunami, M.; Kitano, J.; Kishida, O.; Michimae, H.; Miura, T.; Nishimura, K. (2015): Transcriptome analysis of predator- and prey-induced phenotypic plasticity in the Hokkaido salamander (*Hynobius retardatus*). *Molecular Ecology* 24(12): 3064-3076. (in English) ["Predator- and prey-induced phenotypic plasticity is widely observed among amphibian species. Although ecological factors inducing diverse phenotypic responses have been extensively characterized, we know little about the molecular bases of variation in phenotypic plasticity. Larvae of the Hokkaido salamander, *Hynobius retardatus*, exhibit two distinct morphs; the presence of their prey, *Rana pirica* tadpoles, induces a broad-headed attack morph, and the presence of predatory dragonfly nymphs (*Aeshna nigroflava*) [= *Aeshna crenata* Hagen, 1856] "induces a defense morph with enlarged external gills and a high tail. To compare the genes involved in predator- and prey-induced phenotypic plasticity, we carried out a de novo transcriptome analysis of Hokkaido salamander larvae exposed to either prey or predator individuals. First, we found that the number of genes involved in the expression of the defense morph was approximately five times the number involved in the expression of the attack morph. This result is consistent with the fact that the predator-induced plasticity involves more drastic morphological changes than the prey-induced plasticity. Second, we found that particular sets of genes were up-regulated during the induction of both the attack and defense morphs, but others were specific to the expression of one or the other morph. Because both shared and unique molecular mechanisms were used in the expression of each morph, the evolution of a new plastic phenotype might involve both the co-option of pre-existing molecular mechanisms and the acquisition of novel regulatory mechanisms." 15386. Mehdi, H.; Anwer, S.F.; Ahmad, A. (2015): Fluid structure interaction of flow around a pleated insect 2D airfoil at ultra low reynolds numbers. *International Journal of Research in Aeronautical and Mechanical Engineering* 3(3): 19-37. (in English) ["In this work, Numerical study of

Fluid Structure Interaction of uniform flow past a two dimensional pleated airfoil is carried out. When the wing interact with the air, it is subjected to both aerodynamic forces acting on the surface of the wing and the inertial force due to the acceleration or deceleration of the wing mass. The interaction between these inertial and aerodynamic forces resulted in wing deformation. The dynamics of a pleated insect wing subjected to aerodynamic loading is studied. The vortex induced vibration and forced vibration of a pleated flexible insect wing subjected to aerodynamic load is studied by using ANSYS-14 multi physics solver. The insect wing is of dragonfly (*Aeshna cyanea*) wing cross section. In the first phase of the work, fluid flow simulation at Reynolds Number-100, 200, 500, and 1000 will be performed with angle of attack 0° to 15° . The result from the CFD solver will be fed in the form of lift and drag forces are then fed into the ANSYS Workbench solver and one way Fluid Structure Interaction analysis is performed." 15387. Melfi, J.; Wang, Z.J. (2015): L27.00005: Uncontrolled stability in freely flying insects. *Bulletin of the American Physical Society* 60(21): 1 p. (in English) [Verbatim: One of the key flight modes of a flying insect is longitudinal flight, traveling along a localized two-dimensional plane from one location to another. Past work on this topic has shown that flying insects, unless stabilized by some external stimulus, are typically unstable to a well studied pitching instability. In our work, we examine this instability in a computational study to understand whether it is possible for either evolution or an aero-vehicle designer to stabilize longitudinal flight through changes to insect morphology, kinematics, or aerodynamic quantities. A quasi-steady wingbeat averaged flapping flight model is used to describe the insect. From this model, a number of non-dimensional parameters are identified. The effect of these parameters was then quantified using linear stability analysis, applied to various translational states of the insect. Based on our understanding of these parameters, we demonstrate how to find an intrinsically stable flapping flight sequence for a dragonfly-like flapping flier in an instantaneous flapping flight model.] Address: Wang, Z. 15388. Merzendorfer, H. (2015): Dragonfly hunting is based on predictive models. *J. Exp. Biol.* 218: 1278-1279. (in English) ["Mischiati, M., Lin, H.-T., Herold, P., Imler, E., Olberg, R. & Leonardo, A. (2015). Internal models direct dragonfly interception steering. *Nature* 517, 333-338." Verbatim: Goalkeepers doubtless need excellent responses to prevent the opposition from scoring that goal. However, exceptional responses are not enough. To reach and catch the ball at the right moment, the goalkeeper has to predict where the ball will end up and calculate where their movements will take them to capture the ball. This type of control has been found only in vertebrates so far. However, a recent study published in *Nature* by a team of researchers led by

Anthony Leonardo from the Howard Hughes Medical Institute, USA, has demonstrated that dragonflies that are in pursuit rely on internal models that predict the effects of movements of their own body and their target, like the goalkeeper catching the ball. Dragonflies are brilliant aeronauts that can hover, fly at high speed and perform agile manoeuvres to defend their territory, mate on the wing or chase prey. Their vision is also excellent: with their large eyes they can see in almost any direction. Usually they lurk on plants where they wait for prey insects to fly over. Once the prey is in focus, the dragonfly rapidly lifts off and manoeuvres to approach the prey at an angle from below, so that it can trap the victim with its capture legs. To analyse this type of hunt in more detail, the team filmed dragonflies in slow motion during pursuits. It became obvious that the dragonflies did not rely exclusively on their reactions, because they did not always respond to unexpected changes in the prey motion. Rather, they tried to align their elongated body with the flight path of their prey to approach and strike from below, minimizing the chances of being discovered. To do so, the head of the dragonfly moves independently from the body, so that the eyes can continuously focus on the prey while the body is aligned with the prey's flight path. The scientists then dissected the head movements in more detail. They set up a flight arena, which allowed them to record the paths of dragonflies and prey with high accuracy using high-speed cameras. They also placed micro-reflective markers on the head and body of the dragonflies to record the relative movements. Based on these data, they then calculated the angular position of the prey image on the dragonfly's eye. What they found was quite surprising, as the head motions turned out to compensate precisely for drift of the prey image on the eye that resulted from the dragonfly's own body movements and the anticipated motion of the prey. The high synchrony and precision of the timing of these head movements suggest that dragonflies use internal calculations to generate models that predict how body and prey movements will influence the position of the image on the dragonfly's eye, and how the head must then be moved to cancel out these effects: classical sensory feedback. This predictive system largely compensates for the dragonfly's own body movements and thus relieves the visual system to detect sudden prey manoeuvres, to which the dragonfly can respond by reactive control. Leonardo and his team have shown for the first time that invertebrates use internal models to predict the effects of their own body movements when targeting prey. The fact that all of the experiments were done under laboratory conditions where the prey's movements are more restricted may suggest that this predictive steering control could be dominated by reactive mechanisms in the wild, thus explaining why it had been overlooked for so long.] Address: Merzendorfer, H., Univ. 15389. Meyer, M.D.; Davis, C.A.; Dvoretz, D. (2015): Response of wetland invertebrate communities to local and landscape factors in North Central Oklahoma. *Wetlands* 35(3): 533-546. (in English) ["Invertebrates play an important role influencing wetland functions. Specifically, they

provide important food for many waterbirds and other wetland species. To better understand the role environmental factors play in influencing invertebrates, we examined the influence of local and landscape factors on invertebrate communities inhabiting depressional wetlands in Oklahoma. We sampled invertebrates from 58 wetlands during 2009 and 2010. Diversity and taxa richness increased as the season progressed and with vegetation complexity and cover. Diversity and richness decreased as water quality was impacted by nutrient and sediment loading. Local variables occurred more consistently in taxa models than landscape variables. Important local variables included wetland hydrology, vegetation complexity, and water quality, while important landscape variables included density and type of wetlands surrounding wetlands. Land-use practice was the least important landscape variable, but is an important variable due to potential relationships with local variables such as water quality. Low variation (12–26 %) explained by the pCCA suggests other variables may be influencing invertebrate communities, but an alternative explanation is that invertebrates are insensitive to environmental variation. These findings can guide both local management of wetlands and conservation strategies at the watershed or regional scale to benefit not only invertebrates but other wetland dependent species. ... Individual taxa analyses were conducted on taxa occurring in at least 20 % of the samples during both years. These taxa included "Enallagma"... For three taxa (*Callibaetis*, *Enallagma*, and *Ostracoda*), the negative binomial component of the model for sampling date was positive and the binomial component was negative indicating that as the season progressed, biomass of these taxa increased and the probability of the taxa being absent from wetlands decreased. In the models for *Cladocera* and *Enallagma*, the negative binomial for BVEG1 was significantly positive indicating that biomass of these taxa increased as vegetation complexity and submergent cover increased. ... *Enallagma* was less likely to occur at wetlands affected by poor water quality.... *Enallagma* biomass decreased with the amount of rangeland surrounding the wetland. ... *Enallagma*, *Anax*, *Berosus* larvae, *Callibaetis*, and *Physa* were associated with wetlands that contained high vegetation complexity and low turbidity and were located in landscapes characterized by a high occurrence of semi-permanent wetlands." 15390. Michels, J.; Gorb, S.N.; Reinhardt, K. (2015): Reduction of female copulatory damage by resilin represents evidence for tolerance in sexual conflict. *J. R. Soc. Interface* 12(104): 7 pp. (in English) ["Intergenomic evolutionary conflicts increase biological diversity. In sexual conflict, female defence against males is generally assumed to be resistance, which, however, often leads to trait exaggeration but not diversification. Here, we address whether tolerance, a female defence mechanism known from interspecific conflicts, exists in sexual conflict. We examined the traumatic

insemination of female bed bugs via cuticle penetration by males, a textbook example of sexual conflict. Confocal laser scanning microscopy revealed large proportions of the soft and elastic protein resilin in the cuticle of the spermatheca, the female defence organ. Reduced tissue damage and haemolymph loss were identified as adaptive female benefits from resilin. These did not arise from resistance because microindentation showed that the penetration force necessary to breach the cuticle was significantly lower at the resilin-rich spermatheca than at other cuticle sites. Furthermore, a male survival analysis indicated that the spermatheca did not impose antagonistic selection on males. Our findings suggest that the specific spermatheca material composition evolved to tolerate the traumatic cuticle penetration. They demonstrate the importance of tolerance in sexual conflict and genitalia evolution, extend fundamental coevolution and speciation models and contribute to explaining the evolution of complexity. We propose that tolerance can drive trait diversity." (Authors) The paper includes references to Odonata.] Address: Michels, J., Department of Functional Morphology and Biomechanics, Institute of Zoology, Christian-Albrechts-Universität zu Kiel, Am Botanischen Garten 1 – 9, 24118 Kiel, Germany

15391. Michimae, H.; Tezuka, A.; Emura, T.; Kishida, O. (2015): Environment-dependent trade-offs and phenotypic plasticity in metamorphic timing. *Evolutionary Ecology Research* 16: 617-629. (in English) ["Background: Fitness trade-offs of plastic traits between alternative environments are a prerequisite for the evolution of phenotypic plasticity; however, the costs associated with plastic traits have yet to be determined. Most empirical studies have assessed the costs of plastic traits by investigating just two environments (to elicit plasticity), and only one or two environments to evaluate the consequences of plasticity. In contrast, in nature, organisms are constantly subjected to multiple environments, and the expression and magnitude of the costs of plastic traits are occasionally context-dependent. Objective: Analyse the costs of plastic traits across multiple environments. Methods: We determined the benefits and costs of two plastic responses (predator- and prey-induced morphologies) of larvae of the salamander *Hynobius retardatus* to larval survival, time to metamorphosis, and body size at metamorphosis in three different environments [using tadpoles of an anuran frog as prey, larvae of a predatory dragonfly (*Aeshna nigroflava* = *A. crenata*), or no change agent (conspecific larvae only)]. Results: The benefits of the alternative phenotypes were evident in the two inducing environments, but the costs were greater or more easily detected in crossover environments. The trade-offs appeared in combinations in the crossover environments, and thus were context-dependent. Conclusions: The cross-environmental costs of plastic traits are necessary for the evolution of phenotypic plasticity. Our findings highlight the importance of measuring the costs and benefits of plastic traits across multiple environments." 15392. Mikolajewski, D.J.; Rösen, L.; Mauersberger, R.; Johansson, F.; Rolff, J. (2015): Relaxed predation results in reduced phenotypic integration in a suite of dragonflies. *Journal of Evolutionary Biology* 28(7): 1354-1363. (in English) ["While changes in magnitude of single traits responding to selective agents have been studied intensively, little is known about selection shaping networks of traits and their patterns of co-variation. However, this is central for our understanding of phenotypic evolution since traits are embedded in a multivariate environment with selection affecting a multitude of traits simultaneously rather than individually. Here, we investigate inter- and intraspecific patterns of trait integration (trait correlations) in the larval abdomen of dragonflies as a response to a change in predator selection. Species of the dragonfly genus *Leucorrhinia* underwent a larval habitat shift from predatory fish to predatory dragonfly dominated lakes with an associated relaxation in selection pressure from fish predation. Our results indicate that the habitat-shift induced relaxed selection pressure caused phenotypic integration of abdominal traits to be reduced. Intraspecific findings matched patterns comparing species from both habitats with higher abdominal integration in response to predatory fish. This higher integration is probably a result of faster burst swimming speed. The abdomen holds the necessary morphological machinery to successfully evade predatory fish via burst swimming. Hence, abdominal traits have to function in a tight coordinated manner, since maladaptive variation and consequently non-optimal burst swimming would cause increased mortality. In predatory dragonfly dominated lakes no such strong link between burst swimming and mortality is present. Our findings highlight the importance of studying multivariate trait relationships as a response to selection for understanding patterns of phenotypic diversification." 15393. Mikolajewski, D.J.; Conrad, A.; Joop, G. (2015): Behaviour and body size: plasticity and genotypic diversity in larval *Ischnura elegans* as a response to predators (Odonata: Coenagrionidae). *International Journal of Odonatology* 18(1): 31-44. (in English) ["Phenotypic plasticity represents an adaptive tool in organisms including odonates to cope with heterogeneous environmental conditions. However, while some odonate species can occupy various changing habitats, other species are adapted to a narrow range of environmental conditions. Commonly, behavioural modifications are applied to avoid detection and encounters with predators. But reduced behavioural activity results in decelerated growth and reduced body size, a key fitness attribute in odonates. Using larval *Ischnura elegans* we quantified predator induced plastic behavioural reaction norms in order to manifest variance, and by this evolvability of larval behavioural plasticity. In addition we test for potentially underlying genetic correlations of behavioural traits with body size. Our results show that there is large genotypic variance in plastic reaction norms. Furthermore, no present genetic

constraints between behaviour and body size were detected, suggesting potential for independent optimisation of behaviour and body size across environments. Our data indicate that independent phenotypic plasticity in behaviour and body size might enable species to occupy a wide range of environmental conditions." (in English) ["In this paper we present the concept, fabrication, and testing of resonant cantilever wings for monolithic micro aerial vehicles (MAVs). Combining new analytical and computational fluid dynamic work to determine the resonant mode, forces, and power of resonating curved cantilevers, we present a framework to calculate and optimize robot designs for certain figures of merit (i.e., greatest excess power, smallest size, and fastest time for a swarm to search a volume). The optimization results reveal promising designs on scales ranging from fruit flies to dragonflies with the optimal MAV having a maximum continuous travel speed of 2 m/s, 10 mm wing length, and 9 mg total mass. We then fabricate curved cantilever wings to test the theoretical model, which confirm the resonant frequency, resonant mode shape, power dissipated, and net force generated. This work is the first demonstration of asymmetric force from a symmetric flapping cycle and of the feasibility of curved cantilever wings for completely monolithic MAVs." 15396. Mitchell, A. (2015): Collecting in collections: a PCR strategy and primer set for DNA barcoding of decades-old dried museum specimens. *Molecular Ecology Resources* 15(5): 1102-1111. (in English) ["Natural history museums are vastly underutilized as a source of material for DNA analysis because of perceptions about the limitations of DNA degradation in older specimens. Despite very few exceptions, most DNA barcoding projects, which aim to obtain

sequence data from all species, generally use specimens collected specifically for that purpose, instead of the wealth of identified material in museums, constrained by the lack of suitable PCR methods. Any techniques that extend the utility of museum specimens for DNA analysis therefore are highly valuable. This study first tested the effects of specimen age and PCR amplicon size on PCR success rates in pinned insect specimens, then developed a PCR primer set and amplification strategy allowing greatly increased utilization of older museum specimens for DNA barcoding. PCR success rates compare favourably with the few published studies utilizing similar aged specimens, and this new strategy has the advantage of being easily automated for high-throughput laboratory workflows. The strategy uses hemi-nested, degenerate, M13-tailed PCR primers to amplify two overlapping amplicons, using two PCRs per amplicon (i.e. four PCRs per DNA sample). Initial PCR products are reamplified using an internal primer and a M13 primer. Together the two PCR amplicons yield 559 bp of the COI gene from Coleoptera, Lepidoptera, Diptera, Hemiptera, Odonata and presumably also other insects. BARCODE standard-compliant data were recovered from 67% (56 of 84) of specimens up to 25 years old, and 51% (102 of 197) of specimens up to 55 years old. Given the time, cost and specialist expertise required for fieldwork and identification, 'collecting in collections' is a viable alternative allowing researchers to capitalize on the knowledge captured by curation work in decades past." 15399. Mlynarek, J.J. (2015): Testing the enemy release hypothesis in a native insect species with an expanding range. *PeerJ* 3:e1415 <https://dx.doi.org/10.7717/peerj.1415>: 12 pp. (in English) ["The enemy release hypothesis (ERH) predicts that the spread of (invasive) species will be facilitated by release from their enemies as they occupy new areas. However, the ERH is rarely tested on native (non-invasive, long established) species with expanding or shifting ranges. I tested the ERH for *Enallagma clausum* whose range has recently expanded in western Canada, with respect to its water mite and gregarine parasites. Parasitism levels (prevalence and intensity) were also compared between *E. clausum* and a closely related species, *Enallagma boreale*, which has long been established in the study region and whose range is not shifting. A total of 1,150 damselflies were collected at three 'old' sites for *E. clausum* in Saskatchewan, and three 'new' sites in Alberta. A little more than a quarter of the damselflies collected were parasitized with, on average, 18 water mite individuals, and 20% were parasitized by, on average, 10 gregarine individuals. I assessed whether the differences between levels of infection (prevalence and intensity) were due to site type or host species. The ERH was not supported: *Enallagma clausum* has higher or the same levels of parasitism in new sites than old sites. However, *E. boreale* seems to be benefitting from the recent range expansion of a native, closely related species through ecological release from its parasites because the parasites may be choosing to infest the novel, potentially naïve, host instead of the well-established host." 15400. Mlynarek, J.J.; Knee, W.; Smith, B.; Forbes, M.R. (2015): Regionally widespread parasitic water mites have relatively broad host species ranges. *Canadian Journal of Zoology* 93(10): 741-746. (in English) ["Certain parasite species have free-living stages so habitat range may influence host range. We tested whether regional occurrence and habitat use of parasitic water mites was related to their host species range. We collected 7445 *Arrenurus* mites from 7107 coenagrionid damselflies, representing 11 host species from 13 sites in southeastern Ontario and southwestern Quebec. Because larval water mite larvae are difficult to identify morphologically to species we chose to amplify the barcode fragment of cytochrome oxidase subunit 1 to explore host ranges. Fifteen Operational Taxonomic Units or clades were identified based on the amplification from 217 larval mites. The *Arrenurus* clades that were present in both bog and marsh habitats had a broader host species range than clades found only in marshes (the comparison with one clade found only in bogs lacked statistical power). As predicted, host species range increased with the regional occurrence of an *Arrenurus* clade. Additionally, the most commonly barcoded species also have high host species ranges. This result could be because species with broader host ranges are more common and were more likely to be sampled and barcoded (an explanation we favour), or due to sampling bias. Although this is the first study exploring whether habitat range affects host range, further investigation is needed to tease apart which habitat factors influence host species ranges the most." 15401. Mlynarek, J.J.; Knee, W.; Forbes, M.R. (2015): Host phenology, geographic range size and regional occurrence explain interspecific variation in damselfly–water mite associations. *Ecography* 38(7): 670-680. (in English) ["In this study, we tested which host species' characteristics explain the nature and level of parasitism for host damselfly (*Coenagrionidae*)–water mite (*Arrenuridae*) parasite associations. Prevalence and intensity of mite parasites, and mite species richness were examined in relation to geographic range size, regional occurrence, relative local abundance, phenology and body size of host damselfly species. A total of 7107 damselfly individuals were collected representing 16 species from 13 sites in southeastern Ontario and southwestern Quebec, Canada. Using comparative methods, differences in prevalence and intensity of parasitism could be predicted by a host species' geographic range and phenology. Barcoding based on Cytochrome Oxidase I revealed 15 operational taxonomic units (OTUs) for mite species. The number of mite OTUs known to infest a given host species was explained by a host species' regional occurrence. Our findings demonstrate the need to measure factors at several ecological scales in order to understand the breadth of evolutionary interactions with host–parasite associations and the selective 'milieu' for particular species of both hosts and parasites." Kelcey (ed.): *Vertebrates and Invertebrates of European Cities: Selected Non-Avian Fauna*. Springer New York: 453-494. (in English) ["Rotterdam is located on the west coast of continental Europe (51°55'51" N, 4°8'45" E). It is the second largest city in The Netherlands and occupies almost 320 km², of which a little less than 115 km² is water. Rotterdam has a maritime temperate climate with a mild winter, a mean annual precipitation of 815 mm and a mean annual temperature of 10 °C. The average wind speed is 5 m/s. The dominant soil types are sand, sea clay and peat. This chapter is based on records of invertebrates that occurred within the boundaries of Rotterdam from 1 January 1980 until now. The chapter describes the Decapoda (in particular, the crayfish and crab families), 23 species; Diptera, Stratiomyidae (soldierflies), 17 species; Diptera, Syrphidae (hoverflies), 120 species; Heteroptera 'aquatica' (bugs—aquatic families), 31 species; Hymenoptera, Apidae s.l. (bees), 94 species; Lepidoptera (butterflies and moths), 35 and 1034 species, respectively; Mollusca (terrestrial and non-marine aquatic molluscs), 68 and 49 species; Odonata (dragonflies and damselflies), a total of 36 taxa; Orthoptera (grasshoppers and crickets), a total of 24 taxa. The figures include migrants, non-native species and vagrants. The species-richness of these groups of invertebrates is discussed and related to factors such as geomorphological features, geographical position and land use." 15404. Mohammed, N.E.M. (2015): Dragonfly nymphs as active predators of Cyclops and mosquito larvae. B.Sc (Hons.) (Zoology), Medical Entomology and vector control, University of Khartoum: XII + 68 pp. (in English, with Arab summary) [Sudan; "The aim of this study is to determine, the efficiency of Odonata full-grown nymphs, represented by certain species as active predators of Cyclops, the intermediate host of *Dracunculus medinensis*. Prey-organisms also used included beside Cyclops the 1st instar Culicine and Anopheline mosquito larvae. Five laboratory experiments were carried out and several variables were investigated. e. g. predation efficiency among full-grown nymphs of *Crocothemis erythraea*, *Aeshna rileyi*) and *Ischnura segenalensis* and predation capacity of members of these families. To test this variable, 50 and then 100 specimens of *Mesocyclops aspericornis* and one full-grown nymph were used in each experiment. Experiments were repeated five times, Relative vulnerability of *Mesocyclops aspericornis* versus Anopheline or Culicine larvae (1st stage), was determined using *I. segenalensis* nymph, twenty-five organisms of each prey animal were used. Variables also included presence or absence of substrata and colour of background. To test these twenty-five *Mesocyclops aspericornis* with one full-grown nymph of *I. segenalensis* were used in each experiment. All experiments were carried out (at room temperature), experiments were conducted using small "Talis" dishes and depth of water was 5cm and surface diameter of water was 16.1cm. Numbers of prey-organisms were recorded after 24hrs. Wild Odonata nymphs and Cyclops were used. Results of predation capacity revealed that the average percent of Cyclops eaten by full-grown nymphs of *Coenagrionidae* was greater (46.4%) than *Libellulidae* (30.6%) and *Aeshnidae* (28.6%). This means that *I. segenalensis* nymph is the most voracious compared to the other two species). Results of vulnerability tests showed that the mean percent of 1st stage Culicine iv larvae consumed by *I. segenalensis* (53.97%) was greater than that of Cyclops (33.94%) and for *Anopheles* larvae consumed the percentage was (64.63%) and for Cyclops (33.66) this means that Culicine and Anopheline larvae were more vulnerable to predation than Cyclops; however Anopheline larvae were more vulnerable than Culicine ones. Similarly experiments on substrata showed that the mean percent of Cyclops eaten from water without plant substrata (42.47%) was greater than that eaten with floating plant substrata (19.68%). This means that presence of substrata did not enhance predation by *I. segenalensis*. As for colours result obtained showed that the mean percent of Cyclops which were eaten by *I. segenalensis* nymphs was greater in white colour background (63.51%) compared to other background colours: red (22.37%), blue (26.62%), green (29.61%) and black (22.01 %) and the differences between white colour and other colours were highly significant, ($P=0.01$) on the other hand no significant difference was detected among other four colours. This means that White colour of background did enhance predation." (Author)] Address: not stated

15405. Moldowan, P.D.; Keevil, M.G.; Mills, P.B.; Brooks, R.J.; Litzgus, J.D. (2015): Diet and feeding behaviour of

Snapping Turtles (*Chelydra serpentina*) and Midland Painted Turtles (*Chrysemys picta marginata*) in Algonquin Provincial Park, Ontario. *The Canadian Field-Naturalist* 129(4): 403-408. (in English) ["We compare diet and feeding behaviour of Snapping Turtles (*Chelydra serpentina*) and Midland Painted Turtles (*Chrysemys picta marginata*) in Algonquin Provincial Park, Ontario, Canada. We observed young *Chelydra* and *Chrysemys* turtles feeding on insect and amphibian larvae in ephemeral ponds, adult *Chrysemys* terrestrially foraging on odonate larvae, and adult *Chelydra* consuming aquatic vegetation and seeds. These and other observations highlight the importance of seasonally available habitat and food for juvenile turtles. We also discuss the evidence for, and importance of, turtles as seed-dispersal agents for aquatic vegetation. Illustrative video recordings accompany our dietary observations.... On 22 May 2011, an adult female *Chrysemys* was seen climbing onto Sphagnum bog mats to catch emergent dragonfly larvae that were preparing to metamorphose (Video 4, Supplementary Material: <https://www.youtube.com/watch?v=Z7LNdafj1HQ&feature=youtu.be>). The turtle appeared to search actively for terrestrial prey and to identify visually motionless dragonfly larvae. This turtle plucked dragonfly larvae from low-lying stems of bog vegetation and carried her prey back to water before feeding. Freshwater turtles have a soft, flattened eye lens that permits emmetropic (normal-sighted) vision and comparable focus in air and water ..., perhaps allowing efficient foraging in both media." (Authors)] Address: Litzgus, J.D., Dept Biology, Laurentian Univ., 935 Ramsey Lake Road, Sudbury, Ontario P3E 2C6 Canada. E-mail: jlitzgus@laurentian.ca

15406. Monroe, E.M.; Britten, H.B. (2015): Single-sample estimation of effective population size in several populations of the endangered Hine's emerald dragonfly. *Freshwater Science* 34(3): 1058-1064. (in English) ["*Somatochlora hineana* is the only odonate on the US Endangered Species list. It prefers discrete fen-and-wet-meadow habitat from Ontario, Canada, to Missouri, USA. This habitat has been destroyed across much of *S. hineana*'s range. Its conservation genetics were assessed by microsatellite analysis in a previous study. We applied 2 common single-sample estimators to the same data set to estimate effective population size (N_e), or effective number of breeders, in 5 populations (separated into adult and naiad stage classes) across the species' range in 2008 and 2010–2011. Populations of the species in the Upper Peninsula of Michigan, the Door Peninsula of Wisconsin, and along the Des Plaines River Valley in Illinois are made up of individuals collected from multiple sites, but the other 2 populations, at Cedarburg Bog, Wisconsin, and along the Lower Wisconsin River, consist of samples from single habitats disjunct from other known sites. N_e for *S. hineana* were similar to those for other endangered insects and ranged from 22 adults in the Des Plaines River Valley population in 2010 to 200 adults in the Door Peninsula population in 2010 based on approximate Bayesian estimation in ONeSAMP and from 8 naiads in the Door Peninsula population to 419 adults in the Des Plaines River Valley population based on the linkage disequilibrium

method in NeEstimator. These Ne values confirm the endangered status of this species and indicate that efforts to maintain current habitats and connectivity to suitable habitat are essential to maintaining genetic diversity." (Authors)] Address: Monroe, Emy, Whitney Genetics Lab, US Fish and Wildlife Service, 555 Lester Avenue, Onalaska, Wisconsin 54650 USA. E-mail: emy_monroe@fws.gov

15408. Mori, T.; Yanagisawa, Y.; Kitani, Y.; Sugiyama, M.; Kishida, O.; Nishimura, K. (2015): Gene expression profiles in *Rana pirica* tadpoles following exposure to a predation threat. *BMC Genomics* 2015, 16:258 doi:10.1186/s12864-015-1389-4: 17 pp. (in English) ["Background: *Rana pirica* tadpoles show morphological changes in response to a predation threat: larvae *Aeshna nigroflava* (= *A. crenata*) induce heightened tail depth, whereas larval salamander *Hynobius retardatus* induce a bulgy morphology with heightened tail depth. Although both predators induce similar tail morphologies, it is possible that there are functional differences between these tail morphs. Results; Here, we performed a discriminant microarray analysis using *Xenopus laevis* genome arrays to compare tail tissues of control and predator-exposed tadpoles. We identified 9 genes showing large-scale changes in their expression profile: ELAV-like1, methyltransferase like 7A, dolichyl-phosphate mannosyltransferase, laminin subunit beta-1, gremlin 1, BCL6 corepressor-like 1, and three genes of unknown identity. A further 80 genes showed greater than 5 fold differences in expression after exposure to dragonfly larvae and 81 genes showed altered expression after exposure to larval salamanders. Predation-threat responsive genes were identified by selecting genes that reverted to control levels of expression following removal of the predator. Thirteen genes were induced specifically by dragonfly larvae, nine others were salamander-specific, and sixteen were induced by both. Functional analyses indicated that some of the genes induced by dragonfly larvae caused an increase in laminins necessary for cell adhesion in the extracellular matrix. The higher expression of gremlin 1 and HIF1a genes after exposure to dragonfly larvae indicated an in vivo hypoxic reaction, while down-regulation of syndecan-2 may indicate impairment of angiogenesis. Exposure to larval salamanders caused down-regulation of XCIRP-1, which is known to inhibit expression of adhesion molecules; the tadpoles showed reduced expression of ca(E)-catenin, small muscle

protein, dystrophin, and myosin light chain genes. Conclusion: The connective tissue of tadpoles exposed to larval salamanders may be looser. The differences in gene expression profiles induced by the two predators suggest that there are functional differences between the altered tail tissues of the two groups of tadpoles." 15412. Murugan, K.; Dinesh, D.; Kumar, P.J.; Panneerselvam, C.; Subramaniam, J.; Madhiyazhagan, P.; Suresh, U.; Nicoletti, M.; Alarfaj, A.A.; Munusamy, M.A.; Higuruchi, A.; Mehlhorn, H.; Benelli, G. (2015): *Datura metel*-synthesized silver nanoparticles magnify predation of dragonfly nymphs against the malaria vector *Anopheles stephensi*. *Parasitology Research* 114(12): 4645-4654. (in English) ["Malaria is a life-threatening disease caused by parasites transmitted to people and animals through the bites of infected mosquitoes. The employ of synthetic insecticides to control *Anopheles* populations leads to high operational costs, non-target effects, and induced resistance. Recently, plant-borne compounds have been proposed for efficient and rapid extracellular synthesis of mosquitocidal nanoparticles. However, their impact against predators of mosquito larvae has been poorly studied. In this study, we synthesized silver nanoparticles (AgNPs) using the *Datura*

metel leaf extract as reducing and stabilizing agent. The biosynthesis of AgNPs was confirmed analyzing the excitation of surface plasmon resonance using ultraviolet–visible (UV–vis) spectroscopy. Scanning electron microscopy (SEM) showed the clustered and irregular shapes of AgNPs, with a mean size of 40–60 nm. The presence of silver was determined by energy-dispersive X-ray (EDX) spectroscopy. Fourier transform infrared (FTIR) spectroscopy analysis investigated the identity of secondary metabolites, which may be acting as AgNP capping agents. In laboratory, LC50 of *D. metel* extract against *Anopheles stephensi* ranged from 34.693 ppm (I instar larvae) to 81.500 ppm (pupae). LC50 of AgNP ranged from 2.969 ppm (I instar larvae) to 6.755 ppm (pupae). Under standard laboratory conditions, the predation efficiency of *Anax immaculifrons* nymphs after 24 h was 75.5 % (II instar larvae) and 53.5 % (III instar larvae). In AgNP-contaminated environment, predation rates were boosted to 95.5 and 78 %, respectively. Our results documented that *D. metel*-synthesized AgNP might be employed at rather low doses to reduce larval populations of malaria vectors, without detrimental effects on behavioral traits of young instars of the dragonfly *Anax immaculifrons*." 15414. Mutlu, O.; Ulak, G.; Kokturk, S.; Celikyurt, I.K.; Tanyeri, P.; Akar, F.; Erden, F. (2015): Effects of a dragonfly (*Anax i.*) homeopathic remedy on learning, memory and cell morphology in mice. *Homeopathy* 105(1): 96-101. (in English) ["Highlights: •*Anax i.* impair learning acquisition. •*Anax i.* chronically impair reference memory. •*Anax i.* improved disturbed cell morphology. Background: Homeopathy is a form of alternative medicine in which uses highly diluted preparations that are believed to cause healthy people to exhibit symptoms similar to those exhibited by patients. The aim of this study was to investigate the effects of dragonfly (*Anax imperator*, *Anax i.*) on learning and memory in naive mice using the Morris water maze (MWM) test; moreover, the effects of dragonfly on MK-801-induced cognitive dysfunction were evaluated. Methods: Male balb-c mice were treated with dragonfly (30C and 200C) or MK-801 (0.2 mg/kg) alone or concurrently (n = 10). Dragonfly (D) and MK-801 were administered subchronically for 6 days intraperitoneally 60 min and 30 min, respectively, before the daily performance of the MWM test. Results: This study revealed that in the familiarization session and first session of

the MWM test, *Anax i.* D30 significantly decreased escape latency compared to the control group, although MK-801, D30 and D200 significantly increased escape latency at the end of five acquisition sessions. *Anax i.* combined with dizocilpine maleate (MK-801) also significantly decreased escape latency in the familiarization session and first session of the MWM test, although this combination increased escape latency compared to the MK-801 alone group at the end of the test. Time spent in escape platform's quadrant in the probe trial significantly decreased while mean distance to platform significantly increased in MK-801, D30 and D200 groups. In the MWM test, *Anax i.* combined with MK-801 significantly decreased speed of the animals compared to the MK-801 alone group. General cell morphology was disturbed in the MK-801 group while D30 and D200 seemed to improve cell damage in the MK-801 group. Conclusions: These results suggest that the homeopathic *Anax i.* can impair learning acquisition and reference memory, and it has beneficial effects on disturbed cell morphology." (Authors)] Address: Mutlu, O., Dept of Pharmacology, Medical Faculty, Kocaeli Univ., 41380, Kocaeli, Turkey. E-mail: oguzmutlu80@hotmail.com

15415. Nair, G.A.; Morse, J.C.; Marshall, S.A. (2015): Aquatic insects and their societal benefits and risks. *Journal of Entomology and Zoology Studies* 3(3): 171-177. (in English) ["Information on the aquatic insects and their benefits and risks to the society are scanty among the general public, students and the scientific community, when compared with the same on the land forms. In this article, an attempt is made to overcome this deficiency. A brief description is furnished along with the representative photographs of eleven orders of aquatic insects (including Odonata). Detailed information is presented on the beneficial role of aquatic insects in food webs, biomonitoring, fishing and control of noxious weeds. The harmful impacts caused by these animals to the society and the ecosystem by way of general nuisance, transmission of diseases and destruction of crops, are described. The importance of the need for a new generation of aquatic entomologists, is stressed." 15416. Natsumeda, T.; Takamura, N.; Nakagawa, M.; Kadono, Y.; Tanaka, T.; Mitsuhashi, H. (2015): Environmental and biotic characteristics to discriminate farm ponds with and without exotic largemouth bass and bluegill in western Japan. *Limnology* 16(3): 139-148. (in English) ["We compared the environmental and biotic characteristics of farm ponds with and without the invasive fish, largemouth bass (*Micropterus salmoides*), and bluegill (*Lepomis macrochirus*), with varying degrees of aquatic vegetation cover in western Japan. Redundancy analysis (RDA) revealed that aquatic vegetation cover and pond area were significant environmental variables in explaining the variance in aquatic organisms. Aquatic vegetation cover predominantly affected Odonata and Hemiptera larvae, and the native cyprinid, *Hemigrammocypripis rasborella*, while the pond area

mainly affected the two exotic fishes (largemouth bass and bluegill), Viviparidae, Oligochaeta, Ephemeroptera, and chironomid larvae. In the RDA biplot for aquatic organisms, the RDA1 axis appeared to separate the exotic fish group (bluegill, largemouth bass, Gammaridae, Oligochaeta, Viviparidae, Ephemeroptera, Trichoptera, and chironomid larvae) from the native fish group (*H. rasborella*, *Oryzias latipes*, *Rhinogobius* sp., Odonata, shrimps, and Hemiptera larvae). The best path model results indicated that the presence of piscivorous largemouth bass had a significantly negative effect on native fish numbers; largemouth bass also had a positive indirect effect on benthic organism numbers. Our data suggest that the depletion of native fishes via top-down effects by exotic largemouth bass may indirectly increase the number of benthic organisms as a result of trophic-cascading effects." (Authors)] Address: Natsumeda, T., Global Environmental Forum, Tsukuba, Ibaraki, 305-8506, Japan. E-mail: natsumed@mx.ibaraki.ac.jp

15417. Nel, A.; Huang, D. (2015): A new genus and species of damsel-dragonfly (Odonata: Stenophlebiidae) from the Lower Cretaceous of Inner Mongolia, China. *Cretaceous Research* 56: 421-425. (in English) ["A taxon of the Stenophlebiidae, *Yixianstenophlebia magnifica* gen. et sp. nov., is described from the Lower Cretaceous Yixian Formation at Liutiaogou, Ningcheng County, Inner Mongolia of China. Its closest relative is the Late Jurassic European genus *Stenophlebia*. This new discovery is helpful to understand the Jehol Biota assemblage at Liutiaogou Locality. It also confirms that the Stenophlebiidae was a very diverse and widespread family during the Early Cretaceous. The causes of its extinction in the Late Cretaceous remain enigmatic." 15420. Newell Wohner, P.J.; Cooper, R.J.; Greenberg, R.S.; Schweitzer, S.H. (2015): Weather affects diet composition of rusty blackbirds wintering in suburban landscapes. *The Journal of Wildlife Management* 80(1): 91-100. (in English) ["The rusty blackbird (*Euphagus carolinus*) is a species of conservation concern throughout its range and the cause of the species' population decline is unknown. We studied diet composition of rusty blackbirds with stable isotope mixing models in suburban landscapes in the southeastern United States. We captured blackbirds in Georgia and South Carolina from 2009 to 2012, and estimated proportions of earthworm, other animals, pecan, and acorn incorporated into individual diets. On the Piedmont Plateau, terrestrial and aquatic earthworms constituted the largest proportion incorporated into the diet ($39\% \pm 2.9$; mean \pm SD by site and year) and animals other than earthworms (mostly larval invertebrates Odonata and Diptera) constituted $27\% \pm 12.9$. In contrast, on the Coastal Plain, which featured milder winters than the Piedmont, earthworms constituted a lower proportion ($19\% \pm 1.2$) of incorporated food items and animals other than earthworms comprised $62\% \pm 3.3\%$ of the diet. Increased incorporation of earthworms in the diet was related to increased upcoming precipitation and daily maximum temperature. Rusty blackbirds incorporated more tree mast into their diet on the Piedmont Plateau than the Coastal Plain. Increased incorporation of tree mast was related to advancing cold temperature. Mast, including crushed pecans (*Carya illinoensis*) and pre-opened small-seeded red oak (*Quercus* spp.) acorns, is a high-lipid dietary component of blackbirds wintering in colder climates, and is incorporated prior to extreme cold weather. Therefore, planting mast trees, especially lipid-rich pecan, could be used to augment resources in known rusty blackbird wintering hotspots. Maintaining shallowly flooded wetlands with a fluctuating water regime and residential lawns with abundant red oak (*Quercus* spp.) leaf litter would promote acorn and invertebrate resources including earthworms." 15421. Nicholson, D.B.; Mayhew, P.J.; Ross, A.J. (2015): Changes to the fossil record of insects through fifteen years of discovery. *PLoS ONE* 10(7): e0128554. doi:10.1371/journal.pone.0128554: 61 pp. (in English) ["The first and last occurrences of hexapod families (including Odonata) in the fossil record are compiled from publications up to end-2009. The major features of these data are compared with those of previous datasets (1993 and 1994). About a third of families (>400) are new to the fossil record since 1994, over half of the earlier, existing families have experienced changes in their known stratigraphic range and only about ten percent have unchanged ranges. Despite these significant additions to knowledge, the broad pattern of described richness through time remains similar, with described richness increasing steadily through geological history and a shift in dominant taxa, from Palaeoptera and Polyneoptera to Para-neoptera and Holometabola, after the Palaeozoic. However, after detrending, described richness is not well correlated with the earlier datasets, indicating significant changes in shorter-term patterns. There is reduced Palaeozoic richness, peaking at a different time, and a less pronounced Permian decline. A pronounced Triassic peak and decline is shown, and the plateau from the mid Early Cretaceous to the end of the period remains, albeit at substantially higher richness compared to earlier datasets. Origination and extinction rates are broadly similar to before, with a broad decline in both through time but episodic peaks, including end-Permian turnover. Origination more consistently exceeds extinction compared to previous datasets and exceptions are mainly in the Palaeozoic. These changes suggest that some inferences about causal mechanisms in insect macroevolution are likely to differ as well." (Authors)] Address: Nicholson, D.B., Department of Biology, University of York, York, UK. E-mail: david.nicholson@nhm.ac.uk

15422. Nilsson-Örtman, V.; Rogell, B.; Stoks, R.; Johansson, F. (2015): Ontogenetic changes in genetic variances of age-dependent plasticity along a latitudinal gradient. *Heredity* 115(4): 366-378. (in English) ["The expression of phenotypic plasticity may differ among life stages of the same organism. Age-dependent plasticity can be important for adaptation to heterogeneous environments, but this has only recently been recognized. Whether age-dependent plasticity is a common outcome of local adaptation and whether populations harbour genetic variation in this respect remains largely unknown. To answer these questions, we estimated levels of additive genetic variation in age-dependent plasticity in six species of damselflies sampled from 18 populations along a latitudinal gradient spanning 3600km. We reared full sib larvae at three temperatures and estimated genetic variances in the height and slope of thermal reaction norms of body size at three points in time during ontogeny using random regression. Our data show that most populations harbour genetic variation in growth rate (reaction norm height) in all ontogenetic stages, but only some populations and ontogenetic stages were found to harbour genetic variation in thermal plasticity (reaction norm slope). Genetic variances in reaction norm height differed among species, while genetic variances in reaction norm

slope differed among populations. The slope of the ontogenetic trend in genetic variances of both reaction norm height and slope increased with latitude. We propose that differences in genetic variances reflect temporal and spatial variation in the strength and direction of natural selection on growth trajectories and age-dependent plasticity. Selection on age-dependent plasticity may depend on the interaction between temperature seasonality and time constraints associated with variation in life history traits such as generation length." 15423. Novelo-Gutiérrez, R.; Gómez-Anaya, J.A.; Smith-Gómez, S.A. (2015): Description of the larva of *Epigomphus crepidus* Kennedy, 1936 (Odonata: Gomphidae). *Zootaxa* 4027(4): 587-592. (in English, with Spanish summary) ["The larva of *E. crepidus* is described and figured and compared with other described congeners. It is characterized by 3rd antennomere spindle-shaped, flattened dorso-ventrally, twice longer than its widest part; ventral pad of hypopharynx pentagonal; prementum subrectangular, with lateral margins slightly convex on apical 0.60; ligula very poorly developed, with a ventral row of nine short, truncate teeth on middle, and dorsal rows of short, stout piliform setae. Abdomen lacking dorsal protuberances, lateral spines on S7-9 divergent; sternites 3-8 divided into five plates, sternites 2 and 9 divided into three plates; male epiproct with a pair of dorsal tubercles rounded apically and divergent at basal 0.30. It differs from other species mainly in 3rd antennomere, sides of prementum and serrations on lateral margins of S7-9." 15426. Nowak, A. (2015): Application of Voronoi diagrams in contemporary architecture and town planning. *Challenges of Modern Technology* 6(2): 30-34. (in English) ["Modern design methods rely increasingly on understanding the nature of processes and principles of self-organization of biological structures and their representation using mathematical models that may apply in technology, including architecture. As a result, bionic design elements play a more meaningful role in shaping contemporary architecture and urban planning. The development of computer technology has made it possible to create more complex and complicated structures and surfaces inspired by natural forms. The inspiration for the discretization of the surface, using the Voronoi diagram, as seen in the honeycomb structure or the dragonfly wing, is increasingly applied in shaping the elevation of contemporary buildings. As a mathematical problem, the division of space fascinates scientists as well as architects. Consequently, architects use the spatial Voronoi cells also in shaping the structural forms. Today Voronoi diagrams are an important source of inspiration for architects and urban planners as a surface discretization method and a way of creating structural elements or spatial forms and as flooring patterns in urban projects. The use of mathematical models represent the structure and organization of the forms found in nature, which is increasingly used in the multidisciplinary architectural design. The design of the structures and elements both in architecture and urban planning using methods of computational geometry makes new opportunities for architectural and urban projects as seen by the Voronoi tessellation." 15427. Nowlin, K.; Boseman, A.; Covell, A.; LaJeunesse, D. (2015): Adhesion-dependent rupturing of *Saccharomyces cerevisiae* on biological antimicrobial nanostructured surfaces. *Journal of The Royal Society Interface* 12(102): 12 pp. (in English) ["Recent studies have shown that some nanostructured surfaces (NSS), many of which are derived from surfaces found on insect cuticles, rupture and kill adhered prokaryotic microbes. Most important, the nanoscale topography is directly responsible for this effect. Although parameters such as cell adhesion and cell wall rigidity have been suggested to play significant roles in this process, there is little experimental evidence regarding the underlying mechanisms involving NSS-induced microbial rupture. In this work, we report the NSS-induced rupturing of a eukaryotic microorganism, *Saccharomyces cerevisiae*. We

show that the amount of NSS-induced rupture of *S. cerevisiae* is dependent on both the adhesive qualities of the yeast cell and the nanostructure geometry of the NSS. Thus, we are providing the first empirical evidence that these parameters play a direct role in the rupturing of microbes on NSS. Our observations of this phenomenon with *S. cerevisiae*, particularly the morphological changes, are strikingly similar to that reported for bacteria despite the differences in the yeast cell wall structure. Consequently, NSS provide a novel approach for the control of microbial growth and development of broad-spectrum microbicidal surfaces. ... The wings of ... *Progomphus obscurus* were all collected from Greensboro, NC, USA." 15428. Okoro, O.J. (2015): Ecology of aquatic insects in Opi lake, Enugu state, Nigeria. M.Sc. Thesis, Department of Zoology and Environmental Biology, Faculty of Biological Sciences, University of Nigeria Nsukka: 110 pp. (in English) ["The ecology of aquatic insects of Opi Lake was carried out to determine their composition, abundance and diversity from February to July, 2014. Adult insects of different species were collected from the water surface using a dip-net with Nytex® netting of 500µm mesh. In addition, adult Insects and nymphs were collected from the vegetation around the lake using a sweep net with mesh size of 250µm, while bottom dwellers were sampled using a scoop net. The lake was divided into three sampling stations as a result of the nature and amount of the vegetation, and the type of substratum found in each location. Station 1 had vegetation, shade and detritus, Station 2 had no shade, very little detritus and vegetation, while Station 3 had shade, detritus with no vegetation. The physico-chemical parameters and heavy metals concentrations of the lake were determined while the climatic data of the area was collected from the Center for Space Science University of Nigeria Nsukka. A total number of 1,042 insects representing 30 species, belonging to 26 families and 8 orders were recorded. Odonata had the highest mean abundance (44.52%) in all the stations, followed by Hemiptera (23.32%) which was the most diverse group. Hemiptera had the highest number of families (8 out of the 26 families collected). Other insect orders collected with their abundance include: Coleoptera (12.28%), Orthoptera (10.29%), Hymenoptera (5.09%), Diptera (3.36%), Trichoptera (1.06%) and Lepidoptera (0.01%). Station 1 recorded the maximum number (46.35%) of aquatic insects throughout the sampling season. However, stations 2 and 3 recorded 28.98% and 24.66% of aquatic insects respectively. The abundance of insects was maximum in the month of July (20.44%) and minimum in April (8.16%). The abundance and distribution of insect species varied and were not constant from one month to another during the period of study, due to biotic and abiotic factors. There was high species diversity of aquatic insects in the different strata of the lake, indicating

the rich and diverse group of insects in the study area. Dissolved Oxygen had an inverse relationship with Orthoptera ($r = -0.63$, $p < 0.01$) and Hymenoptera ($r = -0.54$, $p < 0.05$). Diptera also had negative relationship with depth ($r = -0.48$, $p < 0.05$). There was positive correlation between Hemiptera and Copper ($r = 0.78$, $p < 0.01$), while Iron also correlated positively with Coleoptera ($r = 0.47$, $p < 0.05$) and Lepidoptera ($r = 0.59$, $p < 0.05$). Among the insects and zooplankton, Odonata had positive correlations with Rotifera ($r = 0.502$, $p < 0.05$), Cyclops ($r = 0.541$, $p < 0.05$), Bosmina ($r = 0.53$, $p < 0.05$) and Daphnia ($r = 0.595$, $p < 0.01$). Orthoptera also showed positive relationship with Fish egg ($r = 0.684$, $p < 0.01$). Also, with phytoplankton, Odonata had positive relationship with Chlorophyceae ($r = 0.505$, $p < 0.05$) and Xanthophyceae ($r = 0.499$, $p < 0.05$). Orthoptera correlated positively with Cryptophyceae ($r = 0.491$, $p < 0.05$) and Xanthophyceae ($r = 0.487$, $p < 0.05$). This therefore, adds to the fact that undisturbed habitat quality is more suitable for insects to breed and multiply under the natural ecosystem with abundant food supply." 15429. Okuyama, H.; Samejima, Y.; Tsubaki, Y. (2015): Smaller damselflies have better flight performance at lower body temperature: implications for microhabitat segregation of sympatric *Mnais* damselflies. *International Journal of Odonatology* 18(3): 217-224. (in English) ["In many cases where two closely related species coexist, ecological interaction or reproductive interference drive species to diversify in their body size and/or other signal traits, often concurrently with microhabitat segregation. However, it is usually unclear how character diversification is associated with microhabitat segregation. We performed laboratory experiments using males of two damselfly species (*Mnais costalis* and *Mnais pruinosa*) collected from a syntopic site in Shiga Prefecture, Japan. We analyzed the effects of body temperature and body size on three indices of flight performance: wing-beat frequency and flight speed as measures of thrust production, and minimum body temperature for flight (MBTF). The results showed that the MBTF was correlated with body size: the smaller species (*M. pruinosa*) flew better than the larger species (*M. costalis*) in a cool environment. The initial flight speed was positively correlated with body temperature, but negatively correlated with body size. The wing-beat frequency was also positively correlated with body temperature, but negatively correlated with body size. The combined effects of body size and body temperature on wing-beat frequency meant that overall, there was no significant difference in initial flight speed. We suggest that the effect that body size and temperature have on flight performance explains the previously documented microhabitat segregation occurring between these two species, with the larger *M. costalis* preferring sunny environments and *M. pruinosa* preferring shady environments."] Address: Okuyama, H., Center for Ecological Research, Kyoto Univ., Hirano, Otsu, Shiga, Japan. 15430. Oliveira-Junior, J.M.B.; Shimano, Y.; Gardner, T.A., Hughes, R.M.; de Marco Júnior, P.; Juen, L. (2015): Neotropical dragonflies (Insecta: Odonata) as indicators of ecological

condition of small streams in the eastern Amazon. *Austral Ecology* 40(6): 733-744. (in English) ["Sensitive and cost-effective indicators of aquatic ecosystem condition in Amazon streams are necessary to assess the effects of anthropogenic disturbances on those systems in a viable and ecologically meaningful manner. We conducted the present study in the municipality of Paragominas, state of Pará, northern Brazil, where we sampled adult dragonflies in 50 100-m-long wadeable stream sites in 2011. We collected 1769 specimens represented by 11 families, 41 genera and 97 species. The suborder Zygoptera contributed 961 individuals and Anisoptera 808. Among the 97 recorded species, nine were classified as useful indicators of ecological condition, with four species being associated with more degraded streams (three Anisoptera, one Zygoptera) and five with more preserved streams (all were Zygoptera). Anisoptera tend to provide more useful indicators of more degraded environments because they have more efficient homeostatic mechanisms and are more mobile, enabling them to tolerate a wider range of environmental conditions. By contrast, Zygoptera tend to provide a more useful role as indicators of more preserved environments and high levels of environmental heterogeneity because of their smaller body sizes and home ranges and greater ecophysiological restrictions. We conclude from our assessment of this low-order Amazonian stream system that (i) the occurrence of specific odonate species is strongly associated with the configuration of riparian vegetation, (ii) agricultural activities appear to be the main factor determining changes in the composition of odonate assemblages and (iii) these insects can act as useful indicators of the ecological consequences of riparian habitat loss and disturbance. Because generalist species invade moderately degraded areas, those areas may have high species richness but host few species of Zygoptera. Therefore, preserving dense riparian vegetation is necessary to maintain aquatic ecological condition, and that condition can be rehabilitated by planting new trees. Both require enforcing existing environmental regulations, various types of incentives and educating local communities." 15432. Orr, A.G.; Günther, A. (2015): Reported ovo-viviparity in *Heliocypha perforata* (Odonata: Chlorocyphidae) – re-assessment of the evidence, based partly on examination of the female reproductive system and mature eggs. *International Journal of Odonatology* 18(2): 169-174. (in English) ["*Heliocypha perforata* (sensu lato) is a common stream-dwelling damselfly widespread in mainland tropical Asia. Recently a report has been published suggesting possible ovo-viviparity in this species, based on the interpretation of evidence from a short video sequence. This video is re-evaluated. The internal and external anatomy of the *H. perforata* female reproductive system, including mature eggs, is examined and illustrated, to the extent that this information casts light on the observations. Three competing hypotheses are considered: (1) a prolarva or larva was expressed from the female's oviduct, due to abnormal retention of the fertilized egg in the oviduct for several days; (2) an egg, deep in the oviposition substrate, previously laid and near hatching, was disturbed by the female's probing ovipositor and the prolarva hatched, becoming briefly caught in the valves of the ovipositor; and (3) a small unidentified aquatic insect, probably of a different species and different order, was disturbed and similarly briefly caught in the valves. Based on the size and colour of the object relative to that of a mature egg and the likelihood of the event, hypothesis 3 is favoured." (Authors)] Address: Orr, A.G., Cooperative Research Centre for Tropical Rainforest Ecology and Management, Environmental Sciences, Griffith University, Nathan, Q 4111, Australia. E-mail: agorr@universal.net.au

15433. Orr, A.G.; Dow, R.A. (2015): Description of two final stadium platystictid larvae from Borneo, including that of *Drepanosticta ?attala* Lieftinck, identified using DNA barcoding (Odonata: Zygoptera: Platystictidae). *Zootaxa* 3985(4): 565-574. (in English) ["The final stadium larva of *Drepanosticta ?attala*, is described and illustrated based on a single male specimen collected at Kuala Belalong Field Studies Centre, Brunei. The larva was identified by matching the mitochondrial marker COI with that of known adult specimens. The larva presented a good match with both *D. attala* and *D. barbatula* Lieftinck in this gene, but as adults of only the former species had been collected at the locality, it is presumed more likely to be that species. Another, unidentified platystictid larva, Platystictidae A, collected at the same general locality is also described. The two larvae show significant differences from each other and from *D. sundana* Krüger, the only other Oriental region member of the family for which larval morphology is known. The three species are also compared with the larvae of the Neotropical genus *Palaemnema*, which they closely resemble, despite being currently placed in different subfamilies. Based on this known material, Oriental and Neotropical forms differ

significantly in details of mandibular morphology, especially the armature of the molar field." (Authors)] Address: Orr, A.G., Environmental Futures Research Institute, Griffith Univ. Nathan, Queensland 4111, Australia. E-mail: agorr@universal.net.au

15434. Ortega-Salas, H.; Gonzalez-Soriano, E. (2015): A new species of *Libellula* Linnaeus, 1758, from the Cuatro Ciénegas basin, Coahuila, México (Anisoptera: Libellulidae). *Zootaxa* 4028(4): 589-594. (in English, with Spanish summary) ["A new species of *Libellula* is described from specimens collected in the most interesting area of Cuatro Ciénegas, Coahuila, México. *Libellula coahuiltecana* sp. nov. is similar in colour and morphology to *L. needhami* Westfall with which it co-occurs locally. It differs from the latter by having conspicuous orange spots on base of wings and nodal area, and costal, subcostal, and wing tip areas slightly infumated with the same colour. Other differences exist in the morphology of the secondary genitalia of males and the shape of the vulvar plate of female." (Authors)] Address: Gonzalez-Soriano, E., Depto Zoología, Inst. Biol., Universidad Autónoma, Apartado Postal 70-153, 04510 Mexico, D.F., Mexico. E-mail: esoriano@mail.ibiologia.unam.mx

15435. Ortiz-Sandoval, J.J.; Konrad Górski, K.; Alonso González-Díaz, A.; Evelyn Habit, E. (2015): Trophic scaling of *Percichthys trucha* (Percichthyidae) in monospecific and multispecific lakes in western Patagonia. *Limnologia - Ecology and Management of Inland Waters* 53: 50-59. (in English) ["*Percichthys trucha* (Cuvier and Valenciennes, 1833) is a freshwater fish, endemic to southern South America and widely distributed in both, eastern and western sides of the Andes. *Percichthys trucha* has been described as top native predator in lacustrine ecosystems, experimenting diet shifting during their life history development. Salmonid invasions have impacted their natural ecology through trophic niche interference and predation over alternative high quality prey. This study focuses on populations of *P. trucha* in western Patagonia, where its trophic ecology have been less understood. We hypothesised a diet shift between juveniles and adults from lower-trophic position prey toward higher-trophic position prey. Fish were collected from 7 lakes belonging to Puelo and Baker river basins, covering a high diversity of environmental conditions. Stomach content and $\delta^{15}N$ stable isotope ratio of muscle tissues of 313 individuals were analysed. Results indicate significant differences in diet between juveniles and adults, shifting from planktonic/benthic preys towards benthic/piscivory, and concomitantly enrichment in heavier nitrogen isotope suggest trophic scaling. No trophic scaling was observed in populations inhabiting lakes with any other fish species present, essentially due to lack of *Galaxias* sp. as available prey and absence of cannibalism. Despite the fact that *P. trucha* and *Galaxias* sp. co-occur in studied river basins, no salmonid-free lakes harbouring this two native species were found, making it difficult to elucidate exact effects of salmonids on trophic scaling of *P. trucha*. Consumption of aquatic Odonata nymphs, however, arises as one of potential key mechanism for resilience of native food webs to

salmonid invasion." (Authors)] Address: Habit, Evelyn, Facultad de Ciencias Ambientales y Centro EULA, Universidad de Concepción, Concepción, Chile. E-mail: ehabit@udec.cl

15436. Osozawa, S.; Wakabayashi, J. (2015): Killer typhoons began to impact the Japanese Islands from ca. 1.55 Ma, based on phylogeography of *Chlorogomphus* (Gliding Dragonfly). *J. Earth Sci. Climat. Change* 2015, S3 <http://dx.doi.org/10.4172/2157-7617.S3-003>: 5 pp. (in English) ["*Chlorogomphus* is characterized by swarming behaviour, and strong gliding and flying. Therefore this dragonfly is expected to be easily carried by typhoon winds. This dragonfly immigrated and colonized the Pacific coast of southern Japan main islands from the Ryukyu islands. In this study, we demonstrate that the Japan mainland population is phylogenetically common to the northern Ryukyu population, but distinct from the southern Ryukyu and Taiwan populations. The East China Sea was formed between the Ryukyu island arc and Asian mainland by the rifting of the Okinawa trough that started at 1.55 Ma. Prior to this time typhoons lost strength when heading overland over the Ryukyu continental arc and continental China, but since then have maintained their strength northward because they were over water (the newly opened Okinawa trough). *Chlorogomphus* is interpreted to have speciated on each island, but it also migrated northward as a result of typhoons that carried it further than it could normally fly. The present paper shows that such typhoons that now ravage Japan may have been generated since 1.55 Ma and will continue to be dangerous, because the opening of the Okinawa trough is an ongoing process. This phenomenon is unrelated to global warming." (Authors)] Address: Osozawa, S., Department of Earth Sciences, Graduate School of Science, Tohoku University, Sendai 980-8578, Japan. E-mail: osozawa@m.tohoku.ac.jp

15437. Ott, J.; Conze, K.-J.; Günther, A.; Lohr, M.; Mauersberger, R.; Roland, H.-J.; Suhling, F. (2015): Rote Liste und Gesamtartenliste der Libellen Deutschlands mit Analyse der Verantwortlichkeit, dritte Fassung, Stand Anfang 2012 (Odonata). *Libellula Supplement* 14: 395-422. (in German, with English summary) ["Red List and checklist of Odonata of Germany, with analysis of the responsibility, version 3, early 2012 – We updated the Red List of Odonata of Germany by applying the criteria developed by the German Federal Agency for Nature Conservation, which deviate from those suggested in the IUCN Red List guidelines. The following criteria were used to assess the species: current state (in the case of dragonflies grid frequencies since 1995 are used), long-term population trend (a guess of population trends since ca 1840), short-term trend (changes in the grid frequencies 1995-2009) and existence of potential risk factors. In Germany so far 81 species of Odonata were recorded in the wild of which 79 species are considered to be established. These have been assessed against the Red List criteria. 30 species were classified into one of the Red List categories and five species into the category "near threatened". *Onychogomphus uncatatus* and *Coenagrion hyalas* are considered as "extinct" in Germany. Since 1998,

when the last Red List was published, *Boyeria irene* was newly found for Germany. Furthermore, the national responsibility for the conservation of odonate species was assessed based on the share Germany has of the total population size of the species. According to this, Germany is responsible to a great extent for conservation of *Cordulegaster bidentata* and *Aeshna cyanea*. There is also a notable responsibility for isolated outposts of *Sympecma paedisca*, *Nehalennia speciosa*, *Coenagrion armatum*, *C. ornatum*, *Aeshna caerulea*, and *Somatochlora alpestris*." (Authors)] Address: Ott, J., L.U.P.O. GmbH, Friedhofstraße 28, 67705 Trippstadt, Germany. E-mail: ott@lupogmbh.de

15438. Outomuro, D.; Johansson, F. (2015): Bird predation selects for wing shape and coloration in a damselfly. *Journal of Evolutionary Biology* 28(4): 791-799. (in English) ["Wing shape is related to flight performance, which is expected to be under selection for improving flight behaviours such as predator avoidance. Moreover, wing conspicuousness, usually involved in sexual selection processes, is also relevant in terms of predation risk. In this study, we examined how predation by a passerine bird, the white wagtail *Motacilla alba*, selects wing shape and wing colour patch size in males of the banded demoiselle *Calopteryx splendens*. The wing colour patch is intra- and intersexually selected in the study species. In a field study, we compared wings of live damselflies to wings of predated damselflies which are always discarded after predation. Based on aerodynamic theory and a previous study on wing shape of territorial tactics in damselflies, we predicted an overall short and broad wing, with a concave front margin shape to be selected by predation. This shape would be expected to improve escaping ability. Moreover, we predicted that wing patch size should be negatively selected by predation. We found that selection operated differently on fore- and hindwings. In contrast to our predictions, predation favoured a slender general forewing shape. However, the predicted wing shape was favoured in hindwings. We also found selection favouring a narrower wing colour patch. Our results suggest different roles of fore- and hindwings in flight, as previously suggested for *Calopteryx* damselflies and shown for butterflies and moths. Forewings would be more involved in sustained flight and hindwings in flight manoeuvrability. Our results differ somehow from a recently published work in the same study system, but using another population, suggesting that selection can fluctuate across space, despite the simplicity of this predator-prey system." (Authors)] Address: Outomuro, D., Dept of Ecology and Genetics, Evolutionary Biology Centre, Uppsala University, Norbyvägen 18D, Uppsala, Sweden. E-mail: outomuro.david@gmail.com

15439. Palacino Rodríguez, F.; Sarmiento, C.E.; González-Soriano, E. (2015): Morphological variability and evaluation of taxonomic characters in the genus *Erythemis* Hagen, 1861 (Odonata: Libellulidae: Sympetrinae). *Insecta Mundi* 428: 1-68. (in English) ["*Erythemis* is a Neotropical genus with ten species in which morphological characters vary widely. The aim of this paper is to study the taxonomic diversity of the genus *Erythemis* and to test the diagnostic value of morphological characters used to discriminate species. The diagnostic value

of the morphometric characters is tested using discriminant function analysis, principal component analysis, and graphical exploration of the data. A total of 134 characters were studied; of those, 53 are recoded and 81 are proposed in this work. Discrete characters such as colour, genitalia, ventral teeth of male cercus, extension of dark basal area in hind wing, and morphometric characters of abdominal carinae and antenodal wing venation are the most useful for species determination. In contrast, abdomen length/HW length ratio, vulvar lamina length, and spines of femoral structure are highly variable. A lectotype is designated for *Diplax credula* Hagen, 1861. Taxonomic keys for males and females are included, and variation in several characters is presented." (Authors)] Address: Fredy Palacino Rodríguez, F., Lab. de Sistemática y Biología Comparada de Insectos, Lab. de Artrópodos del Centro Internacional de Física, Univ. Nacional de Colombia, Grupo de Investigación en Biología (GRIB), Grupo de Investigación de Odonatos de Colombia (GINOCO), Universidad El Bosque, Bogotá, Colombia

15440. Patten, M.A.; Bried, J.T.; Smith-Patten, B.D. (2015): Survey data matter: predicted niche of adult vs breeding Odonata. *Freshwater Science* 34(3): 1114-1122. (in English) ["Assessing and categorizing habitat needs or population trends of organisms with complex life histories, such as Odonata, is challenging. All Odonata have aquatic nymphs and terrestrial adults. As a consequence, their use as indicators of ecosystem health or as umbrella species in conservation plans may be misleading if data from a particular life stage does not reflect actual residency at a freshwater site. We explored this question with an extensive data set for Odonata from Oklahoma, USA, to determine if ecological niches modelled from records of adults (i.e., lacking any evidence of breeding) differed from niches modelled for records indicating breeding (tandem pairs, ovipositing females, larvae, teneral [recently emerged adults], or exuviae [shed exoskeletons of larvae]) at surveyed sites. We predicted that models would be comparable if adult presence strongly indicates local breeding but would be dissimilar if adults occupy many more sites than those at which the species breeds. Our results supported the latter prediction. Adult models were broader geographically and had a wider, more equitable (higher evenness) balance of contributing environmental variables (niche dimensions) than did models for breeders, which tended to be more ecologically specialized. These findings suggest that surveys of adult Odonata, which are relatively easy to obtain because of organized efforts to encourage observations by citizen scientists, can paint a misleadingly broad picture of a species' ecological niche. We recommend that evidence of breeding, especially presence of teneral or exuviae, be used to outline ecological requirements when questions of conservation or population monitoring arise." 15441. Pauley, L.R.; Earl, J.; Semlitsch, R.D. (2015): Ecological effects and human use of commercial mosquito insecticides in aquatic communities. *Journal of Herpetology* 49(1):

28-35. (in English) ["In the case of contaminants that are commercially available and introduced by humans, understanding where and how often a product is used is critical in assessing its ecological impact. By contextualizing a product's ecotoxicological impact with details regarding its application, we can provide a more complete characterization of the product's environmental risk than is possible with ecotoxicological data alone. We conducted an ecotoxicology experiment to examine the interaction between predator-induced stress and one of three common mosquito insecticide formulations (Mosquito Dunks, Mosquito Bits, and Mosquito Torpedoes) on the performance of Gray Treefrog (*Hyla versicolor*) tadpoles and changes in aquatic communities in pond mesocosms. Then, to describe the extent to which each product was applied in the region surrounding our study area, we conducted a survey of mosquito insecticide practices by individuals who owned or managed property within U.S. Environmental Protection Agency region seven. When applied in the presence of predators, Mosquito Torpedo use resulted in the lowest tadpole survival rates. Mosquito Dunks also reduced tadpole survival when applied in the context of predators ($P = 0.06$), and Mosquito Bits had no effect on tadpole survival. Of land managers who applied a mosquito insecticide, 5% used Mosquito Bits, 5% used Mosquito Torpedoes, and 81% used Mosquito Dunks. Despite the fact that Mosquito Torpedoes appear to have more severe negative effects on tadpole survival than do Mosquito Dunks, the widespread use of Mosquito Dunks by individuals in our survey leads us to recommend that future research efforts be directed toward Mosquito Dunks. ... We used a factorial combination of a predatory insect treatment (with or without dragonfly larvae) crossed with an insecticide treatment (no insecticide, Mosquito Dunks, Mosquito Bits, and Mosquito Torpedoes; see below complete description of insecticide products), with three replications. For the dragonfly predator treatment, one *Anax junius* (green damer) and six *Pachydiplax longipennis* (blue dasher) late-instar larvae were added to each mesocosm on 22 May 2010. These predator densities reflect natural densities in central Missouri (JEE and RDS, unpubl. data)." 15442. Perello, M.M.; Simon, T.P.; Thompson, H.A.; Kane, D.D. (2015): Feeding ecology of the invasive round goby, *Neogobius melamostomus* (Pallas, 1814), based on laboratory size preference and field diet in different habitats in the western basin of Lake Erie. *Aquatic Invasions* 10(4): 463-474. (in English) ["The round goby, *Neogobius melanostomus*, is an invasive benthic fish species in the Laurentian Great Lakes that is threatening native fish populations through competition, predation, and trophic dynamic change. This study examined the trophic dynamic plasticity of round goby along a depth gradient based on laboratory and field observations to determine prey species consumed and mussel prey size selection. Prey size selection in the laboratory was assessed by presenting individual round goby with quagga mussels (*Dreissena rostriformis bugensis*) of various class sizes (i.e., 6.0-9.9 mm, 10.0-12.9 mm,

13.0-15.9 mm and 16.0-18.9 mm in length). Round goby exhibited a selection preference for small sized quagga mussels, although in individual trial events, mussels were consumed from all four size classes. Prey species consumed from shallow and deep sites in the western basin of Lake Erie were assessed using individual gut contents to calculate measures of prey importance, diversity, and dominance. Based on the Index of Relative Importance (IRI), Cladocera was found to be the most consumed prey item for both males and females and between study sites. Both sexes consumed a variety of prey items although females exhibited greater prey dominance or reliance on one prey item. Round goby individuals at the shallow, natural shoreline site had the highest trophic diversity, while individuals at the deep site exhibited the highest prey dominance. Diet of round goby in the western basin of Lake Erie are mainly dominated by just a few prey items." (Authors) Odonata play a minor role as diet of the round goby.] Address: Perello, Melanie, FT. 15443. Pfitzner, W.P.; Beck, M.; Weitzel, T.; Becker, N. (2015): The role of mosquitoes in the diet of adult dragon- and damselflies (Odonata). *Journal of the American Mosquito Control Association* 31(2): 187-189. (in English) ["The flood plains of the Upper Rhine Valley provide excellent conditions for the proliferation of mosquitoes as well as for the development of dragon and damselflies. It could be assumed that mosquitoes belong to the diet of the Odonata and that the latter could be harmed by the reduction of the mosquito population with the purpose of diminishing the massive nuisance for the people living there. A total of 41 adult Odonata were examined by immunoblot for remnants of mosquitoes in their guts. A rabbit antiserum against *Aedes vexans* proteins was used for the immunoblot. Only 3 *Aeshna cyanea* and 1 *Platycnemis pennipes* could be shown to have fed on mosquitoes. In specimens of the genus *Sympetrum* no mosquitoes were detected. It seems very doubtful that mosquitoes are an essential part of the Odonata diet." (Authors)] Address: German Mosquito Control Association (KABS), Georg-Peter-Suess-Str. 3, 67346 Speyer, Germany.

15444. Piché, C.; Hutchinson, R. (2015): Les libellules (Odonata) de Gatineau, Québec, d'hier à aujourd'hui. *Le Naturaliste canadien* 140(1): 12-25. (in French, with English summary) ["Gatineau is the fourth largest city in Québec (Canada). It is situated in the southwestern part of the province, on the northern bank of the Ottawa River. At least 87 species of dragonfly have been recorded in Gatineau, and surveys conducted in the city in 2012 and 2013 documented the frequency, relative abundance and breeding of 82 of these. A comparison with historical data for the period from 1886 to 1935, showed that at least 90 % of the species recorded have maintained their presence in the city since the beginning of the 20th century. However, 8 species associated with streams, rivers or temporary wetlands, may have declined or disappeared. By contrast, at least 7 generalist species associated with still water bodies, are expanding in Gatineau. With the exception of one species

from the family Coenagrionidae, these are all from the family Libellulidae. These changes in the dragonfly community are likely due to urban sprawl. Dragonflies, which are useful bio-indicators of environmental changes occurring in wetlands, can be easily observed and monitored through citizen science projects." (2015): Relative impacts of morphological alteration to shorelines and eutrophication on littoral macroinvertebrates in Mediterranean lakes. *Freshwater Science* 34(2): 410-422. (in English) ["Development of effective methods for assessing the ecological status of lakes based on littoral benthic fauna has been hampered by the lack of quantitative data on the relative impacts of key pressures on the benthic community. We used variance partitioning at 126 sites belonging to 14 natural Mediterranean lakes to analyze the pure and shared effects of eutrophication, morphological alterations, microhabitat type, lake morphometry and geographic position on the littoral macroinvertebrate community. The spatial arrangement of the sampling sites was responsible for 9.1% of the total variance in littoral benthic community composition, lake morphometry accounted for 4.3% of variation, and microhabitat type accounted for 3.9%. Communities appeared to be affected primarily by morphological alterations to lake shorelines, and their impact was 2.5 times as important as that of eutrophication. The structure of littoral benthic communities was governed by processes acting at several spatial scales from region to lake scale. Thus, several pressures and the various spatial scales at which these act should be taken into account when implementing methods of assessing lake ecological condition based on littoral benthic invertebrates. Region-specific methods for subalpine and volcanic lakes might enhance the validity of assessment of results of morphological alterations and improve management of those water resources." (Authors)]

Ischnura elegans was used as indicator for 'Unmodified sites with macrophytes', and *Sympetrum fonscolombii* for 'Hard altered sites'.] Address: Pilotto, Francesca, Dept of Public Health and Infectious Diseases, Sapienza University of Rome, Piazzale Aldo Moro 5, 00185 Roma, Italy

15447. Pospekhova, N.A.; Regel, K.V. (2015): Morphology and ultrastructure of two schistostomoid cysticercoids (Cestoda: Cyclophyllidea) from the haemocoel of the dragonfly larvae. *Parazitologija* 49(5): 339-351. (in English, with Russian summary) ["Two cysticercoids, belonging to ascocercus type, namely euascocercus and multicercus, were found in haemocoel of dragonfly larvae of the genus *Aeshna* from the lakes of the Magadan Province. The cysticercoid of *Schistostoma* *srivastavae* Raush, 1970 (euascocercus) is formed of the outer (exocyst) and inner (endocyst) envelopes, containing the scolex and larval strobila. The outer and inner surfaces of the exocyst are represented by the tegument covered with microvilli. The microvilli of the outer tegument are restricted by the surface layer, consisting of granular and fibrillar material, and possess different structures at different stages of post-embryonic development. The multicercus of *Mircia* *shigini* (Konyaev et Gulyaev, 2006) is able to multiply asexually by the endogenous budding. The daughters' individuals are formed in the envelope of the multicercus that represents the tegument bearing microvilli. These microvilli are also restricted by the surface layer. The morphology and development of each individual cysticercoid of the multicercus is similar to those of euascocercus. The production of a great amount of cysticercoids, and the presence of the surface layer resembling the laminated layer of *Echinococcus*, relates multicercus to hydatid cysts." 15448. Powney, G.D.; Cham, S.S.; Smallshire, D.; Isaac, N.J.B. (2015): Trait correlates of distribution trends in the Odonata of Britain and Ireland: Southern species benefit from climate warming. *PeerJ PrePrints* 2:e648v1 <http://dx.doi.org/10.7287/peerj.preprints.648v1>: 14 pp. (in English) ["A major challenge in ecology is understanding what enables certain species to persist, while others decline, in response to environmental change. Trait-based comparative analyses are useful in this regard as they can help identify the key drivers of decline, and highlight traits that promote resistance to change. Despite their popularity trait-based comparative analyses tend to focus on explaining variation in range shift and extinction risk, seldom being applied to actual measures of species decline. Furthermore they have tended to be taxonomically restricted to birds, mammals, plants and butterflies. Here we utilise a novel approach to estimate trends for the Odonata in Britain and Ireland, and examine trait correlates of these trends using a recently available trait dataset. We found the dragonfly fauna in Britain and Ireland has undergone considerable change between 1980 and 2012, with 33 and 39% of species showing significant declines and increases respectively. Distribution type was the key trait associated with

these trends, where southern species showed significantly higher trends than widespread and northern species. We believe this reflects the impact of climate change as the increased ambient temperature in Britain and Ireland better suits species that are adapted to warmer conditions. We conclude that northern species are particularly vulnerable to climate change due to the combined pressures of a decline in climate suitability, and competition from species that were previously limited by lower thermal tolerance.... Species that showed the greatest declines included: *Aeshna juncea* and *Sympetrum danae*, while *Anax imperator* and *Aeshna mixta* showed the greatest increases." 15449. Preston, D.B.; Forstner, M.R.J. (2015): Houston Toad (*Bufo* (*Anaxyrus*) *houstonensis*) tadpoles decrease their activity in response to chemical cues produced from the predation of conspecifics and congeneric (*Bufo* (*Incilius*) *nebulifer*) tadpoles. *Journal of Herpetology* 49(2): 170-175. (in English, with Spanish summary) ["Anurans have been shown to reduce their activity in the presence of predation-related chemical cues. We exposed tadpoles of the federally endangered Houston Toad, *Bufo* (*Anaxyrus*) *houstonensis*, to three chemical cues: A no-predation cue produced by the presence of only predatory anisopteran nymphs (*Anax junius*), a conspecific-predation cue produced from the consumption of conspecific tadpoles by *A. junius* nymphs, and a heterospecific-predation cue produced from the consumption of coastal plain toad (*Bufo* (*Incilius*) *nebulifer*) tadpoles by *A. junius* larvae. We measured tadpole activity levels before and after exposure to the cues. Tadpole activity was not influenced by the no-predation cue, but it decreased significantly during exposure to either predation cue. The reduction in activity did not differ significantly between predation cue treatments. These data suggest that: 1) *B. houstonensis* tadpoles will respond to predation, but not the presence of a predator alone. 2) There may be a chemical homology between the predation cues. 3) When developing with *B. nebulifer* tadpoles, *B. houstonensis* may experience negative long-term life historical effects." 15451. Pryke, J.S.; Samways, M.J.; De Saedeleer, K. (2015): An ecological network is as good as a major protected area for conserving dragonflies. *Biological Conservation* 191: 537-545. (in English) ["Highlights: •We compared wallows, ponds and marshes in ecological networks and protected area. •Ecological networks shared 3/4 of dragonfly species with the protected area. •Equal numbers of rarest species occurred in both landscapes. •Proximity of plantation trees had only a minor effect. •Ecological networks are as effective as the protected area for aquatic conservation. Abstract: Freshwaters are highly threatened ecosystems, with agro-forestry being a major threat to sub-tropical wetlands. In the Maputaland–Pondoland–Albany global biodiversity hotspot of South Africa, large-scale ecological networks (ENs) of remnant vegetation have been set aside with the aim of mitigating the adverse effects of plantation forestry. However, the effectiveness of these ENs for maintaining freshwater biodiversity, especially that of still waters, is poorly known. In response, we compare mud wallows of large mammals, ponds and small marshes in an EN with those in an adjacent World Heritage Site protected area (PA) as reference. For this comparison we used dragonfly adults in view of their effectiveness as bioindicators. A total of 47 species was recorded at 105 sites. The EN shared 74% of its species with the PA. However, equal numbers of range restricted species were recorded from the EN and the PA. Five species were recorded as particular to the EN and seven to the PA, probably due to habitat heterogeneity across this type of landscape. Pond size, habitat heterogeneity, elevation and dissolved oxygen were important determinants for species richness and diversity. Proximity of plantation trees had only a minor effect, and then only on species composition. Mud wallows were the poorest habitat in terms of dragonfly diversity, owing to the intense disturbance. Wallows, ponds and marshes were largely complementary in their species composition. Overall, the freshwater system in the EN was a good surrogate for that in the PA, indicating the effectiveness of these ENs for maintaining the dragonfly assemblage." 15456. Ragaei, M.; Sabry, A.H. (2015): Role of color Interference on the insect's cuticle coloration. *International Journal of Science and Research* 4(6): 2306-2314. (in English) ["Interference colours result from the reflection of light from a series of neighbouring interfaces that are separated by distances comparable with a quarter of the wavelength of light. Interference colours are common in some adults of Lepidoptera insects. The integument layers producing interference are formed by modifications of the scales. Each of the blue scales of the *Morpho rhetenor* butterfly, for instance, consists of a flat basal plate carrying a large number of near-parallel vertically aligned ridges that run parallel with the length of the scale. Within each ridge are series of horizontal layers, separated by air spaces. Collectively, the horizontal layers in each adjacent ridge form a series of reflecting surfaces, which are spaced such that a blue colour is produced by interference. Interference colours in other insects are produced by reflection at the interfaces of layers in the cuticle which differ in refractive index. The refractive indices of the alternating layers in the pupa of the danaid butterfly, *Euploea mulciber*, are 1.58 and 1.37. In jewel beetles, *Chrysochroa fulgidissima* (Buprestidae) and tiger beetles, *Cicindela japonica* (Cicindellidae), these layers are in the exocuticle, but in tortoise beetles (Cassidinae) and some butterfly pupae they are in the endocuticle. Interference is responsible for the iridescence of the membranous wings of many different insects, particularly Odonata." (Authors)] Address: Ragaei, M., Pests and Plant Protection Dep. 15457. Rajabi, H.; Ghoroubi, N.; Darvizeh, A.; Dirks, J.H.; Appel, E.; Gorb, S.N. (2015): A comparative study of the effects of vein-joints on the mechanical behaviour of insect wings: I. Single joints. *Bioinspiration & Biomimetics* 10(5) 056003. doi:10.1088/1748-3190/10/5/056003: (in English) ["The flight performance of insects is strongly affected by the deformation of the wing during a stroke cycle. Many insects therefore use both active and passive mechanisms to control the deformation of their wings in flight. Several studies have focused on the wing kinematics, and plenty is known about the mechanism of their passive deformability. However, given the small size of the vein-joints, accurate direct mechanical experiments are almost impossible to perform. We therefore developed numerical models to perform a comparative and comprehensive investigation of the mechanical behaviour of the vein-joints under external loading conditions. The results illustrate the effect of the geometry and the presence of the rubberlike protein resilin on the flexibility of the joints. Our simulations further show the contribution of the spikes to the anisotropic flexural stiffness in the dorsal and ventral directions. In addition, our results show that the cross veins, only in one joint type, help to transfer the stress to the thicker longitudinal veins. The deformation pattern and the stress distribution in each vein-joint are discussed in detail. This study provides a strong background for further realistic modelling of the dragonfly wing deformation." (in English, with Slovenian summary) ["As a part of the Balkan odonatological cooperation, the 2nd Balkan Odonatological Meeting (BOOM 2012) was held in Vojvodina (Serbia). Altogether, between 7. and 12. 8. 2012, 24 localities were surveyed and 34 dragonfly species found. This represents more than half of the hitherto recorded dragonfly species for the country. Significant results include the second record and a new locality of *Aeshna grandis* for Serbia and the first confirmation of successful reproduction of *Anax ephippiger* in the country. New data on several species with a comparably low number of previously published records for Vojvodina, i.e. *Somatochlora meridionalis*, *Cordulia aenea*, *Gomphus flavipes*, *Sympetrum flaveolum*, *Sympetrum vulgatum* and *Lestes dryas*, is also presented and briefly discussed.] Address: Rajkov, S., Bulevar Oslobođenja 115/73, 21101 Novi Sad, Serbia; E-mail: rajkovs@gmail.com

15459. Ramírez-Delgado, J.; López-García, K.; Lara, C.; Serrano-Meneses, M.A. (2015): Wing pigmentation in males of a territorial damselfly: Alternative reproductive tactics, allometry and mating success. *Journal of Insect Behavior* 28(5): 569-581. (in English) ["Alternative reproductive tactics (ARTs) evolve to maximise fitness by favouring alternative phenotypes when high variance in relative fitness occurs amongst individuals. In the damselfly *Hetaerina vulnerata* males occur as either territorial or nonterritorial, depending on whether males acquire and defend an area to which females are attracted for copulation. Territorial males are usually larger, more pigmented and more successful in obtaining copulations than nonterritorial males. Several studies further suggest that territorial males are in overall better condition than nonterritorial ones. Other studies have investigated whether wing pigmentation, a sexual trait in damselflies, scales hyperallometrically with body size, and asked whether this pattern is related to fitness—nonetheless, a clear answer to this question remains elusive. Here we investigate whether i) territorial and nonterritorial males differed in body size and wing pigmentation; ii) body size, wing pigmentation and/or male status (male ART) predicted male mating success; and iii) the allometry of wing pigmentation in territorial and nonterritorial males, and amongst mated and unmated males. We first found that territorial and nonterritorial males did not differ in body size. Second, contrary to what occurs in other damselflies, territorial and nonterritorial males exhibited similar amounts of wing pigmentation. Third, only territory tenure, but not body size or wing pigmentation, predicted male mating success. Finally, with the exception of the relationship exhibited by mated males, which exhibited isometry, wing pigmentation was hyperallometric in all groups of males tested. The latter result suggests that hyperallometry of the sexual trait in this damselfly may not be selectively advantageous." 15460. Randrianandrasana, M.; Berenbaum, M.R. (2015): Edible non-crustacean arthropods in rural communities of Madagascar. *Journal of Ethnobiology* 35(2): 354-383. (in English) ["Entomophagy, the practice of eating insects, is not new in many countries, including Madagascar, where insects have long been part of culinary traditions. Promoting this practice would help in enhancing food security as insects are nutritious and affordable for the majority of the population. Because eating insects is also associated with rural life, we conducted a survey in rural communities of Madagascar from April to June 2013. Diversity of edible, non-crustacean arthropods was assessed for each site using the number of times names of arthropods consumed were mentioned by each household. Approximately 65 morpho-species from seven orders of insects, including Hemiptera, Coleoptera, Lepidoptera, Orthoptera, Hymenoptera, Odonata, and Mantodea, and two orders of arachnids, including Araneae and Ixodida, were recorded as the most frequently consumed arthropods during the survey. Preference rankings differed among sites, possibly depending on the availability of the edible species; information on seasonal availability was also recorded from the informants. When comparing factors influencing food security in rural areas, most of the edible species were found between October and March, a time associated with the lean season and elevated food prices. This pattern demonstrates the importance of entomophagy in food security as Malagasy farmers rely heavily on their subsistence crops for their living. Rearing selected edible insects at a marketable level, combined with other insect-based activities such as sericulture, would further improve food security. Promoting the importance of ethnoentomology would be ultimately leading to more effective sustainability of edible insects and conservation of forests in Madagascar." 15461. Rathod, D.M.; Parasharya, B.M. (2015): Feeding potential of adult dragonflies, *Pantala flavescens* (Fabricius), *Brachythemis contaminata* Fabricius and *Bradinopyga geminata* Rambur (Anisoptera: Libellulidae) on insect pests under laboratory condition. *Journal of Biological Control* 29(2): 85-88. (in English) ["Feeding potential of three dragonfly species was worked out on the basis of numerical value and fresh prey weight under laboratory condition at Anand (Gujarat) during 2013. Adult dragonflies, viz., *Pantala flavescens*, *Brachythemis contaminata* and *Bradinopyga geminata* were used as predator and *Nilaparvata lugens*, *Aphis craccivora* and *Aedes* sp. were used as prey. Daily biomass consumption of *P. flavescens*, *B. contaminata* and *B. geminata* were 224.51 mg, 149.35 mg and 169.34 mg respectively. The prey numbers consumed by each dragonfly species were significantly different. However, irrespective of prey species biomass consumption was the same. Feeding potential of the dragonflies was positively correlated with their body weight. Feeding potential of females of *P. flavescens* and *B. contaminata* was slightly

higher than their respective males." (Authors)] Address: Rathod, D.M., AINP on Agricultural Ornithology, Anand Agricultural University, Anand-388 110, Gujarat, India

15462. Rathod, P.P.; Manwar, N.A.; Raja, I.A. (2015): Visual deception in oviposition site selection in female dragonfly *Bradinopyga geminata* (Rambur) Libellulidae: Anisoptera. *International Journal of Advanced Research* 3(5): 562-565. (in English) ["Vision is the most developed sense in dragonfly, uses for habitat selection and mate recognition. The present investigation explains the role of visual sense in selection of oviposition site in dragonfly. This study was reported in female of *Bradinopyga geminata* which observed to be deceived by the shining black surfaces as water bodies and selected them as its ovipositing site. In our study on reproductive behaviour, we observed ovipositing *B. geminata* females, instead of water body, selected dark brown shining colored flag base, the moving shiny black wheels of heavy vehicles and the front screen glass of a car as its oviposition site and deposited the eggs. Thus it is found that the female of dragonfly *B. geminata* very much depends on its visual sense in selection of its oviposition site and capable of misguided in this regard." 15463. Reborá, M.; Piersanti, S.; Salerno, G.; Gorb, S. (2015): The antenna of a burrowing dragonfly larva, *Onychogomphus forcipatus* (Anisoptera, Gomphidae). *Arthropod Structure & Development* 44(6, Part A): 595-603. (in English) ["Highlights: •The larva of the dragonfly *Onychogomphus forcipatus* has a burrowing lifestyle. •This is the first ultrastructural investigation (SEM, TEM) on its antennal sensilla. •Numerous mechanoreceptors and one possible chemoreceptor are described. •The mechanoreceptors are mostly filiform hairs presumably for current detection. •This is the first report of an antennal gland in palaeopteran insects. Abstract: The larva of *O. forcipatus* has a burrowing lifestyle and antennae composed of four short and broad segments (scape, pedicel and a two-segmented flagellum). The present ultrastructural investigation revealed that different sensilla and one gland are located on the antenna. There is a great diversity of mechanoreceptors of different kinds. In particular club-shaped sensilla, sensilla chaetica, and tree-like sensilla show the typical structure of bristles, the most common type of mechanoreceptors, usually responding to direct touch, while numerous long thin thorny trichoid sensilla show a morphology recalling the structure of filiform hair mechanoreceptors. The latter ones are presumably important in larval Odonata for current detection and rheotactic orientation, especially in a burrowing species. On the smooth apical cuticle of the second flagellar segment, three structures are visible: (1) a small ellipsoidal pit hosting a convoluted peg, the morphology of which resembles that of a typical chemoreceptor (even if pores are lacking), (2) a couple of small pits (not investigated under TEM), and (3) one wide depression with spherical structures, the internal morphology of which lets us assume that it is a gland with unknown function. This is the first report of an antennal gland in palaeopteran insects." (Authors)]

(2015): Dragonflies (Odonata) from the Taquari River valley region, Rio Grande do Sul, Brazil. *Check List* 11(5): 1740: 6 pp. (in English) ["A survey of Odonata was carried out in the central region of the state of Rio Grande do Sul: the Taquari River valley. This region was originally covered by deciduous and Semi-deciduous Atlantic Forest, which today only exist in a highly fragmented environment mainly due to agricultural activities. Our survey was conducted in 12 municipalities from this region, between March 2011 and April 2013. Aiming a general overview of the species composition, our sampling sites included lakes, bogs, small streams and river sections, all inside or surrounded by small forest fragments or forest areas. Fifty species of Odonata were collected comprising 29 genera and seven families. The dominant families were Libellulidae (40%) and Coenagrionidae (36%), while Aeshnidae, Gomphidae and Lestidae each only comprise 6% of the total number of species. The findings revealed the presence of a highly diverse odonate assemblage, mainly represented by generalist species in human disturbed fragments and a few forest specialist species in the best preserved remnants only." 15466. Richards, D.R.; Warren, P.H.; Moggridge, H.L.; Maltby, L. (2015): Spatial variation in the impact of dragonflies and debris on recreational ecosystem services in a floodplain wetland. *Ecosystem Services* 15: 113-121. (in English) [Highlights: •We model spatial variation in recreational experiences using three steps. •The net quality of recreational experiences varies at a fine spatial scale. •The noticeability of habitat components strongly impacted visitor experiences. •Noticeability is important in the analyses of recreational ecosystem services. Abstract: Recreation is an important ecosystem service. The interaction between people and habitat components is rarely considered in the analyses of recreational experiences, making it difficult to predict what people will experience. In this study we develop a modelling framework that describes three stages of interaction between people and habitats. This framework considers: (1) the distribution of habitat components in the environment, (2) the proportion of the available components that

visitors notice, and (3) the net impact of multiple components on the quality of the recreational experience. The model was applied to a case study river floodplain, and was used to estimate visitor exposure to a combination of positive habitat components (dragonflies) and negative components (debris). The model provided an index of net impacts on experience quality that showed spatial variation across the floodplain, and this analysis highlighted areas that would deliver more positive experiences to visitors. The results of a sensitivity analysis indicated that neglecting the noticeability (observation rate) of habitat components resulted in different predictions. It is therefore important that the noticeability of habitat components is considered during analyses of recreational experiences, and recreational ecosystem service valuations." 15467. Richards, S.J.; Theischinger, G.; Tamarua, W. (2015): Chapter 3: Dragonflies and damselflies (Odonata) of Manus and Mussau Islands. In: Whitmore N. (editor) 2015. A rapid biodiversity survey of Papua New Guinea's Manus and Mussau Islands. Wildlife Conservation Society Papua New Guinea Program. Goroka, PNG: 27-30. (in English) ["A total of 21 species of Odonata were documented from Manus and Mussau Islands, comprising 9 damselflies and 12 dragonflies. Nineteen of the 21 species were found on Manus and 12 were found on Mussau. One damselfly species in the genus *Drepanosticta* (family Platystictidae) from Manus Island is new to science. No species listed by the IUCN as Data Deficient, or in any threatened category, was detected. The odonate fauna of both Manus and Mussau islands is dominated by widespread species, a feature common to remote oceanic islands. However two species of damselflies, the recently described *Nososticta manuscola* Theischinger and Richards (in press) and the new *Drepanosticta* reported for the first time here, appear to be endemic to Manus Island. Management of the forests in central Manus to ensure long-term persistence of the clear streams and riparian vegetation inhabited by the two endemic species is a high conservation priority. Surveys of the interior of Mussau Island should also be conducted to determine whether additional, and potentially new and endemic, species occur there away from the coastal fringe." (in English) ["An inventory of Odonata was carried out in six districts of central Gujarat from 2012 to 2014. A total of 42 species belonging to 27 genera, under seven families and two suborders were recorded. A total of 16 species of Zygoptera and 26 species of Anisoptera were recorded. Anand District was surveyed intensively and as a result a maximum of 35 species was recorded (Dragonfly 22 and Damselfly 13), whereas less intensively surveyed districts, i.e., Panchmahal (17) and Dahod (16) had comparatively low species richness. Twenty-two species are being reported for the first time from central Gujarat, raising the total list of odonates to 48. Six species reported in an earlier survey were not encountered during this study. Seven species namely, *Copera marginipes*, *Pseudagrion microcephalum*, *Anaciaeschna jaspidea*, *Anax immaculifrons*, *Epophthalmia vittata*, *Brachydiplax sobrina*, *Tramea basilaris burmeisteri* are being recorded for the first time from Gujarat State. Hence, now the checklist of the odonates of Gujarat is raised to 65 species." (Authors)] Address: Rohmare, V.B., At PO Pohegaon, Kopargaon Taluka, Ahmednagar, Maharashtra 423605, India. 15472. Sadeghi, S.; Bakhshi, Y.; Dumont, H. (2015): Wing shape variation among central Asian populations of *Calopteryx splendens*. *Taxonomy and Biosystematics* 7(23): 13-26. (in Persian, with English summary) ["We applied geometric morphometric techniques to explore the morphological variation of forewings between 10 Asian *Calopteryx splendens* populations including Azerbaijan, Russia, Turkey, Uzbekistan, Iran, Turkmenistan, Tajikistan, Kazakhstan, and Kyrgyzstan countries. We focused on the study of the phenetic relationships among the populations in central Asia. The results showed that the northern and western populations of Iran had the largest and smallest centroid

size of the wings, respectively. In addition, differences among wing shape of the 10 studied populations of *C. splendens* were significant. Our results indicated that Tajikistan population has quite distinct divergence and also Turkmenistan and northern part of Iran populations both were very close each other and located in a separate clade. The Azerbaijan, Russia, Turkey, Uzbekistan, west Iran, Kazakhstan and Kyrgyzstan populations were revealed to be more interrelated to each other, although Kazakhstan and Kyrgyzstan populations seems to be more closer than the other." (in English) ["*Wolbachia* are maternally inherited bacterial endosymbionts of arthropods distributed among a wide range of hosts. It is now well known that they induce reproductive manipulations in their arthropod hosts by various phenotypic effects. The objective of the present study was to investigate *Wolbachia* infection among the insect order Odonata comprising 16 species from 5 families. Fifteen odonate species representing five families were found to harbour *Wolbachia* with the overall infection rate of 70%, out of which fourteen species are reported for the first time. According to multilocus sequence typing (MLST) data and phylogenetic analysis, all odonate *Wolbachia* species belong to supergroup F, except *Trithemis pallindinervis*, which belongs to supergroup B. MLST data reveal 20 new, highly similar STs (99.32 ± 0.34). We found a high rate of *Wolbachia* infection in Odonata of India, which indicates importance of this association. The characterization of these *Wolbachia* strains promises to lead to a deeper insight into this interaction, which is essential for further studies based on their phenotypic effects. The study suggests that all the characterized *Wolbachia* STs are totally new and arise as a result of point mutation." 15474. Sampath, P., Liao, H., Curtis, Z., Li, S., and Deloria, C. (2015): Modeling fen hydrology to inform recovery of the endangered Hine's Emerald Dragonfly. *J. Hydrol. Eng.*, 10.1061/(ASCE)HE.1943-5584.0001314 , 05015029: 12 pp. (in English) ["It is generally recognized that fens and the rare species they support can only be effectively managed and protected by treating them as part of a larger, connected groundwater system. However, this underlying groundwater

system is often not well understood. In this research, a geographic information system (GIS)-enabled, hierarchical modelling approach was applied to simulate the multiscale groundwater flow systems for several critical habitat units of the endangered *S. hineana* in Michigan. In particular, models for six habitat units were developed and calibrated to static water level measurements. Reverse particle tracking was used to trace source water and delineate the groundwater contribution areas for the habitat units. The results reveal that the units obtain water from regional groundwater mounds through direct or cascading connections. The travel time for groundwater from the mounds to reach the habitat units varied between 25 days and almost 11 years. These findings suggest that the current approach to fen conservation must be reassessed, from the protection of individual fens to conservation of the broad recharge areas and the multiple fens they support." 15476. Santana, H.S.; Silva, L.C.F.; Pereira, C.L.; Simião-Ferreira, J.; Angelini, R. (2015): The rainy season increases the abundance and richness of the aquatic insect community in a Neotropical reservoir. *Brazilian Journal of Biology* 75(1): 144-151. (in English, with Portuguese summary) ["Alterations in aquatic systems and changes in water levels, whether due to rains or dam-mediated control can cause changes in community structure, forcing the community to readjust to the new environment. This study tested the hypothesis that there is an increase in the richness and abundance of aquatic insects during the rainy season in the Serra da Mesa Reservoir, with the premise that increasing the reservoir level provides greater external material input and habitat diversity, and, therefore, conditions that promote colonization by more species. We used the paired t test to test the differences in richness, beta diversity, and abundance, and a Non-metric Multidimensional Scaling (NMDS)

was performed to identify patterns in the community under study. Additionally, Pearson correlations were analyzed between the richness, abundance, and beta diversity and the level of the reservoir. We collected 35,028 aquatic insect larvae (9,513 in dry period and 25,515 in the rainy season), predominantly of the Chironomidae family, followed by orders Ephemeroptera, Trichoptera, and Odonata. Among the 33 families collected, only 12 occurred in the dry season, while all occurred in the rainy season. These families are common in lentic environments, and the dominance of Chironomidae was associated with its fast colonization, their behavior of living at high densities and the great tolerance to low levels of oxygen in the environment. The hypothesis was confirmed, as the richness, beta diversity, and abundance were positively affected by the increase in water levels due to the rainy season, which most likely led to greater external material input, greater heterogeneity of habitat, and better conditions for colonization by several families." 15478. Schiel, F.-J.; Buchwald, R. (2015): Contrasting life-history patterns between vernal pond specialists and hydroperiod generalists in *Lestes* damselflies (Odonata: Lestidae). *Odonatologica* 44(3): 349-374. (in English) ["The aim of our study was to identify life-history mechanisms enabling typical inhabitants of vernal ponds to complete their larval development under the time constrained conditions of their temporary larval habitats. For that reason we compared both hatching phenology and larval development of vernal pond specialists *Lestes barbarus*, *L. dryas*, and *L. macrostigma* with those of the closely related hydroperiod generalists *L. sponsa*, *L. virens*, and *L. viridis* under seminatural conditions. As hypothesized, we found vernal pond specialists of the genus *Lestes* to cope with the short water coverage of their typical larval habitats by the following developmental traits: a) an early hatching date in *L. dryas* and *L. barbarus*, b) large second-stadium larvae, which have to grow less and with fewer larval stadia than the hydroperiod generalists *L. dryas* and *L. macrostigma*, c) a short larval development time in *L.*

macrostigma and d) higher growth rates in *L. dryas* and *L. barbarus* than in the other species. Degree day sums in vernal pond specialists were significantly lower than in their less specialized counterparts. This means, that they would have grown faster than hydroperiod generalists, if thermal conditions during larval development were identical in all species. Due to these developmental adaptations, larvae of *L. dryas* and *L. barbarus* emerged significantly earlier in the course of year than both *L. macrostigma* and the three hydroperiod generalists. Unexpectedly, none of the three studied vernal pond specialists has evolved all of these particular adaptations. This may be because of the close ecological relationship within the genus *Lestes*, and the studied species being generally characterized by univoltine life cycles and fast larval development, which enables all of the European species to reproduce in temporary ponds." (Authors)] Address: Schiel, F.-J., Inst. Naturschutz und Landschaftsanalyse, Turenenweg 9, D-77880 Sasbach, Germany. E-mail: Franz-Josef.Schiel@INULA.de

15479. Schiel, F.-J.; Buchwald, R. (2015): Hatching phenology of Odonata species inhabiting temporary and permanent water bodies (Odonata: Lestidae, Aeshnidae, Libellulidae). *International Journal of Odonatology* 18(2): 105-123. (in English) ["The hatching phenology of 15 Odonata species was studied under seminatural conditions to find out how the hatching modes of typical species of summer dry temporary waters (vernal ponds) differ from those of species inhabiting both permanent and temporary waters. We attempt to answer the following questions. (1) Do vernal pond species hatch earlier in the year than congeneric permanent water species? (2) Can hatching in vernal pond species be delayed under unsuitable environmental conditions, like drought? (3) Can eggs of vernal pond species survive for more than one year? Larvae of vernal pond species, *Aeshna affinis*, *Lestes barbarus*, *L. dryas* and *Sympetrum flaveolum*, hatched significantly earlier than their permanent water counterparts *A. mixta*, *L. sponsa*, *L. virens*, *L. viridis*, *S. danae*, *S. depressiusculum*, *S. meridionale*, *S. sanguineum*, *S. striolatum* and *S. vulgatum*. Only one vernal pond species, *L. macrostigma*, did not show this early hatching. In both vernal pond and permanent water species hatching succession of different clutches of each species varied, which may reflect genotypic differences. In both vernal pond species and permanent water species hatching was delayed when eggs were kept on moist filter paper – simulating drought – instead of being put into water. The hatching success of two vernal pond species and of four out of five studied permanent water species was reduced significantly by keeping eggs on moist filter paper. Survival of eggs for more than one year could not be proved under temperature conditions resembling those in nature." (Authors)] Address: Schiel, F.-J., Inst. Naturschutz und Landschaftsanalyse, Turenenweg 9, 77880 Sasbach, Germany. E-mail: Franz-Josef.Schiel@INULA.de

15480. Schmidt, E. (2015): Die Odonatenfauna eines Kiefernheide-Weiher im Teichgut Hausdülmen (Dülmen, Westmünsterland, NRW). *Libellula* 34(1/2): 59-72. (in German, with English summary) ["The dragonfly fauna of a pine

heath pond at a fish farm in North Rhine-Westphalia – 200 excursions between 1991–2014 are the base of an investigation of the dragonfly fauna of a pine heath pond in the cretaceous Haltern sands, north Westphalia, near a fish pond farm. The pond is surrounded by pine wood, has a dark, acid bogwater, at the bank with a drying out belt of *Juncus effusus* and mosses between the reeds. Formerly there had been *J. bulbosus* mats in front of this belt, which usually dried up in summer. After damming the outflow ditch the water level of the pond became permanent, but the floating vegetation (*J. bulbosus* mats) decreased. 31 species of Odonata had been found (in the neighbouring fish farm additional 13 species). *Leucorrhinia dubia* was the only bog species, confined to floating *Sphagnum* mats and therefore only in single specimens, lost since 2006. Also the four species with preference to heath ponds (*Aeshna juncea*, *Sympetrum danae*, *L. rubicunda*, also *Sympecma fusca*.) became suboptimal, but steadily breeding; for *S. fusca* the pond was a regional breeding centre, and favoured f.i. the (temporary) breeding at the carp breeding ponds. As usual three ubiquitous (*Lestes sponsa*, *Enallagma cyathigerum*, *Libellula quadrimaculata*) are breeding at least in middle density. Eight ubiquitous had been usually breeding, ten species had been more or less usually guests from the fish pond farm and its creeks. Four species with bog preference (*L. virens*, *Ceriatagrion tenellum*, *L. pectoralis*, *Orthetrum coerulescens*) had been only rare guests. A speciality was *S. depressiusculum*. This species in this Atlantic region of Germany is confined to the special conditions of carp breeding ponds. It has a strong preference to low reeds for hunting, resting, and precopulation. This is given by the *Juncus effusus*-belt of the heath pond. So the species came to the belt usually in middle density with reproduction activities, but successful (emergence) only in some years. Thus the investigation shows a remarkable dragonfly exchange between the pineheath pond and the fish pond farm." (Author)] Address: Schmidt, E.G., Coesfelder Str. 230, 48249 Dülmen, Germany

15481. Schneider, T.; Schneider, E.; Schneider, J.; Vierstraete, A.; Dumont, H.J. (2015): *Aeshna vercanica* sp. nov. from Iran with a new insight into the *Aeshna cyanea*-group (Odonata: Aeshnidae). *Odonatologica* 44(1/2): 81-106. (in English) ["*Aeshna vercanica* sp. nov. is described and illustrated. The male holotype and four male paratypes were collected on 15-vii-2013 in the Hyrcanian forest of the Alborz Mountains, Mazandaran province, northwestern Iran. A specimen collected on 29-vi-2002 in the Talysh Hills, Lankoran area, Azerbaijan, also belongs to the new species. In July 2014 the species, including females, was recorded again at the type locality and additionally ca 400 km further east in Golestan province. Males are similar to *Aeshna cyanea* in the structure of genitalia and terminalia but differ in head morphology, pterostigma length, colour pattern, and behaviour. Females have small abdominal blue or turquoise postero-median dorsal spots which are absent on S9 and S10, thin green antehumeral stripes, a less robust appearance than females of *A. cyanea*, and are more slender and longer. The range of *A. vercanica* sp. nov. covers the Hyrcanian forest along the southern margin of the Caspian

Sea. Analysis of the barcoding COI sequence of DNA confirmed that *A. vercanica* sp. nov. is separated from *A. cyanea* by a genetic distance of more than 4 %. The ITS gave a similar result. A haplotype map could not derive *A. vercanica* sp. nov. directly from *A. cyanea*. They are thus related but different species, and we suggest the common ancestor lived in pre-Pleistocene times. Analysis of *A. cyanea* specimens from across its range revealed two infraspecific clades. The western one extends from the Maghreb to Central Europe; the eastern one from the Caucasus to Eastern Europe, a common scenario for post-glacial invaders. A molecular comparison of the species pair *A. juncea* and *A. subarctica* showed these to be even more closely related than *A. cyanea* and *A. vercanica* sp. nov." 15482. Schneider, T.; Ikemeyer, D.; Dumont, H.J. (2015): New records of dragonflies (Odonata) from Belutschistan-e-Sistan province in Iran. *Zoology in the Middle East* 61(3): 288-290. (in English) [Data of the following species are presented: *Trithemis pallidinerve*, *Brachythemis contaminata*, *Platynemis dealbata*, *Ischnura evansi*, *I. nursei*, *I. pumilio*, *I. rubilio*, *Pseudagrion decorum*, *Diplacodes lefebvrei* and *Selysiothemis nigra*] Address: Schneider, T., Arnold-Knoblauch-Ring 76, 14109 Berlin, Germany. E-mail: thomas.rs@gmx.de

15483. Schröter, A.; Seehausen, M.; Kunz, B.; Günther, A.; Schneider, T.; Jödicke, R. (2015): Update of the Odonata fauna of Georgia, southern Caucasus ecoregion. *Odonatologica* 44(3): 279-342. (in English) ["A total of 63 odonate taxa were recorded in Georgia during nationwide surveys in June–July 2014, and June and July–August 2015, corresponding to at least 85 % of the country's Odonata fauna. For the majority of species information from Georgia is provided in English language for the first time. *Selysiothemis nigra* is a new addition to the country's list. The occurrence of *Chalcolestes parvidens* is confirmed and previous records from Georgia listed as *Lestes viridis* are doubted and believed to pertain to *parvidens*. The second and third records only for *L. macrostigma* are presented. Individuals intermediate between *Enallagma cyathigerum* and *E. c. risi* are reported from Georgia for the first time. As to Georgian *Lestes virens*, the infraspecific taxonomy is critically discussed, with special reference to Central Asian forms described as ssp. *marikovskii*. It is recommended to avoid any further splitting into inadequately defined subspecies, as the variability of eastern forms from Central Europe towards Central Asia can be better described as clinal variation within the ssp. *vestalis*. In consequence, the name *marikovskii* is regarded as a junior synonym of *vestalis*: *Lestes virens vestalis* Rambur, 1842 = *L. virens marikovskii* Belyshev, 1961, syn. nov. The diversity of taxa within the *Calopteryx splendens* complex in the Caucasus region is considered to comprise in fact three subspecies in Georgia: ssp. *intermedia*, ssp. *tschaldirica*, and ssp. *mingrelica*. Despite of transition zones and hybridisation each subspecies represents in toto a spatially clearly delimited unit. In ssp.

intermedia androchrome females frequently occurred in the Kakheti region in the east of Georgia. The distinct female colour form 'feminalis' of *Calopteryx virgo* is illustrated for the first time and the availability of the name *Calopteryx virgo* var. *feminalis* Bartenev, 1910 is critically discussed. For a number of species the first information from Georgia is provided since their discovery over a century ago, such as *Coenagrion armatum*, *Aeshna serrata*, and *Onychogomphus assimilis*; for *Coenagrion lunulatum* and *C. scitulum* the first data since over 75 years are presented. *Coenagrion ponticum* was recorded throughout the country and at least at two sites found to reproduce syntopically with *C. puella*. New information is provided for the little known *Coenagrion vanbrinkae*, including a formerly unknown pink colour morph of reproductive females. The infraspecific taxonomy of *Ischnura elegans* is critically discussed, with special reference to the taxa *pontica* Schmidt, 1938 and *ebneri* Schmidt, 1938. In addition, new records of *Pyrrhosoma nymphula* and *Coenagrion pulchellum*, both being rare in the Caucasus region, are given. The presence of distinct *Gomphus schneiderii* in Georgia is confirmed as well as the continuous presence of *Gomphus ubadschii* at the Rioni River over 80 years after its description under the homonym »*Gomphus flavipes* var. *lineatus* var. n.«. *Onychogomphus assimilis* and *O. flexuosus* were found to be abundant in the eastern half of the country suggesting that Georgia is an important global stronghold for both threatened species. Males of *Caliaeschna microstigma* exhibited a distinctive tendency for reduced ante-humeral stripes, leaving only a small bluish patch at the posterior part in some males. Vital populations of *Libellula pontica*, endemic to the East Mediterranean, were found and the species is assumed to be well established in the Kakheti region in the East of the country." 15484. Schütte, C.; Müller, O. (2015): Dorsolateral cuticular outgrowths in second stadium larvae of *Gomphus flavipes* (Odonata: Gomphidae). *International Journal of Odonatology* 18(1): 65-69. (in English) ["Second and third stadium larvae of *Gomphus flavipes* have dorsolateral cuticular outgrowths in the form of small basal tubercles bearing fan-shaped setae. These sensilla are aligned in two rows on each side of the thorax and abdomen. European species of *Gomphus*, *Onychogomphus* and *Ophiogomphus* that we examined lack these structures, having instead, at most, short hairlike setae in double rows. The fan-shaped setae of *G. flavipes* are present only in second and third stadia, apparently being lost later in larval development. We speculate that this loss might be due to changes in microhabitat or might be some kind of phylogenetic constraint." (Authors)] Address: Schütte, C., Bindestr. 16, D-38162 Weddel, Germany. E-mail: c.schuette@lk-wf.de

15485. Segev, O.; Rodríguez, A.; Hauswaldt, S.; Hagemann, K.; Vences, M. (2015): Flatworms (*Schmidtea nova*) prey upon embryos of the common frog (*Rana temporaria*) and induce minor developmental acceleration. *Amphibia-Reptilia* 36(2): 155-163. (in English) ["Amphibians vary in

the degree of pre-metamorphic developmental plasticity in response to risk of predation. Changes in hatching time and development rate can increase egg or tadpole survival respectively by shortening the duration of the more vulnerable stages. The intensity of predator induced developmental response and its direction, i.e. delayed, accelerated, or none, varies considerably between amphibian and predator species. We surveyed freshly deposited clutches of the European common frog *Rana temporaria* in a population in Braunschweig, Germany and found that 62% (N = 20) of the clutches contained planarians (*Schmidtea nova*), with an average of 3.94 ± 0.79 and a maximum of 13 planarians per clutch. A laboratory predation experiment confirmed that this planaria preys on *R. temporaria* eggs and early embryos. We further exposed freshly laid egg masses to either free, caged, or no planarians treatments using floating containers within a breeding pond where the two species co-occur. After 10 days exposure, embryos showed developmental stages 14-25 along the Gosner scale with statistically significant positive effects of both predator treatments. The observed effect was rather slight as predator-exposed individuals showed an increase by a single Gosner stage relative to those raised without planarians. The detected trend suggests that direct and indirect cues from flatworms, rarely considered as anuran predators, might induce a developmental response in *R. temporaria* early developmental stages." (Authors) The paper includes many references to Odonata.] Address: 1Institute of Evolution, University of Haifa, Mt. Carmel, Haifa 31905, Israel; 2Zoologisches Institut, Technische Universität Braunschweig, Mendelssohnstr. 4, D-38106 Braunschweig, Germany

15486. Seifert, N.; Koschkar, S.; Schmitz-Ornés, A. (2015): Diet of Baillon's Crakes *Zapornia pusilla*: Assessing differences in prey availability and consumption during the breeding season in the Senegal River Delta, West Africa. *Acta Ornithologica* 50(1): 69-84. (in English) ["The Baillon's Crake *Zapornia* (*Porzana*) *pusilla* is considered as one of the least known Rallidae species of the Palaearctic. Very little information exists about its ecological requirements and knowledge on diet refers to very few observations. Based on the analysis of faecal samples (N = 59) from two study sites in Djoudj National Park (NW Senegal), we describe the major diet components and examine how seasonal and environmental factors influence its dietary composition. All faeces contained remains of invertebrates. Coleopterans were the most frequent prey items with an occurrence in 95% of the samples. Other important food items were: Odonata (82%), Araneae (78%), Nematocera (59%), and Brachycera (44%). Remains of gecko skin were the only evidence for vertebrate prey. 75% of the faeces contained plant matter, especially seeds of *Eleocharis mutata* which constituted in some individuals > 90% of the sample content. Generalized linear models (GLMs) were used to assess whether occurrence of prey items was an effect of selection or environmental variation, considering both consumed items as well as prey availability. Sweep netting was used to provide an estimate of relative abundance of poten-

tial invertebrate prey. Despite pronounced seasonal changes in temperature and humidity, models revealed a lower influence of meteorological variables on prey composition and availability. Rather we found water level, date and site having the highest impact in the models. In contrast to decreasing diversity of available food items in the course of the season, diversity in the faeces remained constant indicating Baillon's Crakes prey less selectively when resources diminish. Furthermore, diversity of Baillon's Crakes' diet was lower at higher water levels, suggesting stronger selectivity when prey abundances are high as implied by positive relationships of several invertebrate groups with water level. Despite the rapidly declining water levels and decreasing abundances of e.g. Nematocera, Odonata and Mollusca in the course of the season, we found no clear shift from aquatic to a more terrestrial dominated composition of taxa in the birds' diet. This might be due to the selection of profitable prey such as araneans or molluscs but could also be explained by better accessibility due to physical changes in the habitats e.g. in the case of consumed Odonata and Saltatoria. High disintegration of invertebrates in the faeces rendered quantification of prey items impossible. Biomass estimates could support the assessment of specialization of the Baillon's Crakes as well as the detection of seasonal succession of the wetlands' biotic communities." 15489. Shaffery, H.M.; Relyea, R.A. (2015): Predator-induced defenses in five species of larval *Ambystoma*. *Copeia* 103(3): 552-562. (in English) ["While predator-induced plasticity has been demonstrated in a wide range of organisms, relatively few data exist to compare differences among species. In studies of predator-induced plasticity in amphibians, larval anurans have been widely examined, but there are fewer data for larval salamanders. We sought to examine morphological and behavioural defenses in larvae of five species of *Ambystoma* salamanders. We raised five species of larval mole salamanders (*A. barbouri*, *A. gracile*, *A. laterale*, *A. maculatum*, *A. tigrinum*) in separate lab experiments and exposed them to predator cues from larval dragonflies (*Anax junius*). Salamanders did not vary in their refuge use during the experiment, but *A. gracile*, *A. laterale*, and *A. tigrinum* reduced their activity in the presence of predators early in development. Dragonfly (*Anax junius*) cues induced relatively few morphological changes across species: *A. barbouri* developed relatively large heads and deep tails, *A. gracile* and *A. laterale* developed relatively shorter heads, and *A. maculatum* developed relatively wider heads and shorter tails. Our results suggest that behavioural and morphological defenses in *Ambystoma* are highly variable among species and they appear to be less plastic than tadpoles and other salamander species." 15490. Sharkey, C.R.; Partridge, J.C.; Roberts, N.W. (2015): Polarization sensitivity as a visual contrast enhancer in the Emperor dragonfly larva, *Anax imperator* (Leach, 1815). *Journal of Experimental Biology* 218: 3399-3405. (in English) ["Polarization sensitivity (PS) is a common feature of invertebrate visual systems. In insects, PS is well known for its use in several different visually guided behaviours, particularly navigation and habitat search. Adult dragonflies use the polarization of light to find water but a role for PS in aquatic dragonfly larvae, a stage that inhabits a very different photic environment to the adults, has not been investigated. The optomotor response of the larvae of the Emperor dragonfly, *Anax imperator*, was used to determine whether these larvae use PS to enhance visual contrast underwater. Two different light scattering conditions were used to surround the larval animals: a naturalistic horizontally polarized light field and non-naturalistic weakly polarized light field. In both cases these scattering light fields obscured moving intensity stimuli that provoke an optokinetic response in the

larvae. Animals were shown to track the movement of a square-wave grating more closely when it was viewed through the horizontally polarized light field, equivalent to a similar increase in tracking ability observed in response to an 8% increase in the intensity contrast of the stimuli. Our results suggest that larval PS enhances the intensity contrast of a visual scene under partially polarized lighting conditions that occur naturally in freshwater environments." 15491. Sigutova, H.; Sigut, M.; Dolny, A. (2015): Intensive fish ponds as ecological traps for dragonflies: an imminent threat to the endangered species *Sympetrum depressiusculum* (Odonata: Libellulidae). *Journal of Insect Conservation* 19: 961-974. (in English) ["The concept of ecological traps, in which animals settle in low-quality habitats, is well-established. Dragonflies are a good model for investigating the effects of ecological traps because their habitat selection process can be directly observed. Unfortunately, most such studies focus on oviposition on artificial materials, such as car surfaces, gravestones, and plastic foils, which results in complete mortality of the clutch. It remains unclear to what extent intensive fish ponds, ubiquitous in the European agricultural landscape, act as ecological traps for some dragonfly species and how they influence their vulnerability. We investigated the effects of putative ecological traps on the threatened dragonfly *S. depressiusculum* and the common closely related species *S. sanguineum* in a Central European agricultural landscape. Observations of adult behaviour were used to parameterize GLMs examining the attractiveness of five fish ponds (three fish breeding and two intensive) to each species. We also counted exuviae at each pond as a measure of each species' survival. We used GLMMs to determine which factors affected selection of oviposition sites and the environmental factors resulting in ecological traps for each species. All five ponds were attractive to ovipositing pairs of both species, although they were largely unsuitable for subsequent development (four for *S. depressiusculum* and two for *S. sanguineum*). Our results provide evidence that intensive fish ponds act as ecological traps for both species. We believe that cutting of the vegetation surrounding trap habitats could be an effective way to decrease their attractiveness to a wide range of dragonfly species." (Authors)] Address: Šigutová, Hana, Department of Biology and Ecology/Institute of Environmental Technologies, Faculty of Science, University of Ostrava, Chittussiho 10, 710 00 Ostrava, Czech Republic, E-mail: sigutova.hanka@gmail.com

15492. Simaika, J.P.; Samways, M.J. (2015): Predicted range shifts of dragonflies over a wide elevation gradient in the southern hemisphere. *Freshwater Science* 34(83): 1133-1143. (in English) ["Human-induced climate change is among the greatest threats to biodiversity, especially when coupled with habitat destruction. For an already water-stressed country like South Africa, changes in temperature

and precipitation regimes, coupled with increasing water demands, are likely to lead to losses in biodiversity. Dragonflies are a well-studied surrogate taxon for aspects of freshwater biodiversity. We created species distribution models for 14 dragonfly species, and predicted the changes in species richness, extent of occurrence, and habitat suitability for the years 2050 and 2080 in South Africa, a poorly studied area for range-change predictions for insects. Model predictions for 2 different emissions scenarios suggest that at least 2 species will be lost from the area by 2050, and 3 by 2080. All are widespread Afrotropical species, but with narrow elevation ranges in South Africa. Only 1 species is predicted to benefit greatly from climate change. The remaining species are predicted to persist with reduced extents of occurrences at higher elevations. Most species we studied (12 of 14) thrive in artificial environments. Therefore, to a certain extent, loss in connectivity is unlikely to play a role for these species. However, the 2 stream specialists that occur in the area are particularly vulnerable because of loss of habitat. Species that currently occur farther north in southern Africa and South Africa also are likely to move southward in the future. Thus, species richness may not necessarily decrease, but replacement of species within communities will be significant." 15498. Sniegula, S.; Golab, M.J.; Johansson, F. (2015): Time constraint effects on phenology and life history synchrony in a damselfly along a latitudinal gradient. *Oikos* 125: 414-423. (in English) ["In organisms with complex life cycles living in seasonal environments, the synchronisation of phenological events is important from the ecological and evolutionary perspectives. Life history transitions should be synchronised to a greater degree at northern latitudes. We quantified hatching and emergence timing and synchrony in the obligate univoltine damselfly *Lestes sponsa* along a latitudinal gradient covering its entire north-south range in Europe. In our first experiment, populations from different latitudes were grown in separate climate chambers simulating temperature and photoperiod conditions occurring at their sites of origin. Northern populations expressed early and high synchronous hatching and emergence, central populations intermediate, and southern populations late and low synchronous hatching and emergence. This pattern was expressed at both population and full-sibling family levels, indicating stronger selection for timing and synchronisation in the north compared to the south. In our second experiment, populations from all latitudes were reared in conditions simulating an average temperature and photoperiod over the latitudinal gradient. Interestingly, the pattern of timing and synchronisation was reversed with respect to latitude when compared to the pattern shown in the first experiment, indicating the importance of environmental factors in shaping phenological events. Our results indicate strong selection for timing and synchronisation of life history events at northern latitudes, caused by time constraints.

Our results also show that it is important to use as natural conditions as possible in experiments on life history shifts in organisms with complex life cycles in order to achieve a correct understanding of these shifts." 15499. Soares, J.A.C.; Batista-Silva, V.F.; Boneto, D.D.; Bailly, D.; Abelha, M.C.F.; Oliveira, I.A. (2015): Assemblage of immature Odonata (Insecta, Anisoptera) in streams of the Mato Grosso do Sul State: spatial and temporal implications. *Iheringia Série Zoologia* 105(3): 325-332. (in English, with Portuguese summary) ["This study investigated the spatial and temporal distribution of Odonata, Anisoptera assemblages in two streams of the Iguatemi River basin, Água Boa and Perobão, which are under strong anthropogenic pressure. Samplings were carried out in both streams during the rainy (March to December 2008) and dry (June and September 2008) periods. The Mantel test was used to check the influence of spatial autocorrelation on the Odonata composition. Spatial and temporal variations in the composition were summarized by the Principal Coordinates Analysis (PCoA), using Mantel test residuals. Odonata assemblages were further evaluated for abundance, richness, diversity and evenness. The most representative genera in each stream and hydrological period were identified by the Indicator Value Method. The spatial-temporal variations in the attributes of the assemblages were assessed using two-factor analysis of variance. We collected 500 immature individuals of 23 genera and three families. Only the composition and abundance showed significant spatial differences, with the highest mean abundance found in the Perobão Stream. As for the temporal variation, abundance, richness and diversity were significantly higher in the dry period for the two streams. Miathyria and Zenithoptera, were the indicator genera of the Água Boa Stream and *Erythrodiplax*, *Libellula*, *Macrothemis*, *Progomphus* and *Tramea*, were the indicator genera of the Perobão Stream. The Odonata fauna was mainly influenced by the temporal dynamics of the rainfall regime, and the composition responded only to spatial variations represented by the streams." 15501. Souza, A.M.; Fogaça, F.N.O.; Cunico, A.M.; Higuti, J. (2015): Does the habitat structure control the distribution

and diversity of the Odonatofauna? *Brazilian Journal of Biology* 75(3): 598-606. (in English, with Portuguese summary) ["The statement that the habitat complexity and structure govern the abundance and diversity of biological communities has been widely investigated. In this context, we assumed the hypothesis of habitat heterogeneity, that is, the higher habitat complexity leads to greater diversity of Odonata. In addition, we analyzed the influence of habitat structure on the distribution of this community, and evaluated the effects of abiotic variables. Odonata larvae were collected with sieves and by electrofishing in ten Neotropical streams belonging to the Pirapó River basin. Forty species of Odonata were registered, which were distributed in eight families, Libellulidae stood out with the highest richness. The high gamma diversity and distribution of Odonata were associated with habitat heterogeneity in these streams. However, the abiotic variables also seem to affect the distribution of Odonata species, in view of the impact of the land use in the vicinity of streams." 15502. Staats, E.G. (2015): Emergent non-consumptive predator effects alter habitat colonization by dipteran prey. MSc thesis, Virginia Commonwealth University, Richmond, Virginia: IV + 22 pp. (in English) ["When ovipositing, prey organisms avoid habitat patches containing predator cues because predators consume, and negatively affect the fitness of their prey. Richness of predator species often enhances the strength of consumptive predator effects, but little is known about how multiple predators combined affect prey non-consumptively. We quantified dipteran colonization in aquatic mesocosms in response to varied predator richness. Multiple predator species combined reduced oviposition by *Culex* mosquitoes, chironomid midges, and the general colonizing dipteran community more than predicted by the effects of the independent predator species. Previous research which quantifies effects of multiple predators on prey as prey abundance, but does not measure consumption by predators, may be underestimating or overestimating the strength of effect by assuming equal colonization. Our findings enhance understanding of the ways predators influence abundances and distributions of their prey, and yields insight into the ways predators may non-consumptively affect prey by changing prey behaviour. Oviposition by the dipteran community was reduced 37% by *Celithemis eponina* ($Z = 3.037$, $df = 18$, $P = 0.0024$), 31% by *Enallagma* spp. ($Z = 2.570$, $df = 18$, $P = 0.0102$), and 27% by crayfish ($Z = -2.189$, $df = 18$, $P = 0.0286$), relative to the predator-free control." avian fauna. Springer New York: 379-451. (in English) ["Prague, which is the capital of the Czech Republic, occupies 496 km² and has a population of 1.2 million people. This chapter describes six of the major invertebrate groups that occur in the city: Arachnida (spiders and related species)—504 species or 58 % of the national species; Coleoptera—Carabidae (ground beetles)—362 species found between 1790 and 2013 or 70 % of the national list of ground beetles; Lepidoptera (diurnal butterflies)—119 species or c. 74 % of the 161 species recorded in the country; Mollusca (molluscs)—146 species or 65 % of the national species; Odonata (dragonflies and damselflies) 41 species or > 50 % of the national species; and Orthoptera (grasshoppers and crickets)—44 species or 53 % of the national species. Prague is one of the European cities where mollusc fauna has been studied in detail. Altogether, 146 species of gastropods and bivalves were recorded here, which is 60 % of the Czech Republic's mollusc fauna. This surprisingly high species diversity reflects the geological and geomorphological diversity of the city that is crucial for molluscs. The gradient from eusynanthropic species over common assemblages of catholic species to the scattered network of nature reserves inhabited by rare and protected species is described. The highest concentration of non-native mollusc species in the Czech Republic was recorded only in Prague." 15505. Stigge, H.A.; Bolek, M.G. (2015): The alteration of life history traits and increased success of *Halipegus eccentricus* through the use of a paratenic host: A comparative study. *Journal of Parasitology* 101(6): 658-665. (in English) [Oklahoma, USA; "Complex life cycles are a hallmark characteristic of many parasites; however, little is known about the process by which life cycles become more complex

through the addition of hosts. Paratenic hosts are present in the life cycles of several phylogenetically distinct groups of helminths; this suggests that they may play a key role during this process. This study examined the development of metacercariae of *Halipegus eccentricus* within intermediate microcrustacean and odonate (*Ischnura* sp.) paratenic hosts. Then a comparative approach was used to evaluate how life history traits of *H. eccentricus* within the anuran definitive hosts differ between metacercariae of the same age that developed within an intermediate ostracod host or a paratenic odonate host. The results of this study indicate that metacercariae of *H. eccentricus* do not grow at the same rate in different intermediate hosts, and significant differences exist in growth within intermediate and paratenic hosts. Individuals from odonate paratenic hosts always had larger bodies and suckers than those of metacercariae of the same age that develop within microcrustacean intermediate hosts. Furthermore, metacercariae from odonates were more successful in establishing and migrating in definitive anuran hosts. Last, individuals from paratenic hosts began reproducing earlier within anuran definitive hosts than age-matched worms that develop within the intermediate hosts. Collectively these results suggest that the variation in body and sucker sizes within odonate and microcrustacean hosts may carry over to the definitive host and in the case of *H. eccentricus* using the paratenic host increases transmission and alters other life history traits within definitive hosts. These results indicate that using a paratenic host can affect the success of parasites in subsequent hosts, and therefore these hosts may provide benefits other than just increasing transmission by bridging an ecological gap." 15506. Stoks, R.; Debecker, S.; Dinh Van, K.; Janssens, L. (2015): Integrating ecology and evolution in aquatic toxicology: insights from damselflies. *Freshwater Science* 34(3): 1032-1039. (in English) ["Current legislation and ecological risk assessment fails to protect aquatic biodiversity at low levels of contaminants. We addressed 3 topics embedded in general stress ecology and evolutionary ecology that are relevant to arrive at a better evaluation of the risk of low contaminant levels in aquatic systems: 1) delayed effects of contaminants, 2) interactions between contaminants and biotic interactors, and 3) vulnerability to contaminants under global warming. We developed these topics by capitalizing on the key insights obtained using damselflies as model organisms. First, delayed contaminant effects on important fitness-related effects exist during the larval stage and after metamorphosis in the adult stage. Second, synergistic interactions of contaminants with bacteria and predation risk have been demonstrated, and we present advances in the mechanistic understanding of these synergisms with biotic interactors. Third, we illustrate the strength of assessing the effect of contaminants under global warming using a space-for-time substitution approach and the need to consider temperature extremes. These studies using damselflies as model organisms highlight the relevance of considering

contaminant effects after the exposure period and in the presence of natural stressors, such as predation risk and higher temperatures. They further highlight the need for spatially explicit risk-assessment and conservation tools. These insights are relevant for most aquatic taxa. Indeed most aquatic taxa have a complex life cycle, are strongly affected by predation risk and by warming, and show latitudinal gradients. Better integration of these topics in ecological risk assessment will be a major challenge for both scientists and policy makers, but of crucial importance to preserve aquatic biodiversity." 15507. Suhling, F.; Suhling, I.; Richter, O. (2015): Temperature response of growth of larval dragonflies – an overview. *International Journal of Odonatology* 18(1): 15-20. (in English) ["We review the knowledge about the thermal reaction norms of larval growth in Odonata with a focus on the temperature response function. We re-analyze literature data and present our own results on growth rates of larvae of 14 species of Libellulidae reared at different temperatures. Temperature response curves (TRC) were fitted in order to estimate two relevant components of the thermal reaction, namely the optimum temperature for growth (T_{opt}) and the increase of growth rate with temperature (Q_{10}). We also examined what is known about the thermal minimum (T_{min}) and the thermal maximum (T_{max}) for growth to delimit the thermal ranges of odonates. All information indicates that larval growth is generally warm adapted, with species-specific variation of T_{opt} of 21–31°C, T_{min} of 8–12°C, and T_{max} of up to 44°C (the latter being the upper lethal limit, the true T_{max} for growth remains unknown). The values of Q_{10} distinguish some more specialized species, mostly with high T_{opt} and of tropical origin, and others being more thermal generalists, often being temperate species and/or from lotic habitats. We examine some biotic and abiotic factors affecting the temperature response of growth and we discuss the temperature response in the light of global warming." (Authors)] Address: Suhling F., Inst. (2015): Genetic signature of the colonisation dynamics along a coastal expansion front in the damselfly *Coenagrion scitulum*. *Ecological Entomology* 40(4): 353-361. (in English) ["1. Many insects are expanding their distribution range polewards as a result of climate change, which has been shown to be associated with founder effects leading to a reduction in genetic diversity and an increase in genetic differentiation. These spatial genetic patterns may arise from colonisation from a broad expansion front or a limited neighbourhood after a stepping stone model of dispersal. The temporal persistence of such founder effects are poorly understood, mainly because studies looking at the fine-scale initial temporal dynamics of the genetic signature of a range expansion are rare. 2. Us-

ing microsatellite markers, we performed a detailed spatio-temporal genetic analysis of the range expanding damselfly *Coenagrion scitulum* (Rambur) along a coastal axis during the first years after colonisation. 3. A decrease was in (private) allelic richness when going northwards along the coastline, which is consistent with a scenario of cumulative founder events. In spite of the spatiotemporal dynamics in the observation records of the species along the coastline, the spatial genetic data indicated a major contribution from the broad expansion front during the colonisation of the coastline rather than a stepping-stone colonisation process. 4. The fine-scale temporal dynamics of the range expansion indicated the absence of persistent founder effects and instead showed considerable temporal instability in genetic indices at the more northern edge populations. This may be explained by genetic immigration and admixture from the broad expansion front in this active disperser." (Authors)] Address: Swaegers, J., Deberiotstr. 32, 3000 Leuven, Belgium. 15509. Swaegers, J.; Mergeay, J.; Van Geystelen, A.; Thery, L.; Larmuseau, M.; Stoks, R. (2015): Neutral and adaptive genomic signatures of rapid poleward range expansion. *Molecular Ecology* 24(24): 6163-6176. (in English) ["Many species are expanding their range polewards and this has been associated with rapid phenotypic change. Yet, it is unclear to what extent this reflects rapid genetic adaptation or neutral processes associated with range expansion, or selection linked to the new thermal conditions encountered. To disentangle these alternatives, we studied the genomic signature of range expansion in the damselfly *Coenagrion scitulum* using 4950 newly developed genomic SNPs and linked this to the rapidly evolved phenotypic differences between core and (newly established) edge populations. Most edge populations were genetically clearly differentiated from the core populations and all were differentiated from each other indicating independent range expansion events. In addition, evidence for genetic drift in the edge populations, and strong evidence for adaptive genetic variation in association with the range expansion was detected. We identified one SNP under consistent selection in four of the five edge populations and showed that the allele increasing in frequency is associated with increased flight performance. This indicates collateral, non-neutral evolutionary changes in independent edge populations driven by the range expansion process. We also detected a genomic signature of adaptation to the newly encountered thermal regimes, reflecting a pattern of countergradient variation. The latter signature was identified at a single SNP as well as in a set of covarying SNPs using a polygenic multilocus approach to detect selection. Overall, this study highlights how a strategic geographic sampling design and the integration of genomic, phenotypic and environmental data can identify and disentangle the neutral and adaptive processes that are simultaneously operating during range expansions." 15510. Tabugo, S. R.; Casas, P.A.; Pareño, M.T.; Peñaredondo, M.A. (2015): Fluctuating asymmetry and developmental instability in the wings of *Neurothemis terminata* as bioindicator of stress. *Advances in Environmental Biology* 9(19): 10-17. (in English) [Background: Fluctuating asymmetry (FA) is a measure of differences between the right and the left half of bilaterally symmetrical organisms and is a useful trait to monitor developmental instability and ecological stress. Dragonflies are often used for biomonitoring purposes. In this study, analysis was done on eurytopic species *Neurothemis terminata*, since they are widely distributed and adapted to different environment. Analysis was based on the Procrustes method and makes comparison of FA indices of homologous points. Using landmark method for shape asymmetry, anatomical landmarks were used and analyzed using Symmetry and Asymmetry in Geometric Data (SAGE) program. Twenty-nine landmarks on the forewing and thirty five landmarks on the hind wing were tested for samples for all populations. Objective: This study assessed developmental stability in three populations of *Neurothemis terminata* using FA analysis on wings from different barangays (Tibanga, Tominobo and Tipanoy) in Iligan City, Mindanao, Philippines. Results: Procrustes ANOVA results showed variation and significant evidence of FA for all populations with relatively high FA for Tibanga population and no indication of Directional asymmetry (DA). Possible explanation for significant FA for populations mean varying level of stress as experienced by populations, suggesting that there is a significant variation between the left and right side of each individual induced by the genes and the environment. Conclusion: Significant FA and increase FA present inability of species to buffer stress in its developmental pathways hence, would mean developmental instability and have implications on species fitness, adaptation, quality of individuals and the level of endogenous and exogenous stress experienced by individuals or populations during development.] Address: Tabugo, Sharon, Dept Biol. Sciences, Mindanao State Univ. - Iligan Institute of Techonlogy, Iligan City, Philippines. E-mail: sharonrose0297@gmail.com

15511. Tajima, Y. (2015): Evolution of sperm displacement mechanism and genital morphology in the damselfly, *Ischnura asiatica*. Dissertation, Graduate School of Life and Environmental Sciences, the University of Tsukuba, Japan: 32 pp. (in English) ["In most species of Odonata, males physically displace rivals' sperm stored in the female sperm storage organs. During copulation, appendages on the male secondary genitalia enter the female sperm storage organs, and trap and remove sperm masses from previous matings. Considerable variations of male and female genitalia among species has been clarified, indicating that males of some species are able to displace all sperm in female sperm storage organs, while males of other species displace not all sperm stored in female sperm storage organs. The *Ischnura asiatica* male has a pair of appendages at the tip of his genitalia that are shorter than the length of the narrow duct from the bursa copulatrix to the spermatheca in the female. Although the males remove bursal sperm during the copulation, the males have no appendages that can remove

spermathecal sperm directly. However, reduction of the number of spermatozoa occurs both in the bursa copulatrix and in the spermatheca during copulation. An alternative mechanism for the reduction of the spermathecal sperm by the male was previously suggested. Females have mechano-receptive sensilla that communicate the presence of an egg to the muscles covering the sperm storage organs for the purpose of fertilization. Then, it is hypothesized that the penis head might mimic the movement of the egg, thus stimulating the sensilla to induce spermathecal sperm ejection by the female. In the present study, in order to clarify the mechanism of sperm removal by stimulating females' sensory system, an interrupted copulation experiment was conducted in the fields in order to examine the relationship between sperm reduction and the morphology of the male's genitalia. The extent of sperm reduction in the spermatheca increased with the width of the penis head. Thus, the hypothesis of the indirect sperm removal mechanism by stimulating females' sensory system was supported. The females might suffer costs such as a loss of genetic variety of their offspring when the sperm displacement is complete. Thus, a counter-adaptation might have evolved in the females to prevent complete sperm displacement. In order to clarify females' adaptation for spermathecal sperm removal, the inter-population and seasonal variation of morphological factors affecting sperm removal, such as the width of the penis head and the number of vaginal sensilla, were examined, and counter-adaptations with which to prevent sperm ejection such as a decrease in the number of vaginal sensilla and an increase in the size of the spermatheca were found in females. Thus, the genital morphology of females and the indirect sperm removal mechanism that makes use of females' sensory system in the reproductive organs were shaped by sexual conflict. Proposing this co-evolutionary scenario for male-female genitalia in *I. asiatica* made it possible to reveal the role of females in genital coevolution." (Author)] Address: not stated

15512. Takahashi, Y. (2015): Mechanisms and tests for geographic clines in genetic polymorphisms. *Population Ecology* 57(2): 355-362. (in English) ["A continuous spatial gradient in visible traits, which is called a cline, is a natural model system for quantifying the effects of selection and stochastic factors and their relative importance. Geographic clines in phenotypic traits also provide key insights into the evolutionary forces that lead to allopatric speciation in nature. Thus, the underlying mechanisms for establishing clines and their evolutionary consequences remain key topics in evolutionary biology. However, few experimental studies have confirmed the underlying mechanisms of geographic clines in morph/allele frequencies, probably because of the lack of understanding of the theoretical basis of geographic clines in polymorphisms and/or suitable comprehensive tests. Thus, I present a general review of the underlying mechanisms for establishing geographic clines in polymorphisms. I also provide a case study using the female dimorphic damselfly *Ischnura senegalensis* to illustrate a strategy that confirms the underlying mechanisms of geographic clines in morph frequencies. This review may

help to address geographic clines in other polymorphic systems, as well as contribute to a comprehensive understanding of geographic clines in quantitative traits, and thus, their evolutionary consequences in nature." 15514. Tamm, J. (2015): Zur Verbreitung und Ökologie von *Cordulegaster bidentata* in Nordhessen mit besonderer Berücksichtigung ihrer Vorkommen auf Buntsandstein (Odonata: Cordulegastridae). *Libellula* 34(1/2): 27-58. (in German, with English summary) ["On distribution and ecology of *Cordulegaster bidentata* in Northern Hesse, Germany, with emphasis on its occurrence on Bunter Sandstone (Odonata: Cordulegastridae) – The distribution of *C. bidentata* (imagines) has been mapped in eight mountain areas of northern Hesse and in parts of the Rhön Mountains in Thüringen, Germany. It is evident that the species occurs very patchily within some of the geological formations studied. *C. bidentata* was rare in the Bunter sandstone areas mainly mapped, but quite common in adjacent Bunter sandstone areas mapped in former studies. Analysis shows that the species' rarity mainly is the result of both the most important natural habitat structures and man-made impact. The main factors are insufficient slope inclines and long stream drainages, and on the other hand, coniferous plantations and ponds dammed close to the springs. But it was remarkable that even habitats suitable for *C. bidentata* were in many cases not populated by the species. This suggests

that the subpopulations recently may live too far from each other to be able to regenerate locally extinct subpopulations from outside. The species is also distributed patchily on palaeozoic greywacke and limestone. Here again both natural and man-made factors are responsible. *C. bidentata* has not been found in the high Rhön and Rothaar mountains. This suggests that there are climate effects as well, like rainy cool summers or freezing of spring outflows in times of severe frost without snow cover. At least in Hesse, *C. bidentata* should be classified as "highly endangered species" because of its regional rarity and several negative impacts which are strong and increasing." 15517. Termaat, T.; van Grunsven, R.A.H.; Plate, C.L.; van Strien, A.J. (2015): Strong recovery of dragonflies in recent decades in The Netherlands. *Freshwater Science* 34(3): 1094-1104. (in English) ["Many dragonfly species in The Netherlands declined in the 20th century because of acidification, eutrophication, and desiccation of lotic and lentic habitats and canalization of streams and rivers. These pressures peaked in the 1970s, when 26 of 65 native species had an unfavourable conservation status on the 1997 Dutch Red List. Since the 1980s, environmental regulations have led to improved water quality, and many habitat restoration

projects have been carried out. We used standardized monitoring data (1999-2013) and unstandardized observations (1991-2013) to investigate how dragonflies have changed in the last 20 y on a national scale. We compared trends of dragonfly species from different habitat types and with southern vs northern distribution in Europe. Dragonflies recovered strongly in The Netherlands in a period of ~20 y, probably because of recent habitat improvements. Lotic species have benefitted more than lentic species, and southern species have more positive trends than northern species, suggesting that climate change has contributed to the recovery. Dragonflies were resilient and able to quickly recover when their habitats were restored. Recovery has led to a better conservation status for many species. Unstandardized data delivered results consistent with those from monitoring data and had greater statistical power to detect trends because many more unstandardized data than standardized data were available. Thus, when the goal is to provide a general overview of changes in dragonflies, unstandardized data can outperform standardized abundance data. However, abundance data may deliver complementary information for individual species. Our results support the suitability of dragonflies as indicators of freshwater habitat condition, but they recover more strongly in The Netherlands than many other insects, possibly because of their higher dispersal abilities or different habitat requirements." (Authors)] Address: Termaat, T., Rijnsteeg 8-10a, 6708 PP Wageningen, The Netherlands. E-mail: tim.termaat@vlinderstichting.nl

15518. Theischinger, G.; Richards, S.J. (2015): The genus *Nososticta* Hagen (Odonata: Platynemididae) from the Papuan region with descriptions of ten new species group taxa. *Odonatologica* 44(1/2): 153-224. (in English) ["The males and, when available, females of ten new species and subspecies of *Nososticta* are described from the Papuan region. They are: *Nososticta caerulea* sp. nov. (♂ holotype: Papua New Guinea, Upper Sepik Basin, 09-vi-2010, ♀ described), *Nososticta finisterrae satisbona* ssp. nov. (♂ holotype: Papua New Guinea, Goodenough Island, 26-X-1953), *Nososticta interrupta* sp. nov. (♂ holotype: Indonesia, Papua Province, Kabupaten Asmat, Vriendschap R., 21-25-vii-2009), *Nososticta kaizei* sp. nov. (♂ holotype: Indonesia, Papua Province, Yapen Island, Ambaidiru village, 15-vii-2006, female described), *Nososticta azurosignata* sp. nov. (♂ holotype: Papua New Guinea, Survey Site 2, Sepik Basin, 25-ii-2010), *Nososticta longicauda* (male holotype: Papua New Guinea, Darai Plateau, 24-vii-2003), *Nososticta manuscola* sp. nov. (♂ holotype: Papua New Guinea, Manus Island, 23-ix-2011, female described), *Nososticta parafonticola* sp. nov. (♂ holotype: Papua New Guinea, Upper Sepik Basin, 10-ii-xii-2009, female described), *Nososticta tricolorata* sp. nov. (♂ holotype: Papua New Guinea, Upper Sepik Basin, 01-xii-2009) and *N. truncata* sp. nov. (♂ holotype: Papua New Guinea, Ivimka camp, Lakekamu, 15-xi-1996). In addition females of *N. africana* Schmidt, 1944, *N. aurantiaca* (Lieftinck, 1938) and *N. hiroakii* Sasamoto, 2007 are described and the morphology and variability of a number of additional species is discussed. Diagnostic charac-

ters of the available genders are illustrated, habitat conditions are given and their affinities are discussed. Live photos of selected species are presented. Keys to the males of all *Nososticta* species known from New Guinea and the Solomon Islands, and to the described females from this region are included. *Nososticta lorentzi* Lieftinck, 1938 is considered a synonym of *N. nigrifrons* (Ris, 1913) (syn. nov.)." 15520. Therry, L., Bonte, D., Stoks, R. (2015): Higher investment in flight morphology does not trade off with fecundity estimates in a poleward range-expanding damselfly. *Ecological Entomology* 40(2): 133-142. (in English) ["(1.) Evolutionary increases in dispersal-related traits are frequently documented during range expansions. Investment in flight-related traits is energetically costly and a trade-off with fecundity may be expected during range expansion. (2.) However, in contrast to wing-dimorphic species, this trade-off is not general in wing-monomorphic species. In the absence of a dispersal-fecundity trade-off, an increased investment in clutch size at the expansion front is expected possibly at a cost of reduced offspring size. (3.) The study evaluated investment in female flight morphology and fecundity-related traits (clutch size, hatchling size) and potential trade-offs among these traits in replicated populations of the poleward range-expanding damselfly *Coenagrion scitulum*. (4.) Females at the expansion front had a higher relative thorax length, indicating an increased investment in flight; this can be explained by spatial sorting of dispersal ability or in situ natural selection at the expansion front. Edge females produced larger hatchlings, however, this pattern was totally driven by the population-specific thermal larval regimes and could not be attributed to the range expansion per se. By contrast, clutch sizes did not differ between core and edge populations. There was no signal of a dispersal-fecundity trade-off either for a trade-off between clutch size and hatchling size. (5.) These results indicate that evolution of a higher dispersal ability at the expansion front of *C. scitulum* does not trade off with investment in fecundity, hence a dispersal-fecundity trade-off is unlikely to

slow down range expansion of this species." (Authors)] Address: Therry, L., Laboratory of Aquatic Ecology, Evolution and Conservation, KU Leuven, Deberiotstraat 32, 3000 Leuven, Belgium. E-mail: Lieven.Therry@bio.kuleuven.be

15521. Tichanek, F.; Tropek, R. (2015): Conservation value of post-mining headwaters: drainage channels at a lignite spoil heap harbour threatened stream dragonflies. *Journal of Insect Conservation* 19: 975-985. (in English) ["Headwaters and small streams are crucial components of riverine systems, harbouring many highly specialized and unique invertebrate species. Unfortunately, the overwhelming majority of the Central European lowland headwaters are channelized, eutrophicated and/or polluted, and many related species have become critically endangered. Artificial streams established to drain some post-mining sites supplement a network of headwaters and generally do not suffer from agricultural pollution. Nevertheless, the biodiversity and conservation potential of the streams at post-mining sites has never been evaluated. We studied the biodiversity of Odonata at 53 sections (30 m) of an extraordinarily dense system of drainage ditches at a large lignite spoil heap in the Czech Republic. We recorded 22 dragonfly species, of which eight are threatened according to the national Red List. Moreover, four of them are closely associated with the endangered environment of small streams. Overall diversity was generally low at very tiny and/or narrowed streams and was also strongly reduced by high water velocity, high bankside inclination and dominance of expansive common reeds. Sufficient cover of rather shallow sediment layers strongly supports the studied diversity indicators. We thus conclude that post-mining streams in drainage ditches could have a strong potential to offer secondary habitats for threatened headwater biodiversity. However, intermittent reed suppression and the establishment of gently sloping banks and a structured stream bottom are necessary measures for maximizing post-mining stream conservation." (2015): Fourier transform infrared spectroscopy and imaging of dragonfly, damselfly and cicada wing membranes. *Spectroscopy Europe* 27(4): 15-18. (in English) ["Conclusion: Insect wings possess some remarkable properties, enabling them to thrive in challenging environments. Often, a combination of nano- and micro-structured topography, with chemical heterogeneity on the micron scale, provides these structures with efficient superhydrophobic, self-cleaning and antibacterial capabilities. Their complex surfaces are providing inspiration for the design of novel coatings and surface structures that can mimic these beneficial properties. High spatial resolution FT-IR spectroscopy and imaging, when combined with other techniques such as SEM and GC-MS, provide unique insights into the complex

chemical patterning that contributes to this functionality. Further developments in FT-IR imaging, such as 3D infrared tomography and scanning near-field nano spectroscopy have the potential to add a further dimension to the chemical and physical information that is enabling us to obtain a greater understanding of these natural surfaces. These techniques can also continue to be applied to the study of manmade material surfaces that attempt to emulate the properties of their biological templates." 15523. Tong, J.; Chang, Z.; Yang, X.; Zhang, J.; Liu, X.; Chetwynd, D.G.; Chen, D.; Sun, J. (2015): Nanoindentation mechanical properties and structural biomimetic models of three species of insects wings. *Journal of Wuhan University of Technology-Mater. Sci. Ed.* 30(4): 831-839. (in English) ["Mimicking insect flights were used to design and develop new engineering materials. Although extensive research was done to study various aspects of flying insects. Because the detailed mechanics and underlying principles involved in insect flights remain largely unknown. A systematic study was carried on insect flights by using a combination of several advanced techniques to develop new models for the simulation and analysis of the wing membrane and veins of three types of insect wings, namely dragonfly (*Pantala flavescens* Fabricius), honeybee (*Apis cerana cerana* Fabricius) and fly (*Sarcophaga carnaria* Linnaeus). In order to gain insights into the flight mechanics of insects, reverse engineering methods were used to establish three-dimensional geometrical models of the membranous wings, so we can make a comparative analysis. Then nano-mechanical test of the three insect wing membranes was performed to provide experimental parameter values for mechanical models in terms of nano-hardness and elastic modulus. Finally, a computational model was established by using the finite element analysis (ANSYS) to analyze and compare the wings under a variety of simplified load regimes that are concentrated force, uniform line-load and a torque. This work opened up the possibility towards developing an engineering basis for the biomimetic design of thin solid films and 2D advanced engineering composite materials." 15524. Torres-Cambas, Y.; Lorenzo-Carballa, M.O.; Ferreira, S.; Cordero-Rivera, A. (2015): *Hypolestes hatuey* sp. nov.: a new species of the enigmatic genus *Hypolestes* (Odonata, Hypolestidae) from Hispaniola. *Zootaxa* 4000(2): 207-226. (in English) ["Both sexes of *Hypolestes hatuey* Torres-Cambas, sp. nov. (Odonata: Zygoptera: Hypolestidae) from Hispaniola are described and illustrated here. This newly described species differs from *H. trinitatis* and *H. clara*, the other two species within the genus, by the morphology of the genital ligula and male cerci. Females of *H.*

hatuey sp. nov. differ from *H. clara* by the shape of the female antehumeral stripe and wing venation. Morphological distinctiveness in males is supported by genetic differences in the 16S mitochondrial gene. Following the categories and criteria of the IUCN Red List of Threatened Species, we suggest this species should be listed as Data Deficient (DD), given that available data on its distribution are too limited to assess its risk of extinction." (Authors)] Address: Torres-Cambas, Y., Depto Biol., Fac. Cien. Nat., Univ. de Oriente. Patricio Lumumba s/n, Santiago de Cuba, Cuba. E-mail: ytorres@cnt.uo.edu.cu, yusdiel.torres@gmail.com

15525. Torres-Cambas, Y.; Trapero-Quintana, A.D.; Lorenzo-Carballa, M.O.; Newell, D.; Suriel, C.; Cordero-Rivera, A. (2015): An update on the distribution of threatened odonate species from the Greater Antilles. *International Journal of Odonatology* 18(2): 89-104. (in English) ["The Antilles harbour several island endemic odonate species, including some palaeoendemics, within a relatively small and anthropized area. Such attributes give this archipelago a special significance for the conservation of Odonata in the Neotropics. However, despite the importance of these islands, inadequately surveyed regions persist, mainly in the Greater Antilles, and there is not enough information to set IUCN threat categories for eight species supposed to be at risk, which are currently classified as data deficient (DD). To update the distribution of endangered (EN), vulnerable (VU) and DD species, we conducted a series of field surveys in Dominican Republic, Jamaica and Cuba, and compiled data from literature, museum collections as well as personal communications. We sampled a total of 37 species, including *Microneura caligata*, *Phyllestes ethelae* and *Hypolestes clara* (EN); *H. trinitatis* (VU); and *Diceratobasis macrogaster*, *Neoneura maria* and *Protoneura capillaris* (DD). We provide new locality records for *M. caligata*, *N. carnatica* (DD), *N. maria* (DD), *P. capillaris*, *H. clara*, *H. trinitatis* and *Erythrodiplax bromeliicola* (DD). According to our results, we suggest changing the category of *D. macrogaster*, *D. melanogaster*, *N. carnatica*, *N. maria* and *P. capillaris* to VU." 15527. Toth, Z. (2015): Context-dependent plastic response during egg-laying in a widespread newt species. *PLoS ONE*

10(8): e0136044. doi:10.1371/journal.pone.0136044: 18 pp. (in English) ["Previous research on predator-induced phenotypic plasticity mostly focused on responses in morphology, developmental time and/or behaviour during early life stages, but the potential significance of anticipatory parental responses has been investigated less often. In this study I examined behavioural and maternal responses of gravid female smooth newts, *Lissotriton vulgaris*, in the presence of chemical cues originating from invertebrate predators, *Acilius sulcatus* water beetles and *Aeshna cyanea* dragonfly larvae. More specifically, I tested the extent of oviposition preference, plasticity in egg-wrapping behaviour and plasticity in egg size when females had the possibility to lay eggs at oviposition sites with and without predator cues during overnight trials. I found that individuals did not avoid laying eggs in the environment with predator cues; however, individuals that deposited eggs into both environments adjusted the size of the laid eggs to the perceived environment. Females deposited larger eggs earlier in the season but egg size decreased with time in the absence of predator cues, whereas individuals laid eggs of average size throughout the investigated reproductive period when such cues were present. Also, egg size was found to be positively related to hatching success. Individuals did not adjust their wrapping behaviour to the presence of predator cues, but females differed in the extent of egg-wrapping between ponds. Females' body mass and tail depth were also different between ponds, whereas their body size was positively associated with egg size. According to these results, female smooth newts have the potential to exhibit activational plasticity and invest differently into eggs depending on temporal and environmental factors. Such an anticipatory response may contribute to the success of this caudate species under a wide range of predator regimes at its natural breeding habitats." 15528. Touchon, J.C.; Vonesh, J.R. (2015): Variation in abundance and efficacy of tadpole predators in a Neotropical pond community. *Journal of Herpetology* 50(1): 113-119. (in English, with Spanish summary) ["Variation in predation risk plays an important role in shaping prey behaviour, morphology, life history, population dynamics, and community structure in freshwater systems. Anuran larvae are important prey in freshwater communities and spatiotemporal variation in risk can arise from changes in the number and identity of predators; however, our understanding of variation in abundance, identity, and foraging rates for natural predator assemblages in tropical pond communities is limited. We surveyed ponds near Gamboa, Panama in 2004 and 2010 to estimate variation in predator communities of tadpoles over space and time. We also conducted short-term predation trials with the 10 most common predators using hatchling tadpoles of two widespread Neotropical frog species, Red-Eyed Treefrogs (*Agalychnis callidryas*) and Pantless Treefrogs (*Dendropsophus ebraccatus*). Predator abundance varied nearly threefold across ponds within a single year and as much as 19-fold within a pond across

years. Dominant taxa also varied, with backswimmers (Notonectidae), poeciliid fish, or libellulid dragonfly naiads being the most common depending upon pond and year. Predation trials revealed that prey-specific predation rates differed among predator taxa. Some presumed predators did not consume hatchlings, whereas others consumed >90% of prey. The smaller *D. ebraccatus* hatchlings generally experienced higher predation rates; however, large invertebrate predators like aeshnid dragonfly naiads, giant water bugs, and fishing spiders consumed more *A. callidryas*. These results suggest that strong but variable larval-stage risk may be an important selective factor shaping tadpole communities and phenotypes in Neotropical ponds." 15529. Trockur, B.; Lingenfelder, U. (2015): Die FFH-Libellenarten im Saarland (Insecta: Odonata). *Abh. DELATTINIA* 40: 77-136. (in German, with English and French summaries) ["There are four dragonfly species in the Saarland listed in annex II and/or IV of the EU Habitats Directive. An overall view for each of the species is given concerning distribution and status, based on new data from the years 2012 until 2014. Changes in population size and threatening factors for the species and their occurrence are discussed. The situation for *Coenagrion mercuriale* is critical. Actually only three populations are known, all with low abundances. Both populations in the floodplain of the river Blies are severely threatened by intensive use and inappropriate measures of preservation applied. The third population of the species near Heinitz seems to be stable, but the core of the population depends on right preservation and is therefore indirectly and latently endangered. *Ophiogomphus cecilia* occurs especially in the southeast of the Saarland and clearly shows positive trends. The river Blies is the most important locality for recording. It contains in the meantime a stable population. But the situation at other actual or former localities is not clear. The number of localities of *Leucorrhinia caudalis* is more or less almost constantly increasing in the last years, and thus a positive trend can be attested. The species has an abundant and stable population near Heinitz with increasing abundance, while all other localities in the Saarland show instable conditions in population size. Trends are even negative in some places. *Leucorrhinia pectoralis* has been recorded only twice in the Saarland in 2012 and 2014 and is of unclear status here. Conservation measures for *C. mercuriale* are absolutely required at present to preserve, protect and/or support the populations, and they would be for *Leucorrhinia caudalis* at least in some localities helpful. Species specific requirements on the habitat have to be respected for *O. cecilia* also because of actual or potential threats not only in the areas of the Habitats Directive." 15530. Troyer, R.R.; Turner, A.M. (2015): Chemosensory perception of predators by larval amphibians depends on water quality. *PLoS ONE* 10(6): e0131516. doi:10.1371/

journal.pone.0131516: 10 pp. (in English) ["The acquisition of sensory information by animals is central to species interactions. In aquatic environments, most taxa use chemical cues to assess predation risk and other key ecological factors. A number of laboratory studies suggest that anthropogenic pollutants can disrupt chemoreception, even when at low, non-toxic concentrations, but there are few tests of whether real-world variation in water quality affects chemoreception. Here we investigate whether chemosensory perception of predators (*Anax* sp.) by the gray treefrog, *Hyla versicolor*, depends on water quality. We evaluated the anti-predator response of anuran tadpoles housed in water collected from three sites that represent strong contrasts in the concentration and types of dissolved solids: de-chlorinated tap water, water from an impaired stream, and treated wastewater effluent. Behavioural assays were conducted in laboratory aquaria. Chemical cues associated with predation were generated by feeding tadpoles to dragonfly predators held in containers, and then transferring aliquots of water from dragonfly containers to experimental aquaria. Tadpoles housed in tap water responded to predator cues with an activity reduction of 49%. Tadpoles housed in stream water and wastewater effluent responded to predator cues by reducing activity by 29% and 24% respectively. The results of factorial ANOVA support the hypothesis that the response to predator cues depended on water type. These results show that alteration of the chemical environment can mediate chemical perception of predators in aquatic ecosystems. Because most aquatic species rely on chemoreception to gather information on the location of food and predators, any impairment of sensory perception likely has important ecological consequences." 15531. Valdivia, F.G.A. (2015): Territoriality of Zenithoptera lanei (Anisoptera: Libellulidae) in an area of Brazilian savana. Master's Dissertation, Faculdade de Filosofia, Ciências e Letras de Ribeirão Preto, Univ. Sao Paulo: V + 53 pp. (in Portuguese, with English summary) ["Animal behaviour associated with morphological characteristics supplies evidence for a better understanding of how sexual behaviour has evolved, and how organisms can maximize their reproductive success. Factors such as size, fat reserves and other sexual characters such as coloration are essential to individual better performance in relation to conspecifics. These factors can bring information of the male quality to other conspecifics and females. This quality keeps relation with the physical condition (energy reserves) that they have which is required to succeed in breeding, as reproduction is one of the most expensive activity in energy cost in relation to other activities. The reproductive behaviour is related to the individual fat reserves that influences, among other factors, in the condition that they adopt and to the duration in time of the related interactions to reproduction. Therefore, individuals with more developed characteristics or with better physical conditions will have an advantage in the reproduction comparing with other individuals of the community. The dragonfly Zenithoptera lanei is a Neotropical species

present in Brazil, only studied so far by Guillermo-Ferreira in 2015, when structures that conform this pruinosity and his function in the intraspecific communication were described. In this study, describe the sexual behaviour of *Z. lanei*. Was hypothesized that in this species males present territorial behaviour, and that the coloration of wings, body size and the energy reserves (fat) may play an important role in territorial condition and reproductive success. Thus, males with higher quantity of energy and larger size should win more disputes, defend territories and, therefore, maintain the territorial condition. In addition, was also assessed whether this condition of territoriality may influence the duration of the copulation and oviposition by females. The results showed that males are territorial, and its territoriality keeps relation with size and the physical condition. In other words, males with larger body and higher energy reserves have won more disputes and maintained a territory. Although males were territorial, there was no difference between the duration of reproductive interactions, winning males and losers, thus indicating that the reproductive interactions are not influenced by the condition of territoriality of the male." 15533. Van Schandevyl, D.; Vercruyssen, W. (2015): Yellow-spotted Emerald (*Somatochlora flavomaculata*) looking for new reproduction sites. *Brachytron* 17(2): 100-106. (in Dutch, with English summary) ["*S. flavomaculata* is a rare species in Belgium. Its distribution is restricted to swampy areas in the eastern part of Flanders and the southernmost part of Wallonia. Sightings of vagrant individuals are exceptional. This article describes the discovery (2013-2014) of the species in East Flanders. Until recently the species was unknown from the western part of Flanders. At the two newly discovered localities (the Wellemers in Denderleeuw and the Damvallei, east of Ghent), a small population may be present. In the Netherlands the range of the Yellow-spotted Emerald has greatly increased in the last ten years

and a number of new populations were discovered. Similarly, an expansion of *S. flavomaculata* can be expected in Belgium." (Authors)] Address: Danny Van Schandevyl. E-mail: danny.van.schandevyl@telenet.be

15534. Vannini, L.; Bowen, J.H.; Reed, T.W.; Willis, J.H. (2015): The CPCFC cuticular protein family: anatomical and cuticular locations in *Anopheles gambiae* and distribution throughout Pancrustacea. *Insect Biochemistry and Molecular Biology* 65: 57-67. (in English) ["Highlights: •New cuticular protein family described, characterized by a 16 amino acid motif ending C-X(5)-C. •In *Anopheles gambiae*, transcripts localized primarily in epidermis underlying hard cuticle. •Proteins localized primarily in endocuticle. •Family members identified in 14 orders of Hexapoda and 4 classes of Crustacea. Abstract: Arthropod cuticles have, in addition to chitin, many structural proteins belonging to diverse families. Information is sparse about how these different cuticular proteins contribute to the cuticle. Most cuticular proteins lack cysteine with the exception of two families (CPAP1 and CPAP3), recently described, and the one other that we now report on that has a motif of 16 amino acids first identified in a protein, Bc-NCP1, from the cuticle of nymphs of the cockroach, *Blaberus craniifer* (Jensen et al., 1997). This motif turns out to be present as two or three copies in one or two proteins in species from many orders of Hexapoda. We have named the family of cuticular proteins with this motif CPCFC, based on its unique feature of having two cysteines interrupted by five amino acids (C-X(5)-C). Analysis of the single member of the family in *Anopheles gambiae* (*AgamCPCFC1*) revealed that its mRNA is most abundant immediately following ecdysis in larvae, pupae and adults. The mRNA is localized primarily in epidermis that secretes hard cuticle, sclerites, setae, head capsules, appendages and spermatheca. EM immunolocalization revealed the presence of the protein, generally in endocuticle of legs and antennae. A phylogenetic analysis found proteins bearing this motif in 14 orders of Hexapoda, but not in some species for which there are complete genomic data. Proteins were much longer in Coleoptera and Diptera than in other orders. In contrast to the 1 and occasionally 2 copies in other species, a dragonfly, *Ladona fulva*, has at least 14 genes coding for family members. CPCFC proteins were present in four classes of Crustacea with 5 repeats in one species, and motifs that ended C-X(7)-C in Malacostraca. They were not detected, except as obvious contaminants, in any other arthropod subphyla or in any other phylum. The conservation of CPCFC proteins throughout the Pancrustacea and the small number of copies in individual species indicate that, when present, these proteins are serving important functions worthy of further study." 15536. Venkatesh, A.; Tyagi, B.K. (2015): *Bradinopyga geminata* (Anisoptera: Libellulidae) as a predator of *Aedes aegypti* immatures (Diptera: Culicidae). *International Journal of Mosquito Research* 2(2): 98-105. (in English) ["Predatory potential of 12th instar larvae of *Bradinopyga geminata* on *Aedes* mosquito immatures was observed, by exposing two different prey-predator combinations (Prey: Predator; 200:1 and 1000:5). One and five 12th instar larvae of *B. geminata* were provided with 200 (SET A) and 1000 (SET B) I, II, III & IV instars of *Aedes aegypti* larvae as prey, for a period of 24 hr in plastic containers containing 1 and 5 litres of water respectively. The number of *Ae. aegypti* larvae consumed by *B. geminata* larvae were noted through one day, at an interval of 3 hours. To maintain the prey density, same number of larvae was replenished. In the daily feeding rate experiment the consumption showed a peak during the 9th hour, irrespective of the instar stages. Predation rate of *B. geminata* was more for I instar. The predatory impact values for I instar in both Set A and B were 4.12 ± 0.05 and 3.6 ± 0.02 respectively, and were significant ($P < 0.01$). The comparative clearance rate for Set A and B was highly significant for the first instar ($P < 0.01$). This study revealed that *B. geminata* larvae is an efficient predator of mosquito larvae. The rate of consumption was dependent on the size of the prey and the density of the predator. The predatory impact of *B. geminata* was more for the first instar *Ae. aegypti*, owing to its size and energy requirements. To conclude, *B. geminata* is an efficient bio-control agent for container breeding *Ae. aegypti* and can be an effective tool in the integrated vector control programme." English) ["Helsinki is located on a peninsula projecting into the Baltic Sea from the south coast of Finland. The country lies in the Boreal region, which is typified by the mixed coniferous forests, although Helsinki itself is located in a narrow strip of the hemiboreal zone, which also has noble deciduous forest, similar to those of the temperate region. The region is also characterized by a variety of wetland habitats. Descriptions are provided of the following invertebrate taxa: Arachnida, Carabidae, Syrphidae, Apidae sensu lato, Formicidae, Isopoda, Lepidoptera and Odonata, as well as some of the habitats they occupy. The information provided is rather patchy, as the amount of data varies considerably between different taxa and habitats. The urban region contains some sites that are valuable for invertebrate diversity, regardless of their location. The characteristic features of the urban environment, such as mild climate and longer growing season, may be beneficial for some taxa." (in English) ["Biomimetic air vehicles (BAV) are a class of unmanned aircraft that mimic the flapping wing kinematics of flying organisms (e.g. birds, bats, and insects [including dragonflies]). Research into BAV has rapidly expanded over the last 30 years. In this paper, we present a comprehensive bibliometric review of engineering and biology journal articles that were published on this subject between 1984 and 2014. These articles are organized into five topical categories: aerodynamics, guidance and control, mechanisms, structures and materials, and system design. All of the articles are compartmented into one of these categories based on their primary focus. Several aspects of these articles are examined: publication year, number of citations, journal, authoring organization and country, non-academic funding sources, and the flying organism focused upon for bio-mimicry. This review provides useful information on the state of the art of BAV research and insight on potential future directions. Our intention is that this will serve as a resource for those already engaged in BAV research and enable insight that promotes further research interest." 15540. Wasscher, M. (2015): Edmond de Selys Longchamps and the study of dragonflies in the Netherlands. *Brachytron* 17(2): 116-125. (in Dutch, with English summary) ["The importance of Selys for the Dutch study of dragonflies is described, using articles, his published diaries and his scientific correspondence present in RBINS (Brussels) and Naturalis (Leiden). Selys visited the RMNH collection (now NCB Naturalis) in Leiden six times and the collection of Natura Artis Magistra in Amsterdam five times. For the RMNH he carried out identifications, they exchanged dragonflies and with some curators he conducted a regular correspondence. The summarizing catalogue which Selys made in 1879 of the RMNH dragonfly collection has unfortunately not yet been found. Selys had a warm friendship with Adrien Maurissen from Maastricht, for whom he wrote a necrology, and with Herman Albarda from Friesland, after whom he named *Sieboldius albardae*. The three publications concerning dragonflies in the Netherlands which appeared in 1852, 1866, and 1889 are clearly influenced by Selys. With that and his regular contact with the RMNH Selys has sown the seeds for the current flourishing study of dragonflies in the Netherlands.] Address: Wasscher, M., Minstraat 15bis, NL-3582 CA Utrecht, The Netherlands, E-mail: marcel.hilair@12move.nl

15541. Watanabe, M. (2015): Larval community dynamics in an artificial habitat created for conservation of a local population of the endangered brackish water damselfly *Mortonagrion hirosei* (Odonata: Coenagrionidae). *Odonatologica* 44(1/2): 45-62. (in English) ["Brackish water ecosystems in estuaries are highly threatened due to land development, the improvement of embankments, and reclamation. Several threatened species of dragonflies and damselflies inhabit these ecosystems. The brackish water damselfly, *M. hirosei*, has been an important focus of conservation studies. Here, we describe a conservation project for *M. hirosei* begun in 2003, and review the data collected in order to quantify details of the species' life cycle, especially larvae and larval environment. An artificially established reed community was created as a habitat for this damselfly, and water depth, salinity, and water temperature in the reed bed were continuously monitored thereafter. Because this damselfly is univoltine, the number and distribution of the odonate larvae in the experimental habitat in May, or presence of last-instar larvae of *M. hirosei*, were considered suitable indices of colonisation success. Since many odonate adults, including *M. hirosei*, visited the habitat in the first year and laid eggs, high larval diversity was found in the second year. Although the salinity of water in the reed bed varied because cyclical tidal fluctuations, the saline water gradually excluded odonate larvae that inhabit freshwater only. However, *M. hirosei* survived, and the larval population increased year by year. Consequently, the odonate larval diversity in the artificial habitat decreased, while the population of *M. hirosei* was maintained." (Author)] Address: Watanabe, M., Dept Biol., Fac. Education, Mie Univ., Tsu, Mie 514-8507, Japan. E-mail: watanabe@edu.mie-u.ac.jp

15543. Wesner, J.S.; Meyers, P.; Billman, E.J.; Belk, M.C. (2015): Habitat selection and consumption across a landscape of multiple predators. *Ecology and Evolution* 5(1): 121-129. (in English) ["Predator community composition can alter habitat quality for prey by changing the strength and direction of consumptive effects. Whether predator community composition also alters prey density via nonconsumptive effects during habitat selection is not well known, but is important for understanding how changes to predator communities will alter prey populations. We tested the hypothesis that predator community composition (presence of caged trout, caged dragonflies [*Ophiogomphus severus*], or caged trout + dragonflies) alters colonization of aquatic mesocosms by ovipositing aquatic insects. In a previous experiment in this system, we found a spatial contagion effect, in which insects avoided pools with predators, but only when predator-free pools were isolated (~5 m away from predator pools). Here, we removed the isolated predator-free pools, allowing us to test whether insects would make fine-scale (~1 m) oviposition decisions in the absence of preferred isolated pools. We also estimated consumptive effects by allowing predators to feed on colonists for 5 days following colonization. All insects collected after 21 days were dipterans, dominated by Chironomidae. Total colonization, measured as the number of developing larvae after 21 days, was not affected by either predator presence or composition. Consumption was significant in the trout only treatment, reducing larval insect density by $46 \pm 37\%$ (mean \pm SE). No other predator treatment significantly reduced prey density, although the proportion of chironomid larvae in protective cases increased in response to direct predation from dragonflies, indicating an antipredatory behavioural response. Taken together, these results reveal that predator community composition altered larval survival and behaviour, but colonizing females either did not or could not assess these risks across small scales during oviposition." 15544. White, E.L.; Hunt, P.D.; Schlesinger, M.D.; Corser, J.D.; deMaynadier, P.G. (2015): Prioritizing Odonata for conservation action in the northeastern USA. *Freshwater Science* 34(3): 1079-1093. (in English) ["Odonata are valuable biological indicators of freshwater ecosystem integrity and climate change, and the northeastern USA (Virginia to Maine) is a hotspot of odonate diversity and a region of historical and growing threats to freshwater ecosystems. This duality highlights the urgency of developing a comprehensive conservation assessment of the region's 228 resident

odonate species. We offer a prioritization framework modified from NatureServe's method for assessing conservation status ranks by assigning a single regional vulnerability metric (R-rank) reflecting each species' degree of relative extinction risk in the northeastern USA. We calculated the R-rank based on 3 rarity factors (range extent, area of occupancy, and habitat specificity), 1 threat factor (vulnerability of occupied habitats), and 1 trend factor (relative change in range size). We combine this R-rank with the degree of endemism (% of the species' USA and Canadian range that falls within the region) as a proxy for regional responsibility, thereby deriving a list of species of combined vulnerability and regional management responsibility. Overall, 18% of the region's odonate fauna is imperiled (R1 and R2), and peatlands, low-gradient streams and seeps, high-gradient headwaters, and larger rivers that harbour a disproportionate number of these species should be considered as priority habitat types for conservation. We anticipate that our analysis might serve as a model for guiding and standardizing conservation assessments at multiple scales for Odonata and other diverse taxa that have not yet received attention to prioritization." (Authors)] Address: White, E.L., New York Natural Heritage Program, State Univ. of New York College of Environmental Science and Forestry, 625 Broadway 5th Floor, Albany, New York 12233-4757 USA

15545. Wildermuth, H.; Roland, H.-J.; Hein, A.T. (2015): Landmilben als Libellenparasiten – bisher bekanntes Wirtsspektrum in Europa (Acari: Prostigmata; Odonata). *Libellula* 34(1/2): 103-115. (in German, with English summary) ["Terrestrial mites as parasites of dragonflies – updated host spectrum in Europe (Acari: Prostigmata; Odonata) – In contrast to aquatic mites as parasites of Odonata few studies of terrestrial mites exist. In order to obtain more information on their distribution and their relation to their odonate hosts, an appeal to odonatologists was made via various photo- and dragonfly platforms on the internet to submit photos of odonates infested by mites. Besides a great amount of images with aquatic mites, 24 photo documents with terrestrial mites came in. Among the host species five have been unknown up to now: *Calopteryx xanthostoma*, *Libellula quadrimaculata*, *Leucorrhinia dubia*, *Sympetrum flaveolum*, and *S. sanguineum*. The parasite load was 1.7 mites per host individual on average. Most mite larvae clung to the host's legs, some also to the abdomen and the thorax, only one to the head. The records of the terrestrial mites originated from eleven localities, most of them from Germany, two from Georgia and one from France. All hitherto published records of terrestrial mites on Odonata are summarized and reviewed. The host spectrum, the distribution in Europe, the prevalence and parasite load as well as the problem of parasitization and/or phoresy of terrestrial mites on Odonata are discussed." (Authors)] Address: Hein, A.T., Ackerstr. 109, 13355 Berlin, Germany. E-mail: post@libellenwissen.de

15546. Williams, A.T. (2015): The dragonflies of Reigersbroek and Schrevenhofsbroekje. The effect of nature development on dragonfly fauna. *Natuurhistorisch maandblad*

104(6): 103-109. (in Dutch, with English summary) ["The natural landscape of Reigersbroek and Schrevenhofsbroekje in the province of Limburg is being redeveloped in order to restore its original marshy character. Topsoil removal, the scattering of wet heathland vegetation clippings and the raising of water levels have created different habitats for dragonflies. This restoration work has led to various inventories being carried out of the flora and fauna in the area, and by extension the monitoring of the dragonfly population. The restoration work has resulted in sparsely-planted shallow pools and ponds in Reigersbroek, which is still in a pioneer phase, and two large ponds with structure-rich banks in Schrevenhofsbroekje. The habitats in Reigersbroek currently appear to attract predominantly pioneer species such as *Ischnura pumilio* and *Sympetrum fonscolombii*, but are also visited by fenland dragonflies and vagrants from southern regions such as *Anax parthenope*. A number of ditches in the area have been colonised by *Orthetrum coerulescens* and *Sympetrum pedemontanum*. Given the growth in species and populations since the beginning of the restoration work, it is expected that the variety and quantities of species will continue to develop as the area evolves into a mature, contiguous wetland reserve with management focused on the on the preservation of present populations.] Address: Williams, A.T., Julianastraat 5, 6067 EV Linne, The Netherlands

15547. Willkommen, J.; Michels, J.; Gorb, S.N. (2015): Functional morphology of the male caudal appendages of the damselfly *Ischnura elegans* (Zygoptera: Coenagrionidae). *Arthropod Structure & Development* 44(4): 289-300. (in English) ["Highlights: The clasping of the dragonfly *Ischnura elegans* represents an energy-efficient process. •The closing of the male claspers is a mainly passive process. •Surface microstructures and the female thoracic morphology secure the clamping. Odonata are usually regarded as one of the most ancient extant lineages of winged insects. Their copulatory apparatus and mating behaviour are unique among insects. Male damselflies use their caudal appendages to clasp the female's prothorax during both copulation and egg-laying and have a secondary copulatory apparatus for sperm transfer. Knowledge of the functional morphology of the male caudal appendages is the basis for understanding the evolution of these structures in Odonata and respective organs in other insects. However, it is still not exactly known how the zygopteran claspers work. In this study, we applied micro-computed tomography and a variety of microscopy techniques to examine the morphology, surface microstructure, cuticle material composition and muscle topography of the male caudal appendages of *Ischnura elegans*. The results indicate that the closing of the paraproctal claspers is mainly passive. This indirect closing mechanism is very likely supported by high proportions of the elastic protein resilin present in the cuticle of the paraproctal bases. In addition, the prothoracic morphology of the female plays an important role in the indirect closing of the male claspers. Our data indicate that both structures – the male claspers and the female prothoracic hump – function together like a snap-fastener." (Authors)] Address:

15548. Worthen, W.B.; Turner, L.H. (2015): The effects of odonate species abundance and diversity on parasitism by water mites (*Arrenurus* spp.): testing the dilution effect. *International Journal of Odonatology* 18(3): 233-248. (in English) ["Water mites (*Arrenurus* spp.) parasitize adult dragonflies. We collected dragonflies weekly at 11 waterbodies in Greenville Co. and Pickens Co., SC, USA, to: (1) compare parasitism prevalence across species, sites, and sampling periods; (2) test the hypothesis that prevalence correlates with host abundance; (3) test the hypothesis that prevalence is inversely related to host diversity (the "dilution effect"); and (4) test the hypothesis that prevalence and intensity vary with ecological conditions. Parasitism prevalence varied among well-sampled ($N > 30$) hosts; *Perithemis tenera*, *Plathemis lydia*, and *Celithemis ornata* had no mites, whereas prevalence exceeded 20% for *Argia fumipennis*, *Celithemis elisa*, and *C. fasciata*. Differences among species, however, varied across sites and through time, suggesting patchy or species-specific relationships not captured by our diffuse analysis at the generic level. Prevalence was positively correlated with species abundance and host site occupancy, as expected for generalist parasites. There was no evidence of a dilution effect: there were no significant negative relationships between prevalence and three measures of species richness (observed richness, extrapolated Sest, or CHAO2 estimated richness), considering all odonate species, parasitized species, or only species in the parasitized families Libellulidae or Coenagrionidae. Odonate communities in more pristine sites had higher mean prevalence (18.4 ± 6.0) and median intensity (4.5) than those in disturbed sites (13.1 ± 7.0 ; 3.0), but only intensities were marginally significantly different. Parasitism by *Arrenurus* spp. met the criteria for a dilution effect, but did not exhibit this effect as a diffuse community-level response." (Authors)] Address: Worthen, W.B., Biology Department, Furman University, Greenville, SC, USA. E-mail: wade.worthen@furman.edu

15549. Yeh, W.-C.; Kiyoshi, T.; Wang, M. (2015): *Sarasaeschna gaofengensis* sp. nov. (Odonata, Aeshnidae), a new dragonfly species described from Yunnan, China. *Bull. Natl. Mus. Nat. Sei., Ser. A*, 41(3): 163-169. (in English) ["*Sarasaeschna gaofengensis* Yeh and Kiyoshi sp. nov. (holotype male, Gaofeng, Yunnan, China) is characterized by razor-like male cerci and widely divaricated epiproct with attenuated apical forks. It possesses a vesica spermalis with flagella adjoining ventral margin of its apical segment and is considered to belong to the *Sarasaeschna pryeri*-group. In the *pryeri*-group, *S. gaofengensis* shares the razor-like male cerci with *S. tsaopiensis* Yeh and Chen described from Taiwan, to which it is believed to be closely related." 15555. Yuen, E.Y.L.; Dudgeon, D. (2015): Dietary dependence of predatory arthropods on volant aquatic insects in tropical stream riparia. Biotropica 48(2): 218-228. (in English) ["The dietary dependence on volant aquatic insects of eight species of predatory arthropods from three different orders was determined by stable isotope analyses in combination with three-source, two-isotope (C and N) Bayesian mixing models. The predators were collected from riparian zones along three streams in tropical Hong Kong during both the wet and dry seasons. Dietary importance of aquatic insects varied according to predator hunting modes, and showed a consistent pattern across all sites during the wet season. The web-building tetragnathid spider (*Orsinome diporusa*) had the greatest reliance (~40–55%) on this water-to-land subsidy, followed by two species of damselflies (40–50%) (*Rhinocypha perforata*, *Euphaea decorata*), three cursorial spiders (*Lycosidae*, *Pisauridae*, and *Sparassidae*: 32–51%) and two neustic Gerrids (17–36%). Such reliance also varied according to the microhabitat preferences of different cursorial spiders. Four species of predators (Gerrids and cursorial spiders) that were active year-round showed generally consistent reliance on aquatic insects between seasons, which probably reflected the observed lack of seasonal variability in the relative proportions of aquatic and terrestrial prey. There was a marked overlap in isotopic signatures of aquatic and terrestrial prey at all sites which, com-

bined with the absence of data on the extent to which isotopic fractionations may vary among individual species of prey and predators, contributes some uncertainty to the estimates of dietary compositions derived by mixing models. The findings of the present study are thus likely to be indicative rather than definitive. 15556. Yuto, C.M.M.; Nuneza, O.M.; Villanueva, J.T. (2015): Species diversity of the odonatofauna of Mts. Pinukis and Gimamaw, Zamboanga del Sur, Philippines. *Journal of Biodiversity and Environmental Sciences* 7(4): 135-146. (in English) ["Odonata is highly sensitive to various changes in the environment which makes it an excellent bioindicator of environmental health. This study was conducted to assess the species richness of Odonata in Mts. Pinukis and Gimamaw, Zamboanga del Sur, Philippines. Eleven sampling sites were surveyed comprising six sites in Mt. Pinukis and five sites in Mt. Gimamaw. Opportunistic sampling using sweep nets was conducted for a total of 192 man-hours. Biodiversity indices, cluster analysis, and detrended correspondence analysis were determined using Paleontological Statistics Software Package (PAST) version 2.17b. Thirty-five species were recorded belonging to 25 genera and 10 families with relatively low endemism of 40%. There was a more or less even species distribution. High relative abundance of 18.83% was observed in site 1. Site11 was observed to have the most number of endemic species. High species diversity was recorded in both Mts. Pinukis and Gimamaw. Detrended correspondence analysis showed that vegetation structure greatly influences habitat preferences of Odonata. It appears that human-induced disturbances limit the occurrence and abundance of the Odonata, especially the endemic species." (Authors)] Address: Nuñez, Olga, Department of Biological Sciences, Mindanao State University-Iligan Institute of Technology, Iligan City, Philippines. E-mail: olgamnuneza@yahoo.com

15557. Zebsa, R.; Khelifa, R.; Kahalerras, A. (2015): Emergence pattern, microhabitat choice, and population structure of the Maghribian endemic *Gomphus lucasii* Selys, 1849 (Odonata: Gomphidae) in northeastern Algeria. *Aquatic Insects* 36(3-4) (2014): 245-255. (in English) ["Emergence of *Gomphus lucasii* Selys, 1849, an unstudied Maghreb endemic, was synchronised by overwintering in the final stadium in the Seybouse River in northeastern Algeria. Regular collections revealed that half of the annual population emerged during 10 days, showing a typical 'spring species' emergence pattern. Sex ratio was slightly male biased (51%). Males and females did not differ in vertical stratification. Emergence support choice was not random, but rather depended on support height, body size, and daily population density. Mortality was caused mainly by ants, although deformity of teneral and bird predation were also important factors. *Gomphus lucasii* has been assessed as vulnerable (International Union for Conservation of Nature (IUCN) Red List), and the information provided in our

study will be helpful in future conservation efforts." (Authors)] Address: Zebsa, R., Département d'écologie et du génie de l'environnement, Faculté des Sciences de la Nature et de la Vie et des Sciences de la Terre et de l'Univers, Université 08 Mai 1945, Guelma 24000, Algérie

15558. Zebsa, R.; Khelifa, R.; Kahalerras, A. (2015): Adult movement pattern and habitat preferences of the Maghribian endemic *Gomphus lucasii* (Odonata: Gomphidae). *J. Insect Sci.* (2015) 15(1): 151; DOI: 10.1093/jisesa/iev128: 8 pp. (in English) ["The Algerian Cudtail (*Gomphus lucasii* Selys) (Odonata: Gomphidae) is a river-dwelling dragonfly and one of the least known gomphid in the Palearctic. A survey of the movement patterns and habitat requirements of adults was conducted in the largest currently known population, located in the Seybouse River (Northeast Algeria). Daily mark-release-resighting surveys along a 2.5 km stretch of the watercourse and within plots in terrestrial habitats were carried out; a total of 1,316 individuals were marked. The resighting rate along the watercourse was 8.13% and did not significantly vary with sex and age. Adult spatial distribution differed according to sex and age. Mature females were significantly further from the water than males. Mature males were observed not only along the watercourse but also far from the water, up to 450m where reproductive pairs in copula were recorded. Preferred maturation and foraging sites were open grasslands and dense wheat fields. Philopatry to reproductive sites had a mean of 1.11%, while philopatry to emergence site was lower (0.4%) and noted only in males. The mean distance of natal dispersal (from emergence to reproductive areas) was 596.564.94 m. The mean dispersal distance from one reproductive site to another was 180.976238.54 m. Both mature males and females preferred fast flowing water, but females were observed to oviposit in relatively small watercourses." 15564. Akram, W.; Ali-Khan, H.A. (2016): Odonate nymphs: Generalist predators and their potential in the management of dengue mosquito, *Aedes aegypti* (Diptera: Culicidae). *Journal of Arthropod-Borne Diseases* 10(2): 253-258. (in English) ["Background: Dengue is amongst the most serious mosquito-borne infectious disease with hot spots in tropical and subtropical parts of the world. Unfortunately, no licensed vaccine for the disease is currently available in medicine markets. The only option available is the management of dengue vector mosquito, *Aedes aegypti* (Diptera: Culicidae). Method: Predatory potential of five odonate nymphs namely *Anax parthenope*, *Bradinopyga geminate*, *Ischnura forcipata*, *Rhinocypha quadrimaculata*, and *Orthetrum sabina* were evaluated against the 4th instar larvae of the dengue vector mosquito, *Aedes aegypti*, under laboratory conditions. The consumption of the mosquito larvae was evaluated at three water volume levels viz., 1 liter, 2 liter and 3 liter. Results: The number of *Ae. aegypti* larvae consumed varied significantly among the five species, and at different levels of water volume ($P < 0.01$). However, the interaction between odonate nymphs and the water volumes was statistically non-significant ($P > 0.05$). *Ischnura forcipata* consumed the highest number of *Ae. aegypti* larvae ($n=56$) followed by *A. parthenope* ($n=47$) and *B. geminate* ($n=46$). The number of larvae consumed was decreased with increasing search area or water volume, and the highest predation was observed at 1-liter water volume. Conclusion: The odonate nymphs could be a good source of biological agents for the management of the mosquitoes at larval stages." 15565. Allen, A.M.; Singh, N.J. (2016): Linking movement ecology with wildlife management and conservation. *Front. Ecol. Evol.* 3:155.doi: 10.3389/fevo.2015.00155: 13 pp. (in English) ["A common challenge in species conservation and management is how to incorporate species movements into management objectives. There often is a lack of knowledge of where, when, and why species move. The field of movement ecology has grown rapidly in the last decade and is now providing the knowledge needed to incorporate movements of species into management planning. This knowledge can also be used to develop management strategies that are flexible in time and space and may improve the effectiveness of management actions. Therefore, wildlife management and conservation may benefit by strengthening the link with movement ecology. We present a framework that illustrates how animal movement can be used to enhance conservation planning and identify management actions that are complementary to existing strategies. The framework contains five steps that identify (1) the

movement attributes of a species, (2) their impacts on ecosystems, (3) how this knowledge can be used to guide the scale and type of management, (4) the implementation, and (5) the evaluation of management actions. We discuss these five steps in detail, highlighting why the step is important and how the information can be obtained. We illustrate the framework through a case study of managing a highly mobile species, the Atlantic salmon (*Salmo salar*), a harvested species of conservation concern. We believe that the movement-management framework provides an important, and timely, link between movement ecology and wildlife management and conservation, and highlights the potential for complementary, dynamic solutions for managing wildlife." 15567. Arbeiter, S.; Schulze, M.; Tamm, P.; Hahn, S. (2016): Strong cascading effect of weather conditions on prey availability and annual breeding performance in European bee-eaters *Merops apiaster*. Journal of Ornithology 157(1): 155-163. (in English, with German summary) ["Aerial insectivorous birds depend highly on favourable weather conditions for successful foraging because flight activity of insects is constrained by daily weather. Thus, the variation in weather conditions during reproduction, mediated by prey limitations, should be mirrored in annual reproduction performance, and finally in annual breeding success. We analysed the effect of local weather conditions on the availability of airborne insects and on the variation in brood size and nestling condition of European bee-eaters *Merops apiaster* at the northern edge of their range where years with adverse weather frequently occur. The availability of large flying insects, the common prey of bee-eaters, increased with

air temperatures and duration of daily sunshine. As predicted, local weather conditions affected reproductive performance with annual breeding success (mean 3.7 nestlings per breeding pair, range 1.7–4.9 nestlings) being up to 32 % higher in extraordinary dry and hot summers. Additionally, a nestling's body condition (residual mass) was also affected by sunshine duration during their growth period and internally was co-affected by the number of siblings and the individual rank within the sibling hierarchy. Thus, a prolonged duration of daily sunshine causes a cascade from higher insect flight activity, and, thus, higher food availability for chick-rearing bee-eaters, which finally translates into better chick body conditions and higher annual breeding success. Consequently reproduction and population development of European bee-eaters might be especially susceptible to regional changes in weather and climatic conditions."(Authors) The paper includes references to Odonata.] Address: Arbeiter, Susanne, Zool. 15568. Aschonitis, V.G.; Feld, C.K.; Castaldelli, G.; Turin, P.; Visonà, E.; Fano, E.A. (2016): Environmental stressor gradients hierarchically regulate macrozoobenthic community turnover in lotic systems of Northern Italy. Hydrobiologia 765: 131-147. (in English) ["Environmental stressors present a hierarchical influence on freshwater organisms. This study investigates the hierarchy of environmental stressor gradients, which regulate the composition of instream macroinvertebrate communities of northern Italy (Po Valley and the south-eastern Alps). Species and environmental data were derived from 585 monitoring sites. Environmental parameters were split into three groups, describing (i) ecoregional, (ii) hydromorphological, and (iii) water quality attributes. Partial Redundancy Analysis (partial RDA) was used to hierarchically rank the group effects, which were expressed as unique (group specific) and joint effects (of two groups together). Overall, ecoregion explained more variance (30.2%) than hydromorphology (24.8%) and water quality (22.3%). Unique effects were generally low, but ecoregional unique effects were twice as high as those of the other groups. The analysis of single environmental variables highlighted significant effects of anthropogenic impact related to the substrate size composition, riparian vegetation, flow conditions, and *Escherichia coli* (surrogate descriptor of organic fecal pollution). Such stressor hierarchies can support biodiversity conservation plans, while the high joint effects of stressor groups suggested the need for combined management activities, addressing the respective stressors and stressor groups in concert. Management measures addressing only one stressor group isolated from others are likely to be less effective, or even ineffective." (Authors) Taxa including Odonata are treated at genus level.] Address: Aschonitis, V.G., Department of Life Sciences and Biotechnology, University of Ferrara, Ferrara, Italy. E-mail: schvls@unife.it

15569. Berquier, C.; Antoine Orsini, A.; Ferrat, L.; Andrei-Ruiz, M.-C. (2016): Odonata Community Index – Corsica"

(OCIC): A new biological index based on adult odonate populations for assessment of the ecological status of watercourses in Corsica. *Ecological Indicators* 66: 163-172. (in English) ["Corsica is a French island in the western Mediterranean with numerous distinct geomorphological, landscape, and biological characteristics. These specific attributes, mostly related to insularity, are hardly taken into account by the biological indices currently recommended in the framework of the European Union Water Framework Directive "WFD" for assessing the ecological status of watercourses. Thus, this work has focused on developing an innovative biological index adapted to the specific context of territories such as Corsica, based on the Odonata group. In this context, imago sampling of Odonata was performed at 40 representative stations to assess the 33 major permanent rivers of the island. In parallel, various biological, hydrological, and physicochemical parameters affecting the ecological status of these organisms were recorded. The data collected on nearly 30 species of Odonata allowed for the accurate description of the typical populations of Corsican watercourses, highlighting this group's potential as a biological indicator. An indicator value was assigned to the 12 species identified as the most representative of these environments. The results were used to develop 5 biological indices based on simple statistical descriptors. The index that was found to be the best for assessing the ecological status of the watercourses, as indicated by correlation tests, was named "Odonata Community Index – Corsica" (OCIC), and was finally confronted with the 5 biological indices recommended by the WFD and currently used in Corsica. The results of this study confirm the significant potential of the OCIC index compared to other "official" indicators, that are limited in they do not accurately assess all territories. The results of our tests indicate that this new index using Odonata group appears to be a credible method that could potentially improve the evaluation system currently used for monitoring the ecological quality of watercourses in Corsica." 15570. Blecher, M. (2016): Hebrew names for insects toward environmental education and nature conservation: dragonflies and damselflies as a case study. *Negev, Dead Sea and Arava Studies* 7(3): 58-65. (in Hebrew, with English summary) ["The issue of the report is interdisciplinary: linking biological knowledge and environmental education, connecting zoological taxonomy with the Hebrew language. The necessity of Hebrew names for Israeli dragonflies and damselflies is explained and discussed, and the practice of creating those names is analyzed. The vernacular names were proposed for the taxonomical insect order (Odonata) comprehensively. A methodical consistent approach, as the base for suggesting the names, is briefly described. The complete and clarified names proposal (the first for an arthropods group of the country) was submitted to the Academy of the Hebrew Language. After lengthy process of detailed discussions in the Zoological Terminology Committee,

the Hebrew common names of dragonflies and damselflies have been approved by the Plenary Session of the Academy. The accepted names should be an important tool in education for biodiversity conservation and in promotion for fresh-water habitats protection. Additionally, an up-dated Odonata faunistic list of Israel is given. The list is a concise literature summary for practical conservation purposes." (Authors)] Address: Blecher, M., Israel Nature and Parks Authority - En Gedi Nature Reserve. E-mail: m.blecher@npa.org.il

15571. Boonsoong, B. (2016): Phoretic associations between *Nanocladius asiaticus* (Diptera, Chironomidae) and its hosts *Gestroiella* (Heteroptera, Naucoridae) and *Euphaea masoni* (Odonata, Euphaeidae) in streams in Western Thailand. *Annales de Limnologie - International Journal of Limnology* 52: 163-169. ["Phoretic associations between larvae of *Nanocladius* (Plecopteracoluthus) *asiaticus* (Diptera, Chironomidae) and two species in the genus *Gestroiella* (Heteroptera, Naucoridae) were studied in Kanchanaburi and Ratchaburi Provinces (Western Thailand). *Gestroiella siamensis* was used by chironomid larvae as a host more frequently than was *Gestroiella limnocoroides*. Moreover, *N. asiaticus* larvae were associated symphoretically with nymphs of *Euphaea masoni*. This is the first report of a symphoretic association involving *E. masoni*. Approximately 44% of the population of naucorids harboured symphoretic chironomids, whereas only 13% of damselfly nymphs were hosts of the chironomid larvae. Most of the brachypterous male (59%) naucorids hosted chironomid larvae. The attachment site of the chironomids was frequently along the mesofemur and mesosternum of the naucorid hosts. The chironomids were attached to the ventral sides of abdominal segments of *E. masoni* nymphs. There was a positive correlation in body length between chironomids and naucorids ($r=0.389$, $P<0.01$). There are many benefits of symphoresis in the Chironomidae, such as improved feeding opportunities, increased mobility, suitable pupation sites and decreased predation risks." 15572. Braun, A.P.; Phelps, Q.E. (2016): Channel Catfish habitat use and diet in the Middle Mississippi River. *The American Midland Naturalist* 175(1): 47-54. (in English) [Overall, vegetation, fish, and Cambaridae (freshwater crayfishes) made up the highest mean proportion of stomach contents by weight (27.5%, 20.6%, and 19.9% respectively). Trichoptera constituted the next highest proportion (4.6%), while Collembola, Coleoptera, Odonata, and Bivalvia were minor proportions "River modifications have had detrimental effects on biota that depend on river systems; therefore, information is needed to understand these effects and direct management efforts. Channel catfish (*Ictalurus punctatus*) are important recreationally, commercially, and ecologically in the Middle Mississippi River (MMR), but few studies have examined their habitat requirements, and food

habits have not been evaluated in the MMR. Information about habitat use and food habits could help direct management efforts for channel catfish. To more thoroughly understand the synergistic relation between channel catfish and the associated habitat, we used data from the United States Army Corps of Engineer's Long-Term Resource Monitoring Program to evaluate channel catfish use of large-scale river features (i.e., macrohabitats) and more fine scale mesohabitats (i.e., substrate type, depth, and velocity). Stomach contents from channel catfish were identified and quantified to determine the relative importance of specific prey items in diets. Channel catfish presence was positively affected by current but negatively affected by depth. Off-channel habitats appeared more suitable for channel catfish. In terms of food habits, Cambaridae, fish, and vegetation were most frequently found in the diet, but a variety of other food items were consumed. Conserving premodification habitat characteristics, such as open side channels, shallow sandbars, and seasonally inundated floodplains, as well as habitats with high forage productivity, should help to sustain a stable population of channel catfish in the MMR. Future studies could examine the tenets of the optimal foraging theory within these habitats to determine the mechanisms regulating channel catfish habitat use and prey selection." 15573. Brown, A.L.; Robinson, B.W. (2016): Variation in behavioural plasticity regulates consistent individual differences in *Enallagma* damselfly larvae. *Animal Behaviour* 112: 63-73. (in English) ["Highlights: •Larvae of different *Enallagma* species experience constant or variable predation risk. •Larvae predictably vary in plastic behaviour in response to fish predator cues. •More plasticity is associated with reduced variation in plasticity among individuals. •Less variation in plasticity enhances consistent individual differences in behaviour. •Variation in behavioural plasticity and in mean behaviour regulates behaviour types. Plastic behavioural responses by individuals to different conditions and consistent individual differences in mean behaviour across situations both contribute to variation in a population. The relationship between behavioural plasticity and consistent individual differences is not clearly understood but may help predict personality variation in animals. High variation in mean behaviour and low variation in individual plastic responses will tend to maintain the rank order of individuals across situations and so permit consistent individual differences. Conversely, low variation in mean behaviour and high variation in plastic responses, by changing the rank orders of individuals, will erode consistent individual differences. Thus, selection that reduces variation in individual plastic responses should increase the opportunity for consistent individual differences in a population. We tested for relationships between heterogeneous predation regimes, the mean and variance of behavioural plasticity and consistent individual differences among three species groups of larval damselflies. Larvae of *Enallagma signatum*

probably face consistent predation from fish over successive generations, whereas *Enallagma ebrium/hageni* and *Enallagma annexum/boreale* face a changing predation regime over generations either from fish or larval dragonflies. The behavioural reaction norms of larvae in repeated exposure trials to cues from a predatory fish, dragonfly larvae or no predator differed between species groups. *Enallagma ebrium/hageni* expressed the most consistent plastic response to predator cues, less variability in plasticity and greater consistent individual differences across cues compared to more variable plastic responses and low consistent individual differences in *E. signatum*. Selection on behavioural plasticity may enhance consistent individual differences in *E. ebrium/hageni* whereas relaxing selection on plasticity may reduce consistent individual differences in *E. signatum*. More generally, selection on plastic behaviour may enhance behavioural types while selection on mean behaviour may reduce behavioural types in animal populations." (Authors)] Address: Robinson, Beren, Department of Integrative Biology, University of Guelph, Guelph, ON, N1G 2W1, Canada. E-mail: berenrob@uoguelph.ca

15574. Bruni, G.; Ricciardi, G.; Vannini, A. (2016): Effectiveness of artificial amphibian breeding sites against non-native species in a public protected area in Tuscany, Italy. *Conservation Evidence* (2016) 13, 12-16: 12-13. (in English) ["The spread of non-native invasive species is among the factors thought to be responsible for the recent global declines in amphibian populations. In a Protected Natural Area of Local Interest in Tuscany, Italy, we tested approaches for preserving the local amphibian populations threatened by the presence of the red swamp crayfish *Procambarus clarkii*. The construction of artificial breeding ponds, with suitable vertical barriers, was initially effective in preventing the spread of the red swamp crayfish and created a source site for amphibians, in particular newt species. Unfortunately, five years after construction, the breeding sites were colonized by fish and crayfish, possibly due to the actions of members of the public.... In addition to the target species, many aquatic insects, such as dragonflies and damselflies (Odonata) (e.g. *Anax imperator*, *Crocothemis erythraea*, *Libellula quadrimaculata*) successfully colonized the reconstructed habitats." 15575. Callahan, M.S.; McPeck, M.A. (2016): Multi-locus phylogeny and divergence time estimates of *Enallagma* damselflies (Odonata: Coenagrionidae). *Molecular Phylogenetics and Evolution* 94, Part A: 182-195. (in English) ["Highlights: •*Enallagma* damselflies show complex diversification across North America and Eurasia. •Four subclades radiated in the Pleistocene to produce 28 extant species. •Both speciation and extinction rates increased over the last 1.5 million years. Reconstructing evolutionary patterns of species and populations provides a framework for asking questions about the impacts of climate change. Here we

use a multilocus dataset to estimate gene trees under maximum likelihood and Bayesian models to obtain a robust estimate of relationships for a genus of North American damselflies, *Enallagma*. Using a relaxed molecular clock, we estimate the divergence times for this group. Furthermore, to account for the fact that gene tree analyses can overestimate ages of population divergences, we use a multi-population coalescent model to gain a more accurate estimate of divergence times. We also infer diversification rates using a method that allows for variation in diversification rate through time and among lineages. Our results reveal a complex evolutionary history of *Enallagma*, in which divergence events both predate and occur during Pleistocene climate fluctuations. There is also evidence of diversification rate heterogeneity across the tree. These divergence time estimates provide a foundation for addressing the relative significance of historical climatic events in the diversification of this genus." 15576. Campos, F.; Velasco, T.; Sanz, G.; Casanueva, P.; Albuquerque, M.T.D.; Antunes, M.H.R. (2016): *Ischnura graellsii* (Insecta: Odonata): a water pollution biovulnerable indicator-probability mapping using spatial uncertainty. *River Research and Applications* 32: 483-489. (in English) ["Monitoring changes of anthropogenic impacts from a broad scope of species in biodiversity research require practical, easy-to-use and efficient assessment as well as monitoring methods. Odonates are a valuable tool for assessing freshwater systems' quality and have been used as bioindicators of environmental variety. The Águeda watershed, located in the central west of the Iberian Peninsula, shows an exponential increase in the last 60 years of natural resource exploitation coupled with alterations in consumer habits, causing significant environmental changes and deferred direct effects on the natural habitats. Fourteen river sites, selected a priori, were sampled. Adult odonates were collected using standardized methods. Selected environmental variables and water quality parameters were evaluated in situ. Precipitation and altitude were the most important physical, environmental variables in explaining the assemblage structure. Meaningful abiotic-biotic as well as biotic-biotic relationships were set up. Furthermore, situations in the urbanized watershed area showed to be highly impacted and closely related with damselfly *Ischnura graellsii*, which should be targeted as a possible vulnerability indicator for polluted fresh waters. A probability map for *Ischnura graellsii* distribution was performed using indicator kriging with external drift and spatial uncertainty obtain through the calculation of two categorical maps (binary), corresponding to the mean (0.485) and the trimmed mean by discharging the 10% lower distribution tail (0.533). The subsequent overlapping of both categorical maps (binary) allowed the definition of the higher spatial uncertainty map for surface water contamination." Cabral, no 12, 6000-084 Castelo Branco, Portugal. E-mail: teresal@ipcb.pt

15577. Casillas-Barragán, I.; Costa-Pereira, P.; Cardoso Peixoto, P.E. (2016): Perceived predation risk decreases movement and increases aggregation of Amazon milk frog (*Anura*, *Hylidae*) tadpoles throughout ontogeny. *Hydrobiologia* 765: 379-386. (in English) ["In order to maximize escaping success, prey may change their predator avoidance behaviours according to their susceptibility. Morphological development during ontogeny may lead to different susceptibility to predators. Consequently, prey may exhibit different predator avoidance strategies according to the ontogenetic state. In this study, we used tadpoles of the Amazon milk frog *Trachycephalus resinifictrix* to evaluate how variation in the ability to actively escape owed to the mobility acquired through ontogeny affects the adoption of predator avoidance strategies. We sampled tadpoles (N = 384) in temporary ponds and divided them in four consecutive developmental stages according to body size and mobility capacity. Subsequently, we measured their movement and spatial distribution when subjected to chemical cues of predators or control solutions. We found that they spent less time moving and increased spatial aggregation after receiving solutions with predator cues, independent of their developmental stage. These results indicate that the variation in escape capacity through larval ontogeny does not determine their antipredator strategy. Since tadpoles of *T. resinifictrix* typically grow in environments with reduced space for active escaping, such as tree holes and bromeliads, it may be that the ability to flee from predators is absent, even when this behaviour increases the survival chances." 15578. Chainthong, D.; Boonsoong, B. (2016): Description of two final stadium *Onychogomphus* larvae from Thailand (Odonata: Gomphidae). *Zootaxa* 4066(5): 561-570. (in English) ["The final stadium larvae of *Onychogomphus castor* Lieftinck and *O. duaricus* Fraser are described and illustrated for the first time based on reared specimens from Thailand. The taxonomic characteristics of the larvae of the genus *Onychogomphus* are discussed and summarized. The larva of *O. castor* differs from other Southeast Asian species in having distinct mid-dorsal spines on S2-9, divergent wing pads reaching S5, and lateral spines on S6-9. The larva of *O. duaricus* has a weakly swollen third antennal segment, with short blunt mid-dorsal spines on S2-9, divergent wing sheaths reaching the middle of S4, and lateral spines present on S7-9." 15580. Chandra, G.; Mondal, B.; Bandyopadhyay, S.; Ghosh, A. (2016): Sex-specific functional responses of dragonfly naiads *Rhodothemis rufa* on *Culex quinquefasciatus* larvae in laboratory bioassay. International Journal of Pest Management 62(2): 135-139. (in English) ["Laboratory bioassay was conducted to establish the biocontrol potentiality of naiads (aquatic nymphal stage) of *Rhodothemis rufa* (Rambur, 1842) against larvae of *Culex quinquefasciatus*, a common vector of filariasis in Tropical countries. From the study, it was noticed that in laboratory condition, the rate of predation of males of *R. rufa* was higher than that of females of almost same size and same species. The results of the present study revealed that both sexes displayed a density-dependent decelerating type-II functional response as the logistic regression estimated a significant negative linear parameter (P1 value of -0.330 and -0.151 for males and females, respectively). Attack rate was almost similar for both sexes (0.082); however, handling time is less in males (0.62 min) than in females (0.852 min). The predator species usually coexist in the same aquatic habitat to that of mosquito larvae and can be effectively used in field condition to reduce the larval densities of mosquitoes in temporary or permanent aquatic water bodies." 15581. Chen, Y.H.; Skote, M. (2016): Gliding performance of 3-D corrugated dragonfly wing with spanwise variation. Journal of Fluids and Structures 62: 1-13. (in English) ["Computational fluid dynamics (CFD) analyses are conducted to evaluate the gliding performance of a three-dimensional (3-D) corrugated wing while considering variations in the corrugation pattern across the wing span. Comparisons with the smoothly profiled counterpart assess the overall effect of wing corrugation on the gliding performance of the 3-D dragonfly wing, with primary focus on the effect of three-dimensionality as compared to the 2-D model. Earlier simulations of both 2-D and 3-D gliding corrugated wings showed oscillations on lift and drag, while in nature, such force fluctuation would be undesirable and unrealistic. In contrast, no non-realistic fluctuations are present in this simulation. The feature included here, which has been neglected in the earlier studies, namely the variation of leading edge orientation along the wing span, is the crucial detail for

preventing such non-realistic oscillations. Furthermore, strong spanwise flow occurs in the 3-D corrugated wing used in this study, which earlier models have been incapable to capture." (in English) ["The diets of the Intermediate Egret *Egretta intermedia*, Little Egret *E. garzetta*, and Cattle Egret *Bubulcus ibis* were examined by analyzing nestling regurgitations collected during the breeding season in 2005 at a colony in Asan, South Korea. Intermediate Egret nestlings mainly fed on insects (86.7% of total prey items), but fish were the most important group by biomass (64.3% of total biomass). Little Egret nestlings fed mainly on insects and fishes (43.4% and 33.2% of total items, respectively), and fish contributed 64.2% to the total biomass consumed. Cattle Egret chicks were mainly fed invertebrate prey (96.5% of total items), such as insects and spiders, which comprised just 64.3% of the total biomass of their diet. Loaches and aquatic insect larvae (mainly Odonata and Coleoptera) comprised a large proportion of the nestling diet of the three egret species. This suggests that all species forage primarily in rice fields, which represented the most extensive habitat surrounding the breeding colony." 15583. Cooper, I.A.; Brown, J.M.; Getty, T. (2016): A role for ecology in the evolution of colour variation and sexual dimorphism in Hawaiian damselflies. Journal of Evolutionary Biology 29(2): 418-427. (in English) ["Variation in traits that are sexually dimorphic is usually attributed to sexual selection, in part because the influence of ecological differences between sexes can be difficult to identify. Sex-limited dimorphisms, however, provide an opportunity to test ecological selection disentangled from reproductive differences between the sexes. Here, we test the hypothesis that ecological differences play a role in the evolution of body colour variation within and between sexes in a radiation of endemic Hawaiian damselflies. We analyzed 17 *Megalagrion* damselflies species in a phylogenetic linear regression, including three newly-discovered cases of species with female-limited dimorphism. We find that rapid colour evolution during the radiation has resulted in no phylogenetic signal for most colour and habitat traits. However, a single ecological variable, exposure to solar radiation (as measured by canopy cover) significantly predicts body colour variation within sexes (female-limited dimorphism), between sexes (sexual dimorphism), and among populations and species. Surprisingly, the degree of sexual dimorphism in body colour is also positively correlated with the degree of habitat differences between sexes. Specifically, redder colouration

is associated with more exposure to solar radiation, both within and between species. We discuss potential functions of the pigmentation, including antioxidant properties that would explain the association with light (specifically UV) exposure, and consider alternative mechanisms that may drive these patterns of sexual dimorphism and colour variation." 15585. Cordero-Rivera, A. (2016): Demographics and adult activity of *Hemiphlebia mirabilis*: a short-lived species with a huge population size (Odonata: Hemiphlebiidae). *Insect Conservation and Diversity* 9: 108-117. (in English) ["(1.) Rare species are expected to be more susceptible to extinction, particularly if rarity can be used to describe several characteristics for a particular species. *Hemiphlebia mirabilis*, an endemic damselfly known from a few sites in the South of Australia and Tasmania, has been considered at risk of imminent global extinction, given its small population size, its localised distribution, and the fact that it is a 'living fossil', described as the oldest extant damselfly. (2.) One population found in a protected wetland in Victoria, was studied by behavioural observations of marked animals,

during Nov-Dec 2013. Results indicate that *H. mirabilis* is a short-lived species, with a mature lifespan of about 1 week in males and 4 days in females. (3.) Population size estimates and field observations indicate that this population is huge, likely over one million individuals per generation. Adults show little mobility and fly for short distances, being inactive most of the time, particularly at temperatures below 17 °C or over 35 °C. (4.) The low mobility and cryptic coloration, and the inaccessibility of its preferred habitat might explain why huge populations like the one studied here have remained unnoticed until recently. Nevertheless, both sexes show frequent abdominal flicking displays, and fast rotations over the perching support, both behaviours apparently unique to this species, making them highly conspicuous to human observers. It is concluded that *H. mirabilis* should not be regarded as critically endangered." (Authors)] Address: Cordero Rivera, A., Depto de Ecología e Biología Animal, Universidade de Vigo, E.U.E.T. 15586. Cordero-Rivera, A. (2016): Sperm removal during copulation confirmed in the oldest extant damselfly, *Hemiphlebia mirabilis*. *PeerJ Preprints* 4:e1810v1 <https://doi.org/10.7287/peerj.preprints.1810v1>: (in English) ["Post-copulatory sexual selection may favour mechanisms to reduce sperm competition, like physical sperm removal by males. To investigate the origin of sperm removal, I studied the reproductive behaviour and mechanisms of sperm competition in the only living member of the oldest damselfly family, *Hemiphlebia mirabilis*, one species that was considered extinct in the 1980s. This species displays scramble competition behaviour, whose males search for females with short flights and both sexes exhibit a conspicuous "abdominal flicking". This behaviour is used by males during an elaborate precopulatory courtship, unique among the Odonata. Females use a similar display to reject male attempts to form tandem, but eventually signal receptivity by a particular body position. Males immobilise females during courtship using their legs, which, contrarily to other damselflies, never autotomize. Copulation is short (range 4.1-18.7 min), and has two stages. In the first stage, males remove part of the stored sperm, and inseminate during the second stage, at the end of mating. The examination of genitalia indicates that males have two horns covered by back-oriented spines, which match the size and form of female genitalia. The volume of sperm in females after copulation was 2.8 times larger than the volume stored in females whose copulation was interrupted at the end of stage I, indicative of a significant sperm removal. These results point out that sperm removal is an old character in the evolution of odonates, probably dating back to the Permian." N. (2016): The status of *Rhionaeschna galapagoensis* (Currie, 1901) with notes on its biology and a description of its ultimate instar larva (Odonata, Aeshnidae). *Animal Biodiversity and Conservation* 39(1): 45-63. (in English, with Spanish summary) ["A morphological, molecular, and behavioural characterization of *R. galapagoensis* is presented, based on a series of specimens and observations from San Cristóbal Island, Galápagos, including both adults and larvae. Several of the characters proposed earlier to distinguish between the adults of this species and its closest relative, *R. elsia*, are found to be variable, but the presence of a black band over the fronto-clypeal suture is confirmed as a good diagnostic character. The ultimate instar larvae of *R. galapagoensis* is described for the first time, and diagnosed from its closest relatives by a combination of characters, including the acute angle between the prothoracic apophyses, absence of lateral spines on abdominal segment 6, and length of cerci relative to paraprocts. Molecular analysis confirmed that *R. galapagoensis* and *R. elsia* are sister species, and showed that their genetic distance is the closest among the analyzed species, which is to be expected given the young age of the Galápagos Islands. The larvae of *R. galapagoensis* were very common and widespread in the mountain streams and a pond in the southwest of San Cristóbal. Swarms of tens of individuals formed at sunrise in the coastal vegetation, together with adults of *Tramea cf. cophysa*, feeding on small flying insects. Males showed patrolling behaviour on small sections of the streams and at a pond. Only one copulation was observed, lasting 10 minutes. Females oviposited alone on floating vegetation in running and standing waters. Our observations corroborate that *R. galapagoensis* and *R. elsia* are two parapatric species, morphologically and genetically close. In San Cristóbal, *R. galapagoensis* had large populations, apparently not threatened." (2016): Landscape complexity and farmland biodiversity: Evaluating the CAP target on natural elements. *Journal for Nature Conservation* 30(1): 19-26. (in English) ["Increasing pressures on natural areas and limited conservation budgets require, particularly in rural landscapes in the Western world, an immediate answer to the question how much natural area is required to provide a sustainable future for wild plant and animal species on farmland. The European Union proposed in its Common Agricultural Policy that 3–7% of EU farmland should be managed as ecological focus area (EFA) in order to halt biodiversity loss. For the first time, we empirically assessed the implications of this policy by evaluating the effects of the density of natural elements in agricultural landscapes on multi-taxon species richness, including vascular plants, breeding birds, butterflies, hoverflies, dragonflies, and grasshoppers for an entire European country. We found that species richness increased either as

linear or as a logarithmic function of the proportion of natural elements in the landscape, but not with a sigmoid function as predicted by the 'intermediate landscape complexity' hypothesis. Even landscapes with 3–7% of natural elements harboured generally 37–75% of maximum species richness, indicating good potential of implementing the CAP target to preserve farmland biodiversity. However, differences between the 3 and 7% limits were considerable for butterflies, birds, and hoverflies. Also, the shape of the species richness response was shown to differ between landscape types for butterflies. Thus, it may be necessary to develop tailor-made guidelines at regional levels." (2016): Diverse circular replication-associated protein encoding viruses circulating in invertebrates within a lake ecosystem. *Infection, Genetics and Evolution* 39: 304-316. (in English) ["Highlights: •Sampled molluscs, insect larvae, water and benthic sediments for CRESS DNA viruses. •Recover 169 circular molecules (160 CRESS DNA molecules, nine circular molecules). •Identification of a new RNA–DNA hybrid virus. •Strong association between viral sequences between water and browser organisms. •Strong association between viral sequences between sediments and undefended prey species. Abstract: Over the last five years next-generation sequencing has become a cost effective and efficient method for identifying known and unknown microorganisms. Access to this technique has dramatically changed the field of virology, enabling a wide range of environmental viral metagenome studies to be undertaken of organisms and environmental samples from polar to tropical regions. These studies have led to the discovery of hundreds of highly divergent single stranded DNA (ssDNA) virus-like sequences encoding replication-associated proteins. Yet, few studies have explored how viruses might be shared in an ecosystem through feeding relationships. Here we identify 169 circular molecules (160 CRESS DNA molecules, nine circular molecules) recovered from a New Zealand freshwater lake, that we have tentatively classified into 51 putatively novel species and five previously described species (*DflaCV-3*, -5, -6, -8, -10). The CRESS DNA viruses identified in this study were recovered from molluscs (*Echydrella menzeisii*, *Musculium novaezelandiae*, *Potamopyrgus antipodarum* and *Physella acuta*) and

insect larvae (*Procordulia grayi*, *Xanthocnemis zealandica*, and *Chironomus zealandicus*) collected from Lake Sarah, as well as from the lake water and benthic sediments. Extensive diversity was observed across most CRESS DNA molecules recovered. The putative capsid protein of one viral species was found to be most similar to those of members of the Tombusviridae family, thus expanding the number of known RNA–DNA hybrid viruses in nature. We noted a strong association between the CRESS DNA viruses and circular molecules identified in the water and browser organisms (*C. zealandicus*, *P. antipodarum* and *P. acuta*), and between water sediments and undefended prey species (*C. zealandicus*). However, we were unable to find any significant correlation of viral assemblages to the potential feeding relationships of the host aquatic invertebrates." 15593. Dickens, C.W.S.; Graham, P.M. (2016): The South African Scoring System (SASS) Version 5 Rapid Bioassessment Method for Rivers. *African Journal of Aquatic Science* 27: 1-10. (in English) ["The assessment of biota in rivers is a widely recognized means of determining the condition or 'health' of rivers. Benthic macroinvertebrates, in particular, are recognized as valuable organisms for bioassessments, due largely to their visibility to the naked eye, ease of identification, rapid life cycle often based on the seasons and their largely sedentary habits. Numerous bioassessment techniques have been developed over the last three decades, varying in complexity and region of implementation. South Africa has an exemplary history in this field, culminating in the refinement of invertebrate and other techniques and their application in a National River Health Programme. The method presented here is a refinement of the highly successful SASS (South African Scoring System) method developed by Chutter (1994), which forms the backbone of this programme. This paper takes the method to a level where it can, and has been, accredited to ISO standards. The principal changes made include the tighter definition of the technique and the sampling and analytical methods, as well as the introduction of quality control procedures. Some changes have also been made to the list of invertebrates used in this method. Field trials were conducted to test the variability of the method. Of the various indices available to the method, the ASPT is the most consistent over all biotopes (lowest CV%). On the other hand, of the biotopes examined the Gravel/Sand/Mud (GSM) combination is the most variable with respect to the SASS Score and number of taxa encountered. The spatial variability on a reach of river with similar water quality characteristics was found to be statistically negligible. However, one generally finds that statistically significant differences occur between the SASS Scores and the number of taxa counted by different operators. The ASPT, on the other hand, is a more consistent and repeatable measure of river health assessment and, within a given reach of river and considering all biotopes, the differences in results produced by different operators were statistically negligible. The results highlight the need for appropriate competency-based training and consistent application of the method." (Authors) Taxa including Odonata are treated at family level.] Address: Dickens, C.W.S., Hydrobiology, Umgeni Water, P O Box 9, Pietermaritzburg, 3200, South Africa. 15594. Dorrington, G.E. (2016): Heavily loaded flight and limits to the maximum size of dragonflies (Anisoptera) and griffenflies (Meganisoptera). *Lethaia* 49(2): 261-274. (in English) ["An original hypothesis is presented that the maximum mass and size of living anisopteran dragonflies are constrained by a physiological performance limit: the wing muscle power required to permit reproductively successful males to carry heavier females in the so-called 'wheel position' in flight. It is proposed that the same limit cannot have applied to all fossil Odonatoptera. As the physiology of the giant Carboniferous griffenfly *Namurotypus sippeli* precludes flight in the wheel position, it did not need to carry any substantial load aside from exogenous aerial prey. Based

on its thorax dimensions, it is argued that *Namurotypus* flew with a relatively low maximum specific muscle power output in comparison with living Anisoptera. The extinction of some families of large Mesozoic Odonoptera may have been exacerbated by competition with smaller (stem-) Anisoptera that evolved higher specific power outputs and superior flight performance similar to living Anisoptera. To investigate the credibility of this flight-performance size-limit hypothesis and its consequences, an analysis of the scaling of the required flight power and available muscle power is presented using allometric relations. It is found that for living Anisoptera and fossil Odonoptera, there are different limiting sizes, above which the required specific flight power would exceed the available muscle specific power. These limits are directly related to maximum load-carrying capacity and the atmospheric air density at the habitual altitude. It is suggested that the largest living species of Petaluridae, *Petalura ingentissima*, is close to the proposed Anisoptera size limit at current near-sea-level air density conditions." 15599. Espanha, J.; de Vasconcelos, M.F.; Eterovick, P.C. (2016): The role of tadpole coloration against visually oriented predators. *Behavioral Ecology and Sociobiology* 70(2): 255-267. (in English) ["An animal's vulnerability to predators can be influenced by its behaviour, morphology, body size, coloration, habitat preferences, and palatability. We tested whether the coloration of *Bokermannohyla saxicola* and *Scinax machadoi* tadpoles affects their survival when exposed to local visually oriented predators at a site in southeastern Brazil. We tested three aquatic invertebrates (*Aeshnidae*, *Belostoma* sp., *Lethocerus* sp.) and birds as tadpole predators. We predicted that predation rates would differ depending on the substrate where the tadpoles positioned themselves (light or dark), hypothesizing that each tadpole would use preferentially a background that conferred camouflage and that predation levels would be lower on such backgrounds compared to others. *B. saxicola* had higher survivorship than *S. machadoi* on light backgrounds at some instances, in accordance with its crypsis hypothesis. However, *B. saxicola* tadpoles did not use light backgrounds more often than dark ones. *S. machadoi* coloration looked disruptive on both light and dark backgrounds, and tadpoles showed no preference or differences in survival rates between these backgrounds. Predation rates did not differ between the two species in a way that could confirm a previous hypothesis of aposematic/mimetic coloration for *S. machadoi* tadpoles. Our results show that colorations that appear to function to impair visual detection may play this role at some circumstances but not others. Tadpole colorations may have evolved in another context, in which avoiding visual detection by predators was a stronger selective pressure. In a context with lower predation pressure from visually oriented predators, the expected background choice behaviour for increased camouflage

may not be strongly selected for." (Authors)] Address: Eterovick, Paula, Programa de Pós Graduação em Biologia de Vertebrados, Pontifícia Universidade Católica de Minas Gerais, Belo Horizonte, 30535-610, Brazil. E-mail: pcterovick@gmail.com

15600. Fauziyah, S.; Soesilohadi, R.C.H.; Retnoaji, B.; Alam, P. (2016): Dragonfly wing venous cross-joints inspire the design of higher-performance bolted timber truss joints. *Composites Part B: Engineering* 87: 274-280. (in English) ["This communication concerns the design and development of high performance biomimetic timber joints as inspired by the venous cross-joints of dragonfly wings. A special cross-joint configuration in *Crocothemis servilia* is identified. Between the veins of this cross-joint is a resilin envelope. Finite element modelling reveals that the presence of this resilin envelope reduces the levels of localised stress in the jointing region. By gaining an understanding of the structure and function of this dragonfly wing joint, dragonfly-joint inspired timber trusses are developed by integrating low-modulus adhesives around bolted connectors. We find that not only are the properties of strength, stiffness, toughness and deformability of bolted truss joints vastly improved on applying dragonfly-mimicking technology, but that the fatigue resistance is also enhanced. This preliminary work is an important step forward in the design and development of high-performance biomimetic joints for timber construction." 15602. Finley, M.L.D.; Kidd, K.A.; Curry, R.A.; Lescord, G.L.; Clayden, M.G.; O'Driscoll, N.J. (2016): A comparison of mercury biomagnification through lacustrine food webs supporting Brook Trout (*Salvelinus fontinalis*) and other salmonid fishes. *Frontiers in Environmental Science* 4 (Article23): 13 pp. (in English) ["Methylmercury (MeHg) bioaccumulation in lower-trophic-level organisms and its subsequent biomagnification through food webs differs in magnitude among lakes and results in intraspecific variability of

MeHg in top predator fishes. Understanding these differences is critical given the reproductive and neurotoxic effects of MeHg on fishes and their predators, including humans. In this study we characterized the food webs of five lakes in New Brunswick, Canada, supporting Brook Trout (*Salvelinus fontinalis*) using measures of relative trophic position ($\delta^{15}\text{N}$) and carbon sources ($\delta^{13}\text{C}$), determined the concentrations of MeHg in invertebrates and total Hg (THg) in fishes, and quantified MeHg biomagnification from primary to tertiary consumers. Methyl Hg and THg concentrations were highest in biota from lakes with lower pH. The trophic magnification slopes (TMS; $\log \text{Hg}$ vs. $\delta^{15}\text{N}$) varied significantly among lakes (0.13–0.20; ANCOVA, $p = 0.031$). When combined with data from other salmonid lakes in temperate and Arctic Canada ($n = 36$), among-system variability in TMS was best, but weakly, positively predicted by aqueous total phosphorous ($p = 0.028, 0.109$). These results suggest that lake productivity directly or indirectly influences the biomagnification of MeHg through diverse food webs supporting salmonids." 15603. Freeland-Riggert, B.T.; Cairns, S.H.; Poulton, B.C.; Riggert, C.M. (2016): Differences found in the macroinvertebrate community composition in the presence or absence of the invasive alien crayfish, *Orconectes hylas*. *PLoS ONE* 11(3): e0150199. doi:10.1371/journal.pone.0150199: 27 pp. (in English) ["Introductions of alien species into aquatic ecosystems have been well documented, including invasions of crayfish species; however, little is known about the effects of these introductions on macroinvertebrate communities. The woodland crayfish (*Orconectes hylas* (Faxon)) has been introduced into the St. Francis River watershed in southeast Missouri and has displaced populations of native crayfish. The effects of *O. hylas* on macroinvertebrate community composition were investigated in a fourth-order Ozark stream at two locations, one with the presence of *O. hylas* and one without. Significant differences between sites and across four sampling periods and two habitats were found in five categories of benthic macroinvertebrate metrics: species richness, percent/composition, dominance/diversity, functional feeding groups, and biotic indices. In most seasons and habitat combinations, the invaded site had significantly higher relative abundance of riffle beetles (Coleoptera: Elmidae), and significantly lower Missouri biotic index values, total taxa richness, and both richness and relative abundance of midges (Diptera: Chironomidae). Overall study results indicate that some macroinvertebrate community differences due to the *O. hylas* invasion were not consistent between seasons and habitats, suggesting that further research on spatial and temporal habitat use and feeding ecology of Ozark crayfish species is needed to improve our understanding of the effects of these invasions on aquatic communities." 15604. Fujimoto, M.S.; Suvorov, A.; Jensen, N.O.; Clement, M.J.; Bybee, S.M. (2016): Detecting false positive sequence homology: a machine learning approach. *BMC Bioinformatics* (2016) 17:101. DOI 10.1186/s12859-016-0955-3: 11 pp. (in English) ["Background: Accurate detection of homologous relationships of biological sequences (DNA or amino acid) amongst organisms is an important and often difficult task that is essential to various evolutionary studies, ranging from building phylogenies to predicting functional gene annotations. There are many existing heuristic tools, most commonly based on bidirectional BLAST searches that are used to identify homologous genes and combine them into two fundamentally distinct classes: orthologs and paralogs. Due to only using heuristic filtering based on significance score cutoffs and having no cluster post-processing tools available, these methods can often produce multiple clusters constituting unrelated (non-homologous) sequences. Therefore sequencing data extracted from incomplete genome/transcriptome assemblies originated from low coverage sequencing or produced by de novo processes without a reference genome are susceptible to high false positive rates of homology detection. Results: In this paper we develop biologically informative features that can be extracted from multiple sequence alignments of putative homologous genes (orthologs and paralogs) and further utilized in context of guided experimentation to verify false positive outcomes. We demonstrate that our machine learning method trained on both known homology clusters obtained from OrthoDB and randomly generated sequence alignments (non-homologs), successfully determines apparent false positives inferred by heuristic algorithms especially among proteomes recovered from low-coverage RNA-seq data. Almost ~42 % and ~25 % of predicted putative homologies by InParanoid and HaMStR respectively were classified as false positives on experimental data set (For the experimental data set (OD_S) we used 18 Odonata (dragonflies and damselflies) and 2 Ephemeroptera (mayflies) species.). Conclusions: Our process increases the quality of output from other clustering algorithms by providing a novel post-processing method that is both fast and efficient at removing low quality clusters of putative homologous genes recovered by heuristic-based approaches." 15605. Golfieri, B.; Hardersen, S.; Maiolini, B.; Surian, N. (2016): Odonates as indicators of the ecological integrity of the river corridor: Development and application of the Odonate River Index (ORI) in northern Italy. *Ecological Indicators* 61(2): 234-247. (in English) ["The assessment of the ecological conditions of rivers is crucial for their appropriate management and restoration. Bioindicators commonly used to evaluate the river status (i.e. diatoms, aquatic macrophytes, benthic macroinvertebrates and fish) detect alterations of water quality, but are not particularly sensitive to hydromorphological degradation, which is another relevant pressure in river systems. Furthermore, those bioindicators are usually applied only to flowing channels. We developed

a new multimetric index, the Odonate River Index (ORI), to assess the conditions of the whole corridor in alluvial rivers. The ORI is a development of an evaluation system proposed in Austria, and based on the Odonate Habitat Index (OHI). Odonates were chosen as bioindicators for the ecological integrity of the river corridor, since this taxon provides information on the conditions of their aquatic breeding sites, as well as on the surrounding terrestrial areas, due to its amphibiotic life cycle. We used a case study of 18 reaches from six Italian Alpine rivers, characterized by different morphological conditions and level of human impact. Within each study reach, we selected four sites, both lotic and lentic sites. Dragonfly surveys consisted in field observation of adults, and collection of larvae and exuviae. To define the best sampling strategy, we compared the results of the ORI metrics obtained varying the input data by combining different sampling methods: the best compromise between effort and exhaustiveness was obtained coupling the observation of adults with the collection of exuviae. We found the ORI to be a robust and reliable tool to assess the status of the river corridor in a wide range of environmental conditions and river morphology, being particularly suitable to detect hydromorphological degradation and alterations of the structure of aquatic and riparian vegetation. We identified two limiting factors for the applicability of this index: low water temperatures of the main channel (i.e. mean annual value below 10 °C) and river reaches with no or scarce aquatic and riparian vegetation. In addition to the assessment of river conditions, the ORI could also be applied for monitoring the effects of river restoration actions." 15608. Harabis, F. (2016): High diversity of odonates in post-mining areas: Meta-analysis uncovers potential pitfalls associated with the formation and management of valuable habitats. *Ecological Engineering* 90: 438-446. (in English) ["A growing number of studies indicate high conservation potential of freshwater habitats occurring in post-mining areas. The overall diversity of these habitats depends on many factors, however, even a high diversity may diminish significantly over time. Therefore, it is difficult to identify and understand the importance of key habitat properties for diversity. Here I present analysis of three studies comparing the diversity of dragonflies and damselflies (Odonata). Each study was performed in different coal mining basins within the Czech Republic (a total of 94 sites). In this analysis, I used generalized linear mixed models and several multivariate methods to analyze the effects of a number of environmental characteristics such as depth, bottom substrate or bank slope, reflecting not only the current quality but also the succession and formation of individual pools. The occurrence of overall 14 nationally red listed species indicates the high conservation value of these habitats, while the 40 species found indicate that these areas contribute significantly to regional diversity. Species richness of individual pools was associated with habitat type (spoil heap vs. mine subsidence) and with several habitat variables, in particular the character of vegetation around aquatic habitats. In conclusion, the results indicate that diversity and species composition are significantly influenced by factors reflecting the formation and subsequent succession of pools. Effective conservation management should concentrate primarily on modifying pools' initial properties such as bottom substrate. Subsequent management should then sustain landscape dynamics, which means in particular to sustain minor disturbances that subsequently affect vegetation succession and prevent excessive overgrowing of expansive vegetation, as doing so is promoting the habitat heterogeneity which is essential to high biodiversity in these areas." 15609. Hasenbein, S.; Lawler, S.P.; Geist, J.; Connon, R.E. (2016): A long-term assessment of pesticide mixture effects on aquatic invertebrate communities. *Environmental Toxi-*

cology and Chemistry 35(1): 218-232. (in English) ["To understand the potential effects of pesticide mixtures on aquatic ecosystems, studies that incorporate increased ecological relevance are crucial. Using outdoor mesocosms, the authors examined long-term effects on aquatic invertebrate communities of tertiary mixtures of commonly used pesticides: 2 pyrethroids (permethrin, I-cyhalothrin) and an organophosphate (chlorpyrifos). Application scenarios were based on environmentally relevant concentrations and stepwise increases of lethal concentrations from 10% (LC10) to 50% (LC50) based on laboratory tests on *Hyalella azteca* and *Chironomus dilutus*; repeated applications were meant to generally reflect runoff events in a multiple-grower or homeowner watershed. Pyrethroids rapidly dissipated from the water column, whereas chlorpyrifos was detectable even 6wk after application. Twelve of 15 macroinvertebrate and 10 of 16 zooplankton taxa responded to contaminant exposures. The most sensitive taxa were the snail *Radix* sp., the amphipod *H. azteca*, the water flea *Daphnia magna*, and copepods. Environmentally relevant concentrations had acute effects on *D. magna* and *H. azteca* (occurring 24 h after application), whereas lag times were more pronounced in *Radix* sp. snails and copepods, indicating chronic sublethal responses. Greatest effects on zooplankton communities were observed in environmentally relevant concentration treatments. The results indicate that insecticide mixtures continue to impact natural systems over multiple weeks, even when no longer detectable in water and bound to particles. Combinations of indirect and direct effects caused consequences across multiple trophic levels. ... Summed over the present study period, Zygoptera represented the largest portion of macroinvertebrate abundance (20.9%), followed by the pulmonate snail *Radix* sp. (14.8%) and the amphipod *H. azteca* (13.2%). ... Between the 2 Odonata suborders, the chemical exposure had a greater effect on Anisoptera (positive trend) than Zygoptera. ... Zygoptera was the third most sensitive taxon and displayed a decreased abundance in LC-Chiro in week 2. ... Anisoptera abundance did not significantly deviate from the control over the course of the present study period but displayed a positive trend in all treatments from week 2 to week 5. This trend was not visible in the Odonata abundance, possibly because Anisoptera and Zygoptera responded in opposite directions. ... Zygoptera was the only taxon for which a decrease in emergence was detected." (Authors)] Address: Hasenbein, Simone, Dept of Anatomy, Physiology & Cell Biology, School of Veterinary Medicine, Univ. of California, Davis, California, USA. E-mail: shasenbein@ucdavis.edu

15610. Haug, J.T.; Haug, C.; Garwood, R.J. (2016): Evolution of insect wings and development – new details from Palaeozoic nymphs. *Biological Reviews* 91(1): 53-69. (in English) ["The nymphal stages of Palaeozoic insects differ significantly in morphology from those of their modern counterparts. Morphological details for some previously reported species have recently been called into question. Palaeozoic insect nymphs are important, however – their study could

provide key insights into the evolution of wings, and complete metamorphosis. Here we review past work on these topics and juvenile insects in the fossil record, and then present both novel and previously described nymphs, documented using new imaging methods. Our results demonstrate that some Carboniferous nymphs – those of Palaeodictyopteroidea – possessed movable wing pads and appear to have been able to perform simple flapping flight. It remains unclear whether this feature is ancestral for Pterygota or an autapomorphy of Palaeodictyopteroidea. Further characters of nymphal development which were probably in the ground pattern of Pterygota can be reconstructed. Wing development was very gradual (archimeta-boly). Wing pads did not protrude from the tergum posterolaterally as in most modern nymphs, but laterally, and had well-developed venation. The modern orientation of wing pads and the delay of wing development into later developmental stages (condensation) appears to have evolved several times independently within Pterygota: in Ephemeroptera, Odonoptera, Eumetabola, and probably several times within Polyneoptera. Selective pressure appears to have favoured a more pronounced metamorphosis between the last nymphal and adult stage, ultimately reducing exploitation competition between the two. We caution, however, that the results presented herein remain preliminary, and the reconstructed evolutionary scenario contains gaps and uncertainties. Additional comparative data need to be collected. The present study is thus seen as a starting point for this enterprise." 15611. Hill, M.J.; Sayer, C.D.; Wood, P.J. (2016): When is the best time to sample aquatic macroinvertebrates in ponds for biodiversity assessment? *Environmental Monitoring and Assessment* 188:194: 11 pp. (in English) ["Ponds are sites of high biodiversity and conservation value, yet there is little or no statutory monitoring of them across most of Europe. There are clear and standardised protocols for sampling aquatic macroinvertebrate communities in ponds, but the most suitable time(s) to undertake the survey(s) remains poorly specified. This paper examined the aquatic macroinvertebrate communities from 95 ponds within different land use types over three seasons (spring, summer and autumn) to determine the most appropriate time to undertake sampling to characterise biodiversity. The combined samples from all three seasons provided the most comprehensive record of the aquatic macroinvertebrate taxa recorded within ponds (alpha and gamma diversity). Samples collected during the autumn survey yielded significantly greater macroinvertebrate richness (76 % of the total diversity) than either spring or summer surveys. Macroinvertebrate diversity was greatest during autumn in meadow and agricultural ponds, but taxon richness among forest and urban ponds did not differ significantly temporally. The autumn survey provided the highest measures of richness for Coleoptera, Hemiptera and Odonata. However, richness of the aquatic insect order Trichoptera was highest in spring and

lowest in autumn. The results illustrate that multiple surveys, covering more than one season, provide the most comprehensive representation of macroinvertebrate biodiversity. When sampling can only be undertaken on one occasion, the most appropriate time to undertake surveys to characterise the macroinvertebrate community biodiversity is during autumn, although this may need to be modified if other floral and faunal groups need to be incorporated into the sampling programme." 15613. Hossie, T.J.; Murray, D.L. (2016): Spatial arrangement of prey affects the shape of ratio-dependent functional response in strongly antagonistic predators. *Ecology* 97(4): 834–841. (in English) ["Predators play a key role in shaping natural ecosystems, and understanding the factors that influence a predator's kill rate is central to predicting predator-prey dynamics. While prey density has a well-established effect on predation, it is increasingly apparent that predator density also can critically influence predator kill rates. The effects of both prey and predator density on the functional response will, however, be determined in part by their distribution on the landscape. To examine this complex relationship we experimentally manipulated prey density, predator density, and prey distribution using a tadpole (prey) - dragonfly nymph (predator) system. Predation was strongly ratio-dependent irrespective of prey distribution, but the shape of the functional response changed from hyperbolic to sigmoidal when prey were clumped in space. This sigmoidal functional response reflected a relatively strong negative effect of predator interference on kill rates at low prey: predator ratios when prey were clumped. Prey aggregation also appeared to promote stabilizing density-dependent intra-guild predation in our system. We conclude that systems with highly antagonistic predators and patchily distributed prey are more likely to experience stable dynamics, and that our understanding of the functional response will be improved by research that examines directly the mechanisms generating interference." (Authors)] Address: Hossie, T., Department of Biology, Trent University, Peterborough, Ontario, Canada. E-mail: thossie@trentu.ca

15614. Ilvonen, J.J.; Kaunisto, K.M.; Suhonen, J. (2016): Are sexes equally parasitized in damselflies and dragonflies? *Oikos* 125: 315–325. (in English) ["Parasitism plays an essential part in ecology and evolution of host species and understanding the reasons for differential parasitism within and among hosts species is therefore important. Among the very important factors potentially affecting parasitism is the gender of the host. Here, we studied whether either females

or males are more likely to harbour parasites among odonatan insects, by relying on an extensive literature review and new field data. We collected data on numerous dragonfly and damselfly species and their ectoparasites (water mites) and endoparasites (gregarines) to examine the generality of similarities and differences in prevalence, intensity and maximum number of parasites of male and female hosts. We found three main results. Firstly, most of the odonate host species showed no differences between sexes in either gregarine or water mite prevalence and intensity. The only exception was female damselflies' higher gregarine prevalence and intensity compared to conspecific males. These inequalities in gregarine parasitism may be due to behavioural and physiological differences between conspecific males and females. In comparison, there were no differences in dragonflies between sexes in water mite or gregarine prevalence and intensity. Secondly, damselflies had higher prevalence and intensity levels of both gregarine and water mite parasites compared to dragonflies. Finally, we found a strong species level pattern between female and male parasitism: a certain level of gregarine or water mite parasitism in one sex was matched with a similar parasitism level for the other. This indicates similar exposure and susceptibility to parasites on both sexes. Even though significant differences of parasite levels between the sexes were observed within certain host species, our results strongly suggest that on a general level a more parasitized sex does not exist in the order, Odonata." 15615. Jakob, C.; Poulin, B. (2016): Indirect effects of mosquito control using Bti on dragonflies and damselflies (Odonata) in the Camargue. *Insect Conservation and Diversity* 9: 161-169. (in English) ["(1.) *Bacillus thuringiensis* var. *israelensis* (Bti) has become the most commonly used larvicide to control mosquitoes worldwide. Bti is considered non-toxic to most organisms, except some Diptera such as chironomids, which are a major prey in wetland food webs. (2.) Although Odonata are important predators of mosquitoes and chironomids at the larval and adult stages, no study has ever considered the potential indirect effects of Bti on Odonata abundance through trophic interactions. We addressed this topic in the Camargue where 2500 of the 25 000 ha of mosquito larval biotopes are Bti-sprayed (aqueous solution of VectoBac 12AS at 2.5 L ha⁻¹) whenever mosquito larvae appear in water bodies (i.e. 30–50 aerial treatments overall annually). (3.) Adult Odonata were surveyed along a 100-m line transect in spring, summer and autumn at three control and three treated sites over a 5-year period. (4.) Mean number of species (9.9 vs. 5.2) and of individuals (100 vs. 50) detected per year were significantly higher in control areas compared to Bti-sprayed areas. Bti treatment contributed to 87.3% of the explained variance in Odonata richness, compared to 2.9% for site, 6.8% for year and 3.0% for salinity effects. (5.) These results are coherent with other studies carried out in the same area and time period highlighting a lower abundance of chironomids, and a lower intake of odonates by breeding birds in treated areas.

(6.) We conclude that mosquito control using Bti should be acknowledged as a potential threat to Odonata." (Authors)] Address: Poulin, Brigitte, Tour du Valat, Le Sambuc, 13200 Arles, France. E-mail: poulin@tourduvalat.org

15616. Jeremiason, J.D.; Reiser, T.K.; Weitz, R.A.; Berndt, M.E.; Aiken, G.R. (2016): Aeshnid dragonfly larvae as bio-indicators of methylmercury contamination in aquatic systems impacted by elevated sulfate loading. *Ecotoxicology* 25(3): 456-468. (in English) ["Methylmercury (MeHg) levels in dragonfly larvae and water were measured over two years in aquatic systems impacted to varying degrees by sulfate releases related to iron mining activity. This study examined the impact of elevated sulfate loads on MeHg concentrations and tested the use of MeHg in dragonfly larvae as an indicator of MeHg levels in a range of aquatic systems including 16 river/stream sites and two lakes. MeHg concentrations in aeshnid dragonfly larvae were positively correlated ($R^2 = 0.46$, $p < 0.01$) to peak MeHg concentrations in the dissolved phase for the combined years of 2012 and 2013. This relation was strong in 2012 ($R^2 = 0.85$, $p < 0.01$), but showed no correlation in 2013 ($R^2 = 0.02$, $p > 0.05$). MeHg in dragonfly larvae were not elevated at the highest sulfate sites, but rather the reverse was generally observed. Record rainfall events in 2012 and above average rainfall in 2013 likely delivered the majority of Hg and MeHg to these systems via interflow and activated groundwater flow through reduced sediments. As a result, the impacts of elevated sulfate releases due to mining activities were not apparent in these systems where little of the sulfate is reduced. Lower bioaccumulation factors for MeHg in aeshnid dragonfly larvae were observed with increasing dissolved organic carbon (DOC) concentrations. This finding is consistent with previous studies showing that MeHg in high DOC systems is less bioavailable; an equilibrium model shows that more MeHg being associated with DOC rather than algae at the base of the food chain readily explains the lower bioaccumulation factors." 15617. Jisha Krishnan, E. K.; Sebastian, C. D. (2016): Analysis of phylogenetic status of different *Neurothemis* (Odonata:libellulidae) species using Cytochrome Oxidase I gene sequence. *Global Journal For Research Analysis* 5(3): 85-87. (in English) ["Here we have analysed the phylogenetic relationships of three different species of *Neurothemis* (*tullia*, *intermedia*, *fulvia*) by the partial sequencing of mitochondrial cytochrome oxidase subunit I (COI) gene. Phylogenetic tree constructed by Neighbour joining method proved that *Neurothemis tullia* and *Neurothemis intermedia* are taxonomically more closer and they together formed a single clade in the tree. *Neurothemis fulvia* is sister to this clade but it represents the most diverged species in terms of branch length and nucleotide substitution. Comparison with the retrieved sequences confirmed that it strictly belong to Libellulidae family. The tree also depicted that *Neurothemis* genus is more close to *Orthetrum sabina* than *Diplacodes trivialis*. Hence the study concluded that DNA

barcoding is an invaluable tool for confirming the species identification and to assess the proper phylogenetic relationships." (Authors)] Address: Sebastian, C. D., Molecular Biology Lab., Dept of Zoology, Univ. Calicut, Kerala, India

15618. Jones, D.K.; Hua, J.; Relyea, R.A. (2016): Effects of endosulfan in freshwater pond communities. *Freshwater Science* 35(1): 152-163. (in English) ["Pesticide use has led to ubiquitous contamination of natural habitats that can cause direct and indirect effects on nontarget organisms. Laboratory toxicity tests are valuable for evaluating the direct lethal effects of pesticides, but whether species differences in sensitivity identified from such tests are representative of more natural conditions is unknown. Studies of pesticide effects on communities are needed to understand the indirect effects of pesticides, but many such studies are focused on simplified communities and overlook the contribution of higher trophic levels (i.e., lethal predators), which can have interactive effects with pesticides and may play a large role in influencing community dynamics in contaminated habitats. Much of the research investigating pesticides in communities has focused on organophosphates, carbamates, and pyrethroids, whereas organochlorines are understudied, despite the fact that they can be highly toxic and persist in the environment. We investigated the effect of the organochlorine insecticide endosulfan on aquatic food webs composed of 3 tadpole species, vertebrate and invertebrate predators, zooplankton, and algae. We manipulated endosulfan concentrations (0, 0.2, 3.1, and 27.3 µg/L) and free-ranging predators (adult red-spotted newts [*Notophthalmus viridescens*] and dragonfly larvae [*Anax junius*]). Endosulfan caused direct lethal effects on tadpoles, red-spotted newts, and copepods. Patterns of species sensitivity were consistent with past laboratory experiments. Free-ranging predators caused additive, negative effects on tadpole survival, and affected anuran time to and size at metamorphosis. Our study demonstrated that endosulfan can initiate a wide range of direct and indirect effects on nontarget organisms and interacts additively with lethal predators." (2016): Spatial distribution of benthic macroinvertebrate assemblages in relation to environmental variables in Korean nationwide streams. *Water* 2016, 8(1), 27; doi:10.3390/w8010027: 20 pp. (in English) ["Conserving and enhancing freshwater biodiversity are global issues to ensure ecosystem integrity and sustainability. To meet this, it is critical to understand how the biological assemblages are determined by environmental gradients in different spatial scales. Nevertheless, information on their large-scale environmental relationships remains scarce in Korea. We aimed to understand nationwide spatial distribution patterns of benthic macroinvertebrates and important environmental factors affecting their distribution in 388 streams and rivers across Korea. A total of 340 taxa, be-

longing to 113 families in 23 orders of five phyla, were identified. Assemblage composition in most Korean streams included a few predominant colonizers and a majority of rare taxa. Cluster analysis based on benthic macroinvertebrates classified a total of 720 sampling sites into five clusters according to the pollution levels from fast-flowing less polluted streams with low electrical conductivity to moderately or severely polluted streams with high electrical conductivity and slow water velocity. Canonical correspondence analysis revealed that altitude, water velocity and streambed composition were the most important determinants, rather than watershed and water chemistry variables, for explaining the variation in macroinvertebrate assemblage patterns. The results provide basic information for establishing the conservation and restoration strategies of macroinvertebrate biodiversity against anthropogenic disturbances and developing more confident bio-assessment tools for diagnosing stream ecosystem integrity." (Authors) Odonata are treated at the order level.] Address: Hwang, S.-J., Department of Environmental Health Science, Konkuk University, Seoul 143-701, Korea

15620. Kalkman, V.J.; Gyeltshen, T. (2016): Records of dragonflies from western Bhutan collected in October 2015. IDF-Report 94: 1-15. (in English) ["Distribution data of dragonflies and damselflies from western Bhutan collected during a trip from 10 October 2015 to 22 October 2015 are presented. In total 53 species were recorded of which eleven are new to the country (*Aciagrion pallidum*, *Anisopleura lestoides*, *Megalestes irma*, *Gynacantha incisura*, *Gynacantha khasiaca*, *Gynacanthaeschna sikkima*, *Lamelligomphus risi*, *Somatochlora daviesi*, *Crocothemis erythraea*, *Sympetrum fonscolombii*, *Tholymis tillarga*). Another three species, one *Megalestes* and two *Cephaloeschna*, were not identified to species level but are also addition to the list of species recorded from Bhutan." 15621. Kassner, Z.; Dafni, E.; Ribak, G. (2016): Kinematic compensation for wing loss in flying damselflies. *Journal of Insect Physiology* 85(1): 1-9. (in English) ["Highlights: •*Ischnura elegans* can fly using only three of their wings. •We compare the wingbeat kinematics of four-winged flight with three-winged flight. •In three-winged flight the insects increased wingbeat frequency. •The increase was sufficient to explain compensation for loss in total wing area. •The flapping of the remaining wings changed to allow steady flight. Abstract: Flying insects can tolerate substantial wing wear before their ability to fly is entirely compromised. In order to keep flying with damaged wings, the entire flight apparatus needs to adjust its action to compensate for the reduced aerodynamic force and to balance the asymmetries in area and shape of the damaged wings. While several studies have shown that damaged wings change their flapping kinematics in response to partial loss of wing area, it is unclear how, in insects with four separate wings, the remaining three wings compensate for the loss of a fourth

wing. We used high-speed video of flying *I. elegans* to identify the wingbeat kinematics of the two wing pairs and compared it to the flapping kinematics after one of the hindwings was artificially removed. The insects remained capable of flying and precise maneuvering using only three wings. To compensate for the reduction in lift, they increased flapping frequency by $18\% \pm 15.4\%$ on average. To achieve steady straight flight, the remaining intact hindwing reduced its flapping amplitude while the forewings changed their stroke plane angle so that the forewing of the manipulated side flapped at a shallower stroke plane angle. In addition, the angular position of the stroke reversal points became asymmetrical. When the wingbeat amplitude and frequency of the three wings were used as input in a simple aerodynamic model, the estimation of total aerodynamic force was not significantly different (paired t-test, $p=0.73$) from the force produced by the four wings during normal flight. Thus, the removal of one wing resulted in adjustments of the motions of the remaining three wings, exemplifying the precision and plasticity of coordination between the operational wings. Such coordination is vital for precise maneuvering during normal flight but it also provides the means to maintain flight when some of the wings are severely damaged." 15622. Kastner, F.; Buchwald, R.; Kömer, F.; Marxmeier, U.; Steffens, P.; Winkler, C.-; Jödicke, K.; Mauschering, I. (2016): Wiederansiedlungen als Maßnahmen des Artenschutzes. Die Grüne Mosaikjungfer (*Aeshna viridis*, Odonata) in Niedersachsen und Schleswig-Holstein – ein Beitrag zum Habitatverbund. *Naturschutz und Landschaftsplanung* 48(3): 87-96. (in German, with English summary) ["Reintroduction as a method of species conservation for the Green Hawker (*Aeshna viridis*) – Contribution to habitat networking in Lower Saxony and Schleswig-Holstein - Habitat loss results in a continuous species decline. Options to stop the decline include the improvement of habitat quality or habitat connectivity and in this context also the reintroduction of species to their former range. This paper presents three species conservation projects in Northern Germany aiming to reintroduce and stabilize the rare and protected dragonfly species Green Hawker (*Aeshna viridis*). The dragonfly *A. viridis* is strongly associated with the Water Soldier (*Stratiotes aloides*) as highly specified plant species for oviposition. In two of the projects *S. aloides* was reintroduced in ponds and ditches in order to establish suitable habitats for *A. viridis*. The results showed that the reintroduction of *S. aloides* can be successfully implemented but does not always succeed. Beside the plants the dragonfly species could also be reintroduced indirectly, either as egg or larvae, by transferring it together with the plants. In the third project larvae of *A. viridis* were reintroduced in a second phase after an efficient resettlement of *S. aloides* some years earlier, since the dragonfly had not been successfully transferred together with the plant." 15623. Kautza, A.R.; Sullivan, S.M.P. (2016): The energetic contributions of aquatic primary producers to terrestrial food webs in a mid-size river system. *Ecology* 97(3): 694-705. (in English) ["Rivers are increasingly recognized as providing nutritional subsidies (i.e., energy and nutrients) to adjacent terrestrial food webs via depredation of aquatic organisms (e.g., emergent aquatic insects, crayfish, fish) by terrestrial consumers. However, because these prey organisms assimilate energy from both aquatic (e.g., benthic algae, phytoplankton, aquatic macrophytes) and terrestrial (e.g., riparian leaf detritus) primary producers, river subsidies to terrestrial consumers represent a combination of aquatically- and terrestrially-derived energy. To date, the explicit contribution of energy derived from aquatic primary producers to terrestrial consumers has not been fully explored yet might be expected to be quantitatively important to terrestrial food webs. At 12 reaches along a 185-km segment of the 6th-order Scioto River system (Ohio, USA), we quantified the relative contribution of energy derived from aquatic primary producers to a suite of terrestrial riparian consumers that integrate the adjacent landscape across multiple spatial scales through their foraging activities (tetragnathid spiders, rove beetles, adult coenagrionid damselflies, riparian swallows, and raccoons). We used naturally-abundant stable isotopes (^{13}C and ^{15}N) of periphyton, phytoplankton, macrophytes, and terrestrial vegetation to evaluate the energetic contribution of aquatic primary producers to terrestrial food webs. Shoreline tetragnathid spiders were most reliant on aquatic primary producers (50%), followed by wider-ranging raccoons (48%), damselflies (44%), and riparian swallows (41%). Of the primary producers, phytoplankton (19%) provisioned the greatest nutritional contribution to terrestrial consumers (considered collectively), followed by periphyton (14%) and macrophytes (11%). Our findings provide empirical evidence that aquatic primary producers of large streams and rivers can be a critical nutritional resource for terrestrial food webs. We also show that aquatically-derived nutrition contributes to both shoreline and broader-ranging terrestrial consumers and thus may be an important landscape-scale energetic linkage between rivers and upland habitats." 15626. Kubohara, T.; Ii, H. (2016): Cu, Co and Ni Contamination index for river using river insects and river plants. *International Journal of GEOMATE* 11(26): 2651-2658. (in English) ["Useful species as an index of metal contamination needs a high metal concentration in a contaminated area and low metal concentration in a non-contaminated area. Moreover, it needs a high metal concentration factor. Metal concentrations of moss were high in the Cu mine area (31 to 21,000 and 2 to 200 mg/kg-dry for Cu and Co) and were low in the other areas (2 to 87 and 2 to 33 mg/kg-dry for Cu and Co). Ni concentrations of caddice-worm were high in the serpentinite area (9 to 590 mg/kg-dry) and were low in the other areas (2 to 74 mg/kg-dry). Moss had the highest concentration factor (160,000, 4,600 and 59,000 for Cu, Co and Ni) among river plants. Therefore, it was clarified that moss was useful species for an index of Cu, Co and Ni contamination among river plants based upon its metal concentration and concentration factor. In river insects, metal concentrations of crane fly larva were high in the Cu mine area (50 to 1,400 and 1 to 82 mg/kg-dry for Cu and Co) and were low in the other areas (11 to 130 and 0.7 to 10 mg/kg-dry for Cu and Co). Crane fly larva had the highest concentration factor for Cu (46,000) and also kept high concentration factor for Co (2,700) among river insects. Ni concentrations of caddice-worm were high in the serpentinite area (52 to 220 mg/kg-dry) and were low in the other areas (0.3 to 20 mg/kg-dry). Caddice-worm had the highest Ni concentration factor (22,000) among river insects. Therefore, it was clarified that crane fly larva was useful species for an index of Cu and Co contamination and caddice-worm was useful species for an index of Ni contamination based upon their metal concentrations and concentration factors." (2016): Distribution of benthic macroinvertebrates in a tropical reservoir cascade. *Hydrobiologia* 765: 265-275. (in English) ["The functioning of systems arranged in cascades of reservoirs can be explained by the Cascading Reservoir Continuum

Concept, providing a theoretical framework for addressing ecological processes. In this context, this study tested the following hypotheses: (i) the benthic macroinvertebrate assemblage shows a nested distribution along a reservoir cascade; and (ii) local factors explain the structure of the benthic assemblage in every reservoir along the cascade. Macroinvertebrates play essential role in aquatic systems, especially due to recycling and, in reservoirs, as important links in every food chain. Sampling was conducted quarterly between October 2006 and September 2010 in six reservoirs located in the São Francisco River, Brazil. The benthic macroinvertebrate assemblage showed nested distribution in the reservoirs, indicating that a loss of species occurs along the cascade. Each reservoir presented a different set of variables that explained the distribution of macroinvertebrates, showing the importance of local factors determining the composition and distribution of benthic assemblages in the reservoirs. Therefore, there is a clear interaction between the position of a reservoir along a cascade and the macroinvertebrate assemblages, which indicate the importance of considering this pattern during the decision-making process of constructing new dams on rivers already regulated." 15628. Lee, H.-J.; Johansson, F. (2016): Compensating for a bad start: compensatory growth across life stages in an organism with a complex life cycle. *Canadian Journal of Zoology* 94(1): 41-47. (in English) ["Organisms with a complex life cycle are characterized by a life history shift through metamorphosis, and include organisms such as insects and amphibians. They must optimize their use of resources and behaviour across different life stages in order to maximize their fitness. An interesting question with regard to such life history shifts is whether growth in the juvenile stage can be compensated for in the adult stage. Here we ask whether damselflies are able to compensate for depressed growth during the juvenile aquatic stage in their terrestrial adult stage. Damselflies emerge at a fixed adult body size, but feed during the adult stage and are thus able to gain mass as adults. We performed a mark recapture study in order to answer whether individuals that emerge from metamorphosis with a low mass are able to compensate by subsequent mass gain during the adult stage. Results showed that compensatory mass gain occurred in the adult stage such that small individuals gained more mass than large individuals. We also found that females gained more mass than males. However, individuals that emerged at a low mass still had lower mass as mature adults than individuals that emerged at a high mass, suggesting that compensation was not complete. This suggests that larval ecology and adult fitness are tightly linked and future research should focus more on elucidating the nature of this relationship." 15629. Letsch, H.; Gottsberger, B.; Ware, J.L. (2016): Not going with the flow: a comprehensive time-calibrated phylogeny of dragonflies (Anisoptera: Odonata: Insecta) provides evidence for the role of lentic habitats on diversification. *Molecular Ecology* 25(6): 1340-1353. (in English) ["Ecological diversification of aquatic insects has long been suspected to have been driven by differences in freshwater habitats, which can be classified into flowing (lotic) waters, and standing (lentic) waters. The contrasting characteristics of lotic and lentic freshwater systems imply different ecological constraints on their inhabitants. The ephemeral and discontinuous character of most lentic water bodies may encourage dispersal by lentic species in turn reducing geographical isolation among populations. Hence, speciation probability would be lower in lentic species. Here, we assess the impact of habitat use on diversification patterns in dragonflies (Anisoptera: Odonata). Based on eight nuclear and mitochondrial genes, we inferred species diversification with a model-based evolutionary framework, to account for rate variation through time and among lineages, and to estimate the impact of larval habitat on the potentially non-random diversification among anisopteran groups. Ancestral state reconstruction revealed lotic fresh water systems as their original primary habitat, while lentic waters have been colonised independently in Aeshnidae, Corduliidae and Libellulidae. Furthermore, our results indicate a positive correlation of speciation and lentic habitat colonisation by dragonflies: speciation rates increased in lentic Aeshnidae and Libellulidae, whereas they remain mostly uniform among lotic groups. This contradicts the hypothesis of inherently lower speciation in lentic groups and suggests species with larger ranges are more likely to diversify, perhaps due to higher probability of larger areas being dissected by geographical barriers. Furthermore, larger range sizes may comprise more habitat types, which could also promote speciation by providing additional niches, allowing the coexistence of emerging species." 15631. Macedo, D.R.; Hughes, R.M.; Ferreira, W.R.; Firmiano, K.R.; R.O. Silva, D.R.O.; Ligeiro, R.; Kaufmann, P.R.; Callisto, M. (2016): Development of a benthic macroinvertebrate multimetric index (MMI) for Neotropical Savanna headwater streams. *Ecological Indicators* 64: 132-141. (in English) ["Highlights: •We tested four macroinvertebrate multimetric indices (MMIs) for the Cerrado biome. •We used a statistical criterion for identifying least- and most-disturbed sites. •The best-performing MMI had landscape-adjusted and PCA-selected metrics. •Our MMI is sensitive to anthropogenic pressures at local- and catchment-scales. Abstract: Assessing the ecological impacts of anthropogenic pressures is a key task in environmental management. Multimetric indices (MMIs), based on aquatic assemblage responses to anthropogenic pressures, have been used increasingly throughout the world. The MMI approach is a low-cost, rapid field method that produces an aquatic condition index that responds precisely to anthropogenic pressures, making it useful for conservation and environmental management. We developed four candidate MMIs based on benthic macroinvertebrate assemblages sampled at 40 randomly selected sites to assess the environmental condition of streams upstream of a hydroelectric power plant in the Brazilian Neotropical Savanna biome. Those MMIs were built from landscape-adjusted and unadjusted biological metrics as well as two alternative ways of choosing metrics. The alternative MMIs performances were tested by comparing their precision to distinguish least-disturbed areas, responsiveness to discriminate least- and most-disturbed areas, and sensitivity to anthropogenic pressures at catchment and local scales. The best performing MMI had landscape-adjusted metrics and was produced through use of principal component analysis for metric selection. It included 4 metrics: Ephemeroptera richness, average tolerance score per taxon, percentage of predator individuals, and percentage of Odonata individuals adjusted by elevation. This index discriminated well the anthropogenic pressures at local- and catchment-scales, and at both scales simultaneously, as indicated by an integrated disturbance index. Our methodological development included statistical criteria for identifying least- and most-disturbed sites, calibrating for natural landscape variability, and use of non-redundant metrics. Therefore, we expect it will provide a model for environmental assessment of water resources elsewhere in Brazil and in other nations." ford R.J.; Ivanova, E.P. (2016): The nature of inherent bactericidal activity: insights from the nanotopology of three species of dragonfly. *Nanoscale* 8: 6527-6534. (in English) ["While insect wings are widely recognised as multi-functional, recent work showed that this extends to extensive bactericidal activity brought about by cell deformation and lysis on the wing nanotopology. We now quantitatively show that subtle changes to this topography result in substantial changes in bactericidal activity able span an order of magnitude. Notably, the chemical composition of the lipid nanopillars was seen by XPS and synchrotron FTIR microspectroscopy to be similar across these activity differences. Modelling the interaction between bacterial cells and the wing surface lipids of 3 species of dragonflies (*Hemianax papuensis*, *Austroaeschna multipunctata*, *Diplacodes bipunctata*), that inhabit similar environments but with distinctly different behavioural repertoires, provided the relationship between surface structure and antibacterial functionality. In doing so, these principal behavioural patterns correlated with the demands for antimicrobial efficiency dictated by differences in their foraging strategies. This work now reveals a new feature in the design elegance of natural multi-functional surfaces as well providing insights into bactericidal mechanism underlying inherently antimicrobial materials, while suggesting that nanotopology is related to evolutionary development of a species through the demands of its behavioural repertoire. The underlying relationship between the processes of wetting, adhesion and capillarity of the lipid nanopillars and bactericidal efficiency suggests new prospects for purely mechano-responsive antibacterial surfaces." 15633. Mair, L.; Ruete, A. (2016): Explaining spatial variation in the recording effort of citizen science data across multiple taxa. *PLoS ONE* 11(1): e0147796. doi:10.1371/journal.pone.0147796: 13 pp. (in English) ["The collation of citizen science data in open-access biodiversity databases makes temporally and spatially extensive species' observation data available to a wide range of users. Such data are an invaluable resource but contain inherent limitations, such as sampling bias in favour of recorder distribution, lack of survey effort assessment, and lack of coverage of the distribution of all organisms. Any technical assessment, monitoring program or scientific research applying citizen science data should therefore include an evaluation of the uncertainty of its results. We use 'ignorance' scores, i.e. spatially explicit indices of sampling bias across a study region, to further understand spatial patterns of observation behaviour for 13 reference taxonomic groups. The data is based on voluntary observations made in Sweden between 2000 and 2014. We compared the effect of six geographical variables (elevation, steepness, population density, log population density, road density and footpath density) on the ignorance scores of each group. We found substantial variation among taxonomic groups in the relative importance of different geographic variables for explaining ignorance scores.

In general, road access and logged population density were consistently important variables explaining bias in sampling effort, indicating that access at a landscape-scale facilitates voluntary reporting by citizen scientists. Also, small increases in population density can produce a substantial reduction in ignorance score. However the between-taxa variation in the importance of geographic variables for explaining ignorance scores demonstrated that different taxa suffer from different spatial biases. We suggest that conservationists and researchers should use ignorance scores to acknowledge uncertainty in their analyses and conclusions, because they may simultaneously include many correlated variables that are difficult to disentangle." (Authors) The data set includes Odonata.] Address: Mair, Louise, Species Information Centre, Swedish University of Agricultural Sciences (SLU), P.O. 7007, 750 07 Uppsala, Sweden. 15634. Marinov, M.; Amaya-Perilla, C.; Holwell, G.I.; Varsani, A.; Van Bysterveldt, K.; Kraberger, S.; Stainton, D.; Dayaram, A.; Curtis, N.; Cruickshank, R.H.; Paterson, A. (2016): Geometric morphometrics and molecular systematics of *Xanthocnemis sobrina* (McLachlan, 1873) (Odonata: Coenagrionidae) and comparison to its congeners. *Zootaxa* 4078(1): 84-120. (in English) ["The taxonomy of the damselfly genus *Xanthocnemis* is revised, with particular focus on populations inhabiting the North Island of New Zealand. Earlier studies revealed two species: *X. sobrina*, restricted to cool, shaded streams in kauri forests and other forested areas, and *X. zealandica*, a common species throughout New Zealand except the Chatham and subantarctic islands. A field study encompassing aquatic habitats throughout the whole North Island was carried out to establish the relationship between morphological variation (body size and various morphological traits over the entire body) observed by previous researchers with ecological conditions and/or geographical location. The main aim was to propose reliable diagnostic features that could be used in future studies. Morphological and molecular variation was assessed. Morphological examination included assigning landmarks for all body parts corresponding to the external morphological features that are usually used in Odonata taxonomy. Molecular analysis targeted fragments of the 28S and 16S rRNA genes. Congruence was sought between both types of data, statistical support for two morphological types previously described as different species and a maximum likelihood phylogenetic tree in conjunction with a pairwise genetic distance matrix constructed from the DNA sequences obtained from the sampled specimens. Geometric morphometrics revealed statistically significant differentiation between specimens identified as *X. zealandica* and *X. sobrina* for four traits: (1) dorsal view of the head for both sexes as well as male appendages from (2) dorsal, (3) ventral and (4) lateral views. Wings appeared different when analysed for males only. Molecular analysis, however, grouped all specimens into a single undifferentiated cluster with very low mean pairwise distance (<0.01) between them showing almost no variation at the molecular level among the sampled populations on the North Island. Therefore, an additional

analysis of the mitochondrial cytochrome c-oxidase I gene was carried out comparing randomly selected North Island specimens to *Xanthocnemis* specimens targeted in other molecular studies (Nolan et al. 2007, Amaya-Perilla et al. 2014). The analysis of the COI gene confirmed that all North and South Island isolates of *Xanthocnemis* cluster together in a well-supported clade with pairwise identity >96% and ~93% pairwise identity with *X. tuanuii* sequences obtained from the Chatham Island specimens. A careful investigation of the thin plate spline deformations generated for the geometric morphometric landmarks showed that the significant variations in the appendages of the *Xanthocnemis* specimens appeared to be the result of size, rather than shape, differences. Therefore, *X. sobrina* is proposed as a synonym of *X. zealandica*. Recently Amaya-Perilla et al. (2014) synonymised *X. sinclairi* with *X. zealandica* and confirmed the status of the Chatham Island *X. tuanuii* as a distinct species. It is therefore proposed that the genus *Xanthocnemis* consists of two species only: *zealandica* occurring all over the North, South and Stewart Islands, and *tuanuii*, endemic to Chatham and Pitt islands. Considering several statistical tests involving body measurements and ecological variables recorded during the field study, as well as various discussion points from similar studies of other species of Odonata, two alternative hypotheses are proposed for future testing. The first hypothesis synonymises *X. sobrina* with *X. zealandica* and suggests a possible explanation for the evolution of the two morphological traits that have previously been considered diagnostic for these species. The second hypothesis suggests that as typical *X. sobrina* were not sampled during this study this could represent a species that is now extinct, unless future studies prove it otherwise." 15635. Martínez, A.; Larrañaga, A.; Miguélez, A.; Yvon-Durocher, G.; Pozo, J. (2016): Land use change affects macroinvertebrate community size spectrum in streams: the case of *Pinus radiata* plantations. *Freshwater Biology* 61: 69-79. (in English) ["(1.) In low-order forested streams, catchment-scale land-use modifications to vegetation can affect energy inputs into streams and trophic interactions within these donor-controlled food webs. (2.) We examined the effects of *Pinus radiata* plantations on the intercept and slope of the size spectrum (the relationship between log-mass and log-density) of macroinvertebrate communities in low-order forested streams. We compared three streams draining pine plantations with three draining native deciduous forests, all without significant differences in water physicochemical characteristics. (3.) While size spectrum intercept was similar between the two stream types, the slope of the size spectrum was shallower in pine than in deciduous streams based on a decline in the density of the smaller individuals. (4.) The shredder feeding guild showed the largest changes, with a significant reduction in their total density and, specifically, in the density of the smaller individuals from the deciduous to the pine streams. This alteration is

explained by the change in very specialist shredders, such as plecopterans and trichopterans, but not in those with highly mobile crustaceans or more generalist dipterans. (5.) The effect detected for shredders might have scaled up to higher trophic levels as the density of invertebrate predators (small and big) was lower in streams under pine, suggesting a response to prey limitation. 6. These results indicate that the change of in-stream resource quality arising from the replacement of deciduous vegetation by pine plantations can trigger size-specific responses of macroinvertebrates and target specialised feeding guilds such as shredders, and can elicit a bottom-up reaction in the organisation of food webs." (Authors) Boyeria, Calopteryx and Gomphus settled only in deciduous streams, while Cordulegaster inhabitate deciduous as pine streams as well.] Address: Martínez, A., Laboratory of Stream Ecology, Department of Plant Biology and Ecology, University of the Basque Country, P.O. 15636. Melfi, J.; Leonardo, A.; Wang, J. (2016): Recovery methods of the dragonfly from irregular initial conditions. *Bulletin of the American Physical Society*. Abstract: R41.00013: (in English) [Verbatim: We release dragonflies from a magnetic tether in a wide range of initial orientations, which results in them utilizing multiple methods to regain their typical flight orientation. Special focus is placed on dropping them while upside down, as the recovery method used is a purely rolling motion. Filming this stereotypical motion with a trio of high speed cameras at 4000 fps, we capture detailed body and wing kinematics data to determine how the dragonfly generates this motion. By replaying the flights within a computer simulation, we can isolate the significant changes to wing kinematics, and find that it is an asymmetry in the wing pitch which generates the roll. Further investigation demonstrates that this choice is highly dependent upon the state of the dragonfly, and as such our results indicate the dragonfly both tracks its current state, and changes its mid-flight control mechanisms accordingly.] Address: Wang, Z. 15640. Moskowit, D.P. (2016): The life history, behavior and conservation of the Tiger Spiketail dragonfly (*Cordulegaster erronea* Hagen) in New Jersey. Ph.D. thesis, Graduate School - New Brunswick, Rutgers, The State University of New Jersey: VIII + 128 pp. (in English) ["This dissertation explores the life history and behaviour of *C. erronea* and provides recommendations for the conservation of the species. Like most species in the genus *Cordulegaster* and the family *Cordulegastridae*, the Tiger Spiketail is geographically restricted, patchily distributed with its range, and a habitat specialist in habitats susceptible to disturbance. Most *Cordulegastridae* species are also of conservation concern and *C. erronea* is no exception. However, many aspects of the life history of *C. erronea* and many other *Cordulegastridae* are poorly understood, complicating conservation strategies. In this dissertation, I report the results of my research on *C. erronea* in New Jersey. The research to investigate life history and behaviour included: larval and

exuvial sampling; radio-telemetry studies; marking-resighting studies; habitat analyses; observations of ovipositing females and patrolling males, and the presentation of models and insects to patrolling males. The research reports: the first use of radio-telemetry for the species; the first observations of mating; the first comprehensive report and analysis of larval site emergence site selection; the triggering mechanisms for male recognition of females; adult and larval habitat use, and many other life history and behavioural aspects of the species. The dissertation also provides recommendations for conservation strategies that maybe useful for protecting the Tiger Spiketail and other *Cordulegastridae* species." (Author)] Address: not stated

15641. Munguía-Steyer, R.; Córdoba-Aguilar, A.; Maya-García, J.S. (2016): Rubyspot territorial damselflies behave as "Nasty Neighbors". *Journal of Insect Behavior* 29(2): 143-152. (in English) ["Two mutually-excluding hypotheses explain the intensity of aggression between neighbours and their non-neighbours in territorial animals. On one hand, the "dear enemy" hypothesis predicts that territorial animals should be more tolerant towards their neighbours than towards non-neighbours. Conversely, the "nasty neighbor" hypothesis predicts increased aggression towards neighbours than non-neighbours. These different situations depend on who is more likely to be a real competitor, either a neighbour or a non-neighbour, and the intensity of resource competition. Male damselfly of *Hetaerina vulnerata* defend riverine, mating territories that is the main way to have access to females. These territories are not fixed and so males continuously defend them especially against neighbours. Given this, we tested whether the nasty neighbour principle operates in this species. We monitored a population during an entire mating season, and recorded duration of aggressive behaviours. As a key prediction of the nasty neighbour hypothesis, we expected that such behaviours last for longer when encountering a conspecific neighbour than a conspecific non-neighbour. We also predicted that such duration should be date-dependent as territorial competition could increase in the middle of the season when male density is at its highest. Our results corroborated that aggressive behaviours lasted longer against a neighbour male than a non-neighbour male but there was not effect of date. Thus, neighbours may pose a greater risk and may be a strong selective force than non-neighbours in terms of resource competition. Since neighbour males are continuously trying to widen their territory boundaries (a situation that has been also found in other study systems), an owner male may not even need to recognize his neighbours to fight back." 15642. Mutlu, O.; Gumuslu, E.; Kokturk, S.; Ulak, G.; Akar, F.; Erden, F.; Kaya, H.; Tanyeri, P. (2016): Effects of chronic administration of adipokinetic and hypertrehalosemic hormone on animal behavior, BDNF, and CREB expression in

the hippocampus and neurogenesis in mice. *Fundamental & Clinical Pharmacology* 30(1): 4-13. (in English) ["Neurosecretory cells in corpus cardiacum of insects synthesize a set of hormones that are called adipokinetic, hypertrehalosaemic or hyperprolinaemic, depending on insect in question. This study investigated effects of chronic administration of *Anax imperator* adipokinetic hormone (Ani-AKH), *Libellula auripennis* adipokinetic hormone (Lia-AKH), and *Phormia-Terra* hypertrehalosaemic hormone (Pht-HrTH) on depression, anxiety, analgesy, locomotion in forced swimming (FST), elevated plus-maze (EPM), hot plate, and locomotor activity tests. Ani-AKH (1 and 2 mg/kg), Lia-AKH (1 and 2 mg/kg), and Pht-HrTH (1 and 2 mg/kg) had antidepressant effects in forced swimming test. Lia-AKH (2 mg/kg) and Pht-HrTH (1 and 2 mg/kg) had anxiolytic effects when given chronically in elevated plus-maze test. Ani-AKH (1 and 2 mg/kg) and Pht-HrTH (2 mg/kg) had antinociceptive effects in hot plate test in male balb-c mice. Ani-AKH (2 mg/kg), Lia-AKH (1 and 2 mg/kg), and Pht-HrTH had locomotion-enhancing effects in locomotor activity test in male balb-c mice. Drug treatment significantly increased brain-derived neurotrophic factor (BDNF) and cyclic adenosine monophosphate (cAMP) response element binding protein (CREB) gene expression levels compared to control levels. Pht-HrTH and Ani-AKH groups had significantly increased numbers of BrdU-labeled cells, while neurodegeneration was lower in the Pht-HrTH group. Our study showed that AKH/RPCH family peptides may be used in treatment of psychiatric illness such as depression and anxiety, in treatment of pain and in diseases related to locomotion system. AKH/RPCH family peptides increase neurotrophic factors in brain and have potential proliferative and neuroprotective effects in hippocampal neurogenesis and neurodegeneration." 15643. Naka, H.; Hashimoto, H. (2016): The effect of passive deformation of dragonfly wing on aerodynamic characteristics. *Transactions of the JSME* 82(833): 14 pp. (in Japanese, with English summary) ["Dragonflies can perform both of gliding and flapping flight and have high maneuverability in spite of small-size. The aim of this study is to develop Micro Air Vehicle (MAV) based on the flight of dragonfly. The characteristics of wings are very important for development of MAV. Dragonfly wing is easy to be passively deformed in the tip side from the nodus in flapping flight, and thereby, aerodynamic force is generated effectively. In this study, the effect of passive deformation of wing on aerodynamic force was investigated using fluid-structure interaction analysis to develop the artificial wing suitable for dragonfly-like MAV. In this study, aerodynamic characteristics of wings in the gliding flight and aerodynamic force generated in flapping flight are numerically analyzed. In this analysis, nodus wing models, which can deform passively, and rigid wing model, which cannot deform, are used. Nodus wing model imitates the nodus structure; the tip side of this model is free to rotate around leading edge. As a result of gliding flight, the lift coefficient of the nodus wing was lower in low-

angle of attack and was higher in high-angle of attack, compared to rigid wing. Moreover, the more flexible wings are, the more change. The gliding flight is low-angle of attack usually. Therefore, flexible wing is less suitable for the gliding flight than inflexible wing. As a result of flapping flight, the nodus wing made drag force generated during down stroke lower compared with the rigid wing. However, thrust forces generated during up stroke in both wings were the same. Therefore, flexible wings are more suitable for the flapping flight than inflexible wing. The wings of dragonfly-like MAV need to appropriate level of flexibility to upgrade the performance in both case of gliding and flapping flight." 15644. Nayak, A.K.; Roy, U.S. (2016): An observation on the Odonata fauna of the Asansol-Durgapur Industrial Area, Burdwan, West Bengal, India. *Journal of Threatened Taxa* 8(2): 8503-8517. (in English) ["The present investigation was undertaken as a pilot study to examine the diversity, occurrence and distribution pattern of Odonata from the selected study sites of the Asansol-Durgapur industrial area of Burdwan District of West Bengal, India from January 2012 to December 2015. A combination of direct search and opportunistic sighting methods were applied to record 57 different Odonata species (38 dragonflies and 19 damselflies). Among the dragonflies the most diverse family was Libellulidae represented by 36 species while among damselflies Coenagrionidae was the most diverse family represented by 16 species. In spite of the Asansol-Durgapur region being an industrial urban area, the present study revealed a handsome diversity of odonates. A suitable geographic location, favourable climatic conditions, heterogeneous habitat types that included ponds, wetlands, riverbeds, grasslands and agricultural lands along with the presence of appropriate vegetation provided a comfortable shelter for Odonata species to flourish in this ecoregion. All the odonates noted in the present study belong to the Least Concerned category as designated by IUCN." 15655. Piria, M.; Jakšić, G.; Jakovlic, I.; Treer, T. (2016): Dietary habits of invasive Ponto-Caspian gobies in the Croatian part of the Danube River basin and their potential impact on benthic fish communities. *Science of The Total Environment* 540: 386-395. (in English) ["Highlights: •Dietary habits and impacts of invasive P-C gobies on other fish were studied. •Monkey and round goby preferred Trichoptera, Megaloptera and Coleoptera. •Bighead goby preferred Trichoptera, Gammarus and Pisces. •No negative impacts of the most abundant, monkey goby, on native fish populations. •Round goby negatively impacts native zingel, and bighead goby - chub populations. Abstract: Invasive Ponto-Caspian (P-C1) gobies have recently caused dramatic changes in fish assemblage structures throughout the Danube basin. While their presence in the Croatian part of the basin has been noted and distribution studied, their dietary habits and impacts on native fish communities have, until now, been unknown. In 2011, 17 locations in the Sava River Basin were sampled for fish and 15 for benthic invertebrates. Fish population monitoring data, available for nine

seasons (2003–2006 and 2010–2014) and 12 locations, were used to analyse the impacts of P-C gobies on benthic fish abundance. Gut content analysis indicates that the monkey goby *Neogobius fluviatilis* diet is very diverse, but dominated by Trichoptera, Chironomidae, Bivalvia and Odonata. The diet overlaps considerably with the round goby *Neogobius melanostomus* diet, although Gastropoda are dominant in the latter's diet. Small fish and *Gammarus* sp. dominate the bighead goby *Ponticola kessleri* diet. Comparison of gut content with the prey available in the environment indicates that monkey and round gobies exhibit preference for Trichoptera, Megaloptera and Coleoptera, and bighead goby for Trichoptera, *Gammarus* sp. and Pisces. P-C gobies in the Sava River are spreading upstream, towards the reaches with lower fish diversity. Analyses indicate potentially positive impacts of P-C gobies' presence on some fish populations: round and bighead goby on Balkan golden loach *Sabanejewia balcanica* and monkey goby on common carp *Cyprinus carpio*, crucian carp *Carassius carassius*, burbot *Lota lota* and Balkan loach *Cobitis elongata*. However, there are also indications that bighead and round goby could adversely impact the native chub *Squalius cephalus* and zingel *Zingel zingel* populations, respectively. As P-C gobies are still in the expansionary period of invasion and the ecosystem still adapting to new circumstances, continued monitoring of fish population dynamics in the Sava basin is needed to determine the outcome and impacts of this invasion." 15656. Polo-Cavia, N.; Burraco, P.; Gomez-Mestre, I. (2016): Low levels of chemical anthropogenic pollution may threaten amphibians by impairing predator recognition. *Aquatic Toxicology* 172: 30-35. (in English) ["Highlights: •Humic acid and ammonium nitrate impair responses of tadpoles to predator cues. •Even low concentrations of pollutants increase predation risk of tadpoles. •Sublethal pollution may contribute to amphibian declines by disrupting predator recognition. Abstract: Recent studies suggest that direct mortality and physiological effects caused by pollutants are major contributing factors to global amphibian decline. However, even sublethal concentrations of pollutants could be harmful if they combined with other factors to cause high mortality in amphibians. Here we show that sublethal concentrations of pollutants can disrupt the ability of amphibian larvae to recognize predators, hence increasing their risk of predation. This effect is indeed much more important since very low amounts of pollutants are ubiquitous, and environmental efforts are mostly directed towards preventing lethal spills. We analyzed the effects of two common contaminants (humic acid and ammonium nitrate) on the ability of tadpoles of the western spadefoot toad (*Pelobates cultripes*) to recognize chemical cues from a common predator, nymphs of the dragonfly *Anax imperator*. We compared the swimming activity of tadpoles in the presence and absence of water-borne chemical cues from dragonflies at

different concentrations of humic acid and ammonium nitrate. Tadpoles reduced swimming activity in response to predator cues in the absence of pollutants, whereas they remained unresponsive to these cues when either humic acid or ammonium nitrate was added to the water, even at low concentrations. Moreover, changes in tadpole activity associated with the pollutants themselves were non-significant, indicating no toxic effect. Alteration of the natural chemical environment of aquatic systems by pollutants may be an important contributing cause for declines in amphibian populations, even at sublethal concentrations." (2016): Cyclicity of long-term population dynamics in damselflies of the genus *Coenagrion* (Odonata, Zygoptera) in the Lake Chany basin. *Russian Journal of Ecology* 47(1): 74-81. (in English) ["The cyclicity of population dynamics of abundance has been analyzed in sympatric adult populations of three odonate species monitored for long time (1980–2010) in the Lake Chany basin (Western Siberia). The spectra of odonate population dynamics have been constructed for the first time and shown to be species-specific: each species has its own population cycles, and if the cycles are similar, interspecific differences manifest themselves in the relative power of these cycles. These differences provide for separation of species in time, reducing the stress of competition between them. The population rhythms of all studied species show synchronicity with natural rhythms that are important to them, such as fluctuations of climatic parameters (2–3 year cycles) and hydrological parameters of Lake Chany (2–4-year cycles)."] (Authors)] Address: Popova, Olga, Institute of Systematics and Ecology of Animals, Siberian Branch, Russian Academy of Sciences, ul. 15658. Rajabi, H.; Rezasefat, M.; Darvizeh, A.; Dirks, J.-H.; Eshghi, S.; Shafiei, A.; Mirzababaie Mostofi, T.; Gorb, S.N. (2016): A comparative study of the effects of constructional elements on the mechanical behaviour of dragonfly wings. *Applied Physics A* 122:19: 13 pp. (in English) ["Although wings of insects show a large variation in morphology, they are all made from a network of irregular veins interconnected through membranous areas. Depending on their shape, size, and position, wing veins are usually divided into three different groups: longitudinal veins, cross-veins and ambient veins. The veins together with the membrane and some other elements such as spines, nodus and pterostigma can be considered as the wing's "constructional elements". In spite of rather extensive literature on dragonfly wing structure, the role of each of these elements in determining the wing's function remains mostly unknown. As this question is difficult to answer in vivo using biomechanical experiments on actual wings, this study was undertaken to reveal the effects of the constructional elements on the me-

chanical behaviour of dragonfly wings by applying numerical simulations. An image processing technique was used to develop 12 finite element models of the insect wings with different constructional elements. The mechanical behaviour of these models was then simulated under normal and shear stresses due to tension, bending and torsion. A free vibration analysis was also performed to determine the resonant frequencies and the mode shapes of the models. For the first time, a quantitative comparison was carried out between the mechanical effects selectively caused by different elements. Our results suggest that the complex interactions of veins, membranes and corrugations may considerably affect the dynamic deformation of the insect wings during flight." 15659. Rajabi, H.; Ghoroubi, N.; Darvizeh, A.; Appel, E.; Gorb, S.N. (2016): Effects of multiple vein microjoints on the mechanical behaviour of dragonfly wings: numerical modelling. *R. Soc. open sci.* 3: 150610. <http://dx.doi.org/10.1098/rsos.150610>: 16 pp. (in English) ["Dragonfly wings are known as biological composites with high morphological complexity. They mainly consist of a network of rigid veins and flexible membranes, and enable insects to perform various flight manoeuvres. Although several studies have been done on the aerodynamic performance of Odonata wings and the mechanisms involved in their deformations, little is known about the influence of vein joints on the passive deformability of the wings in flight. In this article, we present the first three-dimensional finite-element models of five different vein joint combinations observed in Odonata wings. The results from the analysis of the models subjected to uniform pressures on their dorsal and ventral surfaces indicate the influence of spike-associated vein joints on the dorso-ventral asymmetry of wing deformation. Our study also supports the idea that a single vein joint may result in different angular deformations when it is surrounded by different joint types. The developed numerical models also enabled us to simulate the camber formation and stress distribution in the models. The computational data further provide deeper insights into the functional role of resilin patches and spikes in vein joint structures. This study might help to more realistically model the complex structure of insect wings in order to design more efficient bioinspired micro-air vehicles in future." (2016): Effect of microstructure on the mechanical and damping behaviour of dragonfly wing veins. *Royal Society Open Science* 3: 160006. <http://dx.doi.org/10.1098/rsos.160006>: 12 pp. (in English) ["Insect wing veins are biological composites of chitin and protein arranged in a complex lamellar configuration. Although these hierarchical structures are found in many 'venous wings' of insects, very

little is known about their physical and mechanical characteristics. For the first time, we carried out a systematic comparative study to gain a better understanding of the influence of microstructure on the mechanical characteristics and damping behaviour of the veins. Morphological data have been used to develop a series of three-dimensional numerical models with different material properties and geometries. Finite-element analysis has been employed to simulate the mechanical response of the models under different loading conditions. The modelling strategy used in this study enabled us to determine the effects selectively induced by resilin, friction between layers, shape of the cross section, material composition and layered structure on the stiffness and damping characteristics of wing veins. Numerical simulations suggest that although the presence of the resilin-dominated endocuticle layer results in a much higher flexibility of wing veins, the dumbbell-shaped cross section increases their bending rigidity. Our study further shows that the rubber-like cuticle, friction between layers and material gradient-based design contribute to the higher damping capacity of veins. The results of this study can serve as a reference for the design of novel bioinspired composite structures." 15661. Razeng, E.; Moran-Ordóñez, A.; Brim Box, J.; Thompson, R.; Davies, J.; Sunnucks, P. (2016): A potential role for overland dispersal in shaping aquatic invertebrate communities in arid regions. *Freshwater Biology* 61: 745-757. (in English) [Australia, "(1.) Traditionally, dispersal of aquatic invertebrates has been thought to be very closely associated with river network structure, despite many species being capable of active or passive dispersal across the terrestrial matrix. However, recent studies of both population genetics and community structure from dryland regions indicate that aquatic species commonly disperse across catchments, implying that movement away from streams is more common than originally thought. This study investigated how aquatic invertebrate metacommunity structure in central Australia is influenced by interactions between species' dispersal traits, dispersal routes and local environmental conditions. (2.) We sampled community composition in 16 perennial and long-term inundated freshwater habitats in central Australia. Aquatic invertebrate taxa were allocated to one of four dispersal trait groups: obligate aquatic, passive aerial, weak flying and strong flying. We then used Mantel tests to examine correlations between trait group community dissimilarities, and four isolation models representing (i) local environmental conditions, (ii) geographical distances, (iii) landscape resistances restricted to river networks and (iv) landscape resistances incorporating overland dispersal 'conduits'. (3.) We found that the community composition of aquatic invertebrates in three of four dispersal trait groups, and all traits combined, was influenced primarily by topographic connectivity via overland dispersal conduits. (4.) Our results suggest that rainfall events and their effect on the landscape as a whole, rather than river flow during these

events, shape aquatic invertebrate metacommunity structure in central Australia. This study provides further support for the importance of overland dispersal conduits to aquatic invertebrates, particularly in arid environments with irregular rainfall." 15663. Rodrigues, M.E.; Roque, F.; Ochoa Quintero, J.M.; Penad, J.C.; Caribé de Sousa, D.; De Marco Junior, P. (2016): Nonlinear responses in damselfly community along a gradient of habitat loss in a savanna landscape. *Biological Conservation* 194: 113-120. (in English) ["Highlights: •We evaluated thresholds for damselflies in riparian zones in a savanna landscape. •We sampled 98 streams located in the Pantanal plateau, Brazil. •We used Threshold Indicator Taxa Analysis — TITAN and segmented regression analysis. •We found weak evidence of a threshold between 40 and 60% native vegetation loss. •Maintaining habitat loss above the "zone of increasing risk of impact" should be priority for conservation planners. Abstract: Riparian zones are among the most threatened natural ecosystems, being greatly affected by land use changes across the world. Working in a savanna landscape in the Central-West region of Brazil, we assessed the responses of damselfly communities to changes on native vegetation extent in riparian zones. We sampled damselflies around 98 streams in a continuous gradient of native vegetation loss (0 to 100%). We used the Threshold Indicator Taxa Analysis (TITAN) to test whether the damselfly community showed nonlinear responses related to native vegetation loss within buffers of 250 m radius. We collected 1245 individuals of damselflies, representing 31 species. The TITAN identified 16 species with a significant response: 11 species with negative indicators (Z⁻) and five as positive indicators (Z⁺) in relation to native vegetation loss. Six species showed evidence of nonlinear response (Z⁻), at sites with native vegetation loss between 40% and 60%. We also used segmented regression analysis with species richness, which showed weak evidence of a threshold located at 54% of native vegetation loss. Differently of previous studies with other taxonomic groups in forested environments, our results indicate that the variability around the threshold is higher. Under a precaution perspective and given current levels of vegetation loss around streams where the risk of losing species is higher, we reinforce the importance of appropriate landscape management strategies. In order to effectively conserve biodiversity in aquatic-and-terrestrial environments, the native vegetation loss within pastures and agriculture landscapes, should be above the "zone of increasing risk of impact" level. According to the current Brazilian Forest Act, riparian forest of at least 30 m wide must

be preserved along both sides of each watercourse. In our study 30 m vegetation wide represents only 10% of the 250 m buffer area. It implies that the current Brazilian Forest Act does not preserve the Cerrado's riparian vegetation and its associated aquatic biodiversity, since the amount of native vegetation loss is below the "zone of increasing risk of impact" we detected for damselflies in evaluated landscapes." (2016): Feeding behaviour, predatory functional responses and trophic interactions of the invasive Chinese mitten crab (*Eriocheir sinensis*) and signal crayfish (*Pacifastacus leniusculus*). *Freshwater Biology* 61(4): 426-443. (in English) ["(1.) Freshwaters are subject to particularly high rates of species introductions; hence, invaders increasingly co-occur and may interact to enhance impacts on ecosystem structure and function. As trophic interactions are a key mechanism by which invaders influence communities, we used a combination of approaches to investigate the feeding preferences and community impacts of two globally invasive large benthic decapods that co-occur in freshwaters: the signal crayfish (*Pacifastacus leniusculus*) and Chinese mitten crab (*Eriocheir sinensis*). (2.) In laboratory preference tests, both consumed similar food items, including chironomids, isopods and the eggs of two coarse fish species. In a comparison of predatory functional responses with a native crayfish (*Austropotamobius pallipes*), juvenile *E. sinensis* had a greater predatory intensity than the native *A. pallipes* on the keystone shredder *Gammarus pulex*, and also displayed a greater preference than *P. leniusculus* for this prey item. (3.) In outdoor mesocosms ($n = 16$) used to investigate community impacts, the abundance of amphipods, isopods, chironomids and gastropods declined in the presence of decapods, and a decapod >gastropod >periphyton trophic cascade was detected when both species were present. *Eriocheir sinensis* affected a wider range of animal taxa than *P. leniusculus*. (4.) Stable-isotope and gut-content analysis of wild-caught adult specimens of both invaders revealed a wide and overlapping range of diet items including macrophytes, algae, terrestrial detritus, macroinvertebrates and fish. Both decapods were similarly enriched in ^{15}N and occupied the same trophic level as Ephemeroptera, Odonata and Notonecta. *Eriocheir sinensis* $\delta^{13}\text{C}$ values were closely aligned with macrophytes indicating a reliance on energy from this basal resource, supported by evidence of

direct consumption from gut contents. *Pacifastacus leniusculus* $\delta^{13}\text{C}$ values were intermediate between those of terrestrial leaf litter and macrophytes, suggesting reliance on both allochthonous and autochthonous energy pathways. (5.) Our results suggest that *E. sinensis* is likely to exert a greater per capita impact on the macroinvertebrate communities in invaded systems than *P. leniusculus*, with potential indirect effects on productivity and energy flow through the community." 15667. Sanchez, S.; Wilson, D.E. (2016): Food items of *Macrotus waterhousii* (Chiroptera: Phyllostomidae) in central Mexico. *Therya* 7(1): 161-177. (in English, with Spanish summary) ["*Macrotus waterhousii* is a phyllostomid bat whose diet is poorly known, particularly in semiarid and temperate central Mexico. In this work additional information is reported from food remains discarded by this bat, including taxonomic composition, frequencies and size range of consumed insects; the assessment of a prediction on prey hardness of food insects, at the ordinal level; relative energy reward of insect prey in the sample; a comparison of the composition of the food sample from the arid study locality against one from a subtropical-temperate site; and brief comments on the known ecological importance of particular prey in the arid site. A sample of insect food remains discarded by *Macrotus waterhousii bulleri*, was recovered from under a roost in semiarid northern Querétaro, Mexico. The taxonomic identity, estimated relative abundance, size, hardness, and ecological relations of prey species in the sample were studied and results were compared with reference to feeding ecology. A comparison of the data with available information on food taken by *Macrotus waterhousii mexicanus* in temperate-subtropical central Mexico was made. Information on the importance of the most relevant identified insects was extracted from literature and analyzed. In Querétaro, Lepidoptera, Hymenoptera, and Coleoptera were frequent; moths dominated but, as a single species, the (winged) ant, *Atta mexicana* was most frequent. Nocturnal insects were frequent; diurnal ones may have been gleaned at night. A sample from Estado de México featured Orthoptera, Coleoptera, and Lepidoptera. Wingspan range of frequent prey in Querétaro was 25-80 mm, but moths over 70 mm were over one fifth of the sample. Prey hardness estimation was similar to that for *Macrotus californicus*. Some insects identified are of ecologic and agricultural relevance. Insects known to be seasonally abundant in the environment were also abundant in the sample, presumably captured according to that availability. However this bat, aside from eating insects of moderate size in proportion to its jaw size, is also capable of capturing

large moths and these may represent a significant energy intake. Most insects are nocturnal species. The taxonomic composition of the food samples from both areas suggests that *M. waterhousii* (sensu lato) may be mostly an opportunistic predator. Local insect fauna composition and dynamics may be hypothesized to influence food taken by *M. waterhousii*. Several insect species consumed by this bat in semiarid Querétaro have crucial roles in the ecology of arid land vegetation, as well as some economic importance for agriculture as pests." (Authors) Odonata *Anax* sp., *Erpetogomphus* sp., *Paltothemis* sp.) account less than 1% of diet items.]Address: Sánchez, S., Las Flores, San Lorenzo Tepaltitlán 50018, Estado de México, México. 15668. Scales, J.A.; Butler, M.A. (2016): The relationship between microhabitat use, allometry, and functional variation in the eyes of Hawaiian *Megalagrion* damselflies. *Functional Ecology* 30(3): 356-368. (in English) ["(1.) The evolution of visual systems is guided by the interaction of visual requirements imposed by habitat light heterogeneity, eye size, and physical limitations imposed by the resolution-sensitivity tradeoff. The physical constraints related to eye surface area result in a tradeoff between resolution, the ability of the eye to detect detail, and sensitivity, the ability to capture photons, so that both cannot be simultaneously maximized without increases to eye size. How this constraint interacts with ecology and whether it allows the fine tuning of the visual system to smaller scale habitat heterogeneity remains an understudied question in visual ecology. (2.) Here we use closely related species of damselflies in the Hawaiian genus *Megalagrion* which differ in ecology to test whether variation about the resolution-sensitivity tradeoff is the evolutionary result of scaling or differences in microhabitat use. We use regression analyses and phylogenetic comparative methods to examine the effects of size and microhabitat use on traits related to light sensitivity and visual resolution. (3.) We find that eye size is tightly associated with body size in these damselflies, but morphological traits related to light sensitivity and resolution are associated with microhabitat type. Furthermore, size and morphology relationships vary across microhabitats, and resolution tends to be more conserved than variation in light sensitivity. (4.) Additionally, smaller species in visually challenging microhabitats have more regionalized eyes than species with larger eyes in open, well-lit areas. Thus, regionalization of the eye allows a decoupling of size and morphology/performance so that even small insect species can exploit visually challenging habitats. (5.) These results suggest that variation in visual performance results from changes in eye geometry as well as size. These morphological changes are likely adaptive to differences in microhabitat indicating that variation in microhabitat use, even at small scales, can play an important role in the evolution of visual systems." SMP-NRVA: 45 pp. + 8pp app.. (in French, with English summary) ["Irish Damselfly (*Coenagrion lunulatum*) is a rare and endangered dragonfly found only in the French Massif Central and especially in the Volcans d'Auvergne Natural Regional Park (PNRVA). After two years of studies about inventory and larval habitat characterisation, 2015 is about moving capacities of this species. On the one hand, Mark-Release-Recapture method enables to understand the population dynamic of the species. On the other hand, recapture shows that *C. lunulatum* can moving punctually on distance longer than 4km. With the current knowledge about the species' ecology, the potential distribution of *C. lunulatum* on the PNRVA has been modelled. This map shows

some population cores well connected, and two isolated areas, in the North and in the South of PNRVA territory, due to small populations, relief, and woodland. Now, it must allow to define priority area where actions will be suggest to preserve this dragonfly." (Authors)] Address: not stated.

15672. Segura-Trujillo, C.A.; Lidicker, W.Z.; Álvarez-Castañeda, S.T. (2016): New perspectives on trophic guilds of arthropodivorous bats in North and Central America. *Journal of Mammalogy* 97(2): 644-654. (in English, with Spanish summary) ["Trophic guilds are useful concepts for advancing our knowledge of trophic structure of communities, dynamics of species interactions, redundancy in ecosystem services, resilience to disturbances, response to climate change, conservation strategies, etc. For insectivorous bats, current literature suggests 8 trophic-related guilds. These include 3 guilds based on the openness of foraging areas, 3 based on the style of feeding, and 2 recently proposed subguilds among gleaners. Some gleaners are "passive," using densely cluttered vegetation in which echolocation is ineffective, and others are "actively" gleaning, using echolocation to procure prey. None of these guilds is based on the actual diets of bats. We analyzed 33 reports of diet composition representing 51 species of arthropod-feeding bats inhabiting North and Central America. We wanted to determine if the classical guild structure was concordant with the actual diets of bats and to compare guild structure in the Nearctic with that in the Neotropics. Discriminant function and principle component analyses generated 5 groups of genera based on the proportion of various arthropod taxa (mainly orders) in their diets. These groups were very different from classical guilds and showed almost no overlap among bat genera between the 2 continental regions. A similar analysis based on prey flying ability and hardness of their exoskeletons suggested 4 guilds that were more consistent with classical guild concepts, had higher rates of unambiguous guild assignment, and also showed major continental differences. Our results suggest a new arrangement of 4 guilds for arthropod-feeding bats in North and Central America that are based primarily on 2 features of their prey. New molecular techniques should allow us to build on this arrangement by significantly improving the taxonomic level of prey identification." (Authors) The paper includes references to Odonata.] Address: Álvarez-Castañeda, S.T., Centro de Investigaciones Biológicas del Noroeste, Instituto Politécnico Nacional 195, Playa Palo de Santa Rita Sur, La Paz 23096, Baja California Sur, México. 15673. Shaffery, H.M.; Relyea, R.A. (2016): Dissecting the smell of fear from conspecific and heterospecific prey: investigating the processes that induce anti-predator defenses. *Oecologia* 180(1): 55-65. (in English) ["Prey use chemical cues from predation events to obtain information about predation risk to alter their phenotypes. Though we know how many prey respond to predators, we still have a poor understanding of the processes and chemical cues involved during a predation event. We examined how gray treefrog tadpoles (*Hyla versicolor*) altered their behaviour and morphology when raised with cues from different

stages of predator (*Anax junius*) attack, predators fed different amounts of prey, and predators consuming different combinations of treefrog tadpoles or snails (*Helisoma trivolvis*). We found that starved predators and predators fed snails induced no defensive responses whereas tadpoles exposed to a predator consuming gray treefrogs induced greater hiding, lower activity, and relatively deeper tails. We also found that the tadpoles did not respond to crushed, chewed, or digested conspecifics, but they did respond to consumed (i.e., chewed plus digested) conspecifics. When we increased the treefrog biomass consumed by predators, tadpoles frequently increased their defenses when only tadpoles were consumed and always increased their defenses when the total diet biomass was held constant via the inclusion of snails. When predators experienced temporal variation in diet composition, including cues from snails to cause additional digestive cues or chemical noise, there was no effect on tadpole phenotypes. Our results suggest that amphibian prey rely on cues from both chewing and digestion of conspecifics and that the presence of cues from digested heterospecifics play little or no role in adding chemical noise or increased digestive enzymes and by-products that could potentially interfere with induced defenses." 15675. Shyy, W.; Kang, C.-k.; Chirarattananon, P.; Ravi, S.; Liu, H. (2016): Aerodynamics, sensing and control of insect-scale flapping-wing flight. *Proc. R. Soc. A* 472: 20150712. <http://dx.doi.org/10.1098/rspa.2015.0712>: 37 pp. (in English) ["There are nearly a million known species of flying insects and 13000 species of flying warm-blooded vertebrates, including mammals, birds and bats. While in flight, their wings not only move forward relative to the air, they also flap up and down, plunge and sweep, so that both lift and thrust can be generated and balanced, accommodate uncertain surrounding environment, with superior flight stability and dynamics with highly varied speeds and missions. As the size of a flyer is reduced, the wing-to-body mass ratio tends to decrease as well. Furthermore, these flyers use integrated system consisting of wings to generate aerodynamic forces, muscles to move the wings, and sensing and

control systems to guide and manoeuvre. In this article, recent advances in insect-scale flapping-wing aerodynamics, flexible wing structures, unsteady flight environment, sensing, stability and control are reviewed with perspective offered. In particular, the special features of the low Reynolds number flyers associated with small sizes, thin and light structures, slow flight with comparable wind gust speeds, bioinspired fabrication of wing structures, neuron-based sensing and adaptive control are highlighted." 15676. Siepielski, A.M.; Fallon, E.; Boersma, K. (2016): Predator olfactory cues generate a foraging–predation trade-off through prey apprehension. *R. Soc. open sci.* 3: 150537. <http://dx.doi.org/10.1098/rsos.150537>: 7 pp. (in English) ["Most animals are faced with the challenge of securing food under the risk of predation. This frequently generates a trade off whereby animals respond to predator cues with reduced movement to avoid predation at the direct cost of reduced foraging success. However, predators may also cause prey to be apprehensive in their foraging activities, which would generate an indirect 'apprehension cost'. Apprehension arises when a forager redirects attention from foraging tasks to predator detection and incurs a cost from such multi-tasking, because the forager ends up making more mistakes in its foraging tasks as a result. Here, we test this apprehension cost hypothesis and show that damselflies (*Ischnura cervula*) miss a greater proportion of their prey during foraging bouts in response to both olfactory cues produced by conspecifics that have only viewed a fish predator and olfactory cues produced directly by fish (*Gambusia affinis*). This reduced feeding efficiency is in addition to the stereotypical antipredator response of reduced activity, which we also observed. These results show that costs associated with anti-predator responses not only arise through behavioural alterations that reduce the risk of predation, but also from the indirect costs of apprehension and multi-tasking that can reduce feeding efficiency under the threat of predation." 15678. Sivasankaran, P.N.; Ward, T.A. (2016): Spatial network analysis to construct simplified wing structural models for Biomimetic Micro Air Vehicles. *Aerospace Science and*

Technology 49: 259-268. (in English) ["A procedure for designing a simplified, dragonfly-like wing model that is suitable for use in a Biomimetic Micro Air Vehicle (BMAV) is presented. BMAV are a relatively new class of micro-scaled unmanned air systems that mimic the flapping wing propulsion system of flying biological organisms (like insects). Many insects (e.g. dragonflies) have complex wing vein and membrane patterns that are too small to fabricate using many types of machine cutting tools (e.g. micro laser cutting). Structural dynamic modification using the spatial network analysis approach is used to create a simplified model. Our objective was to minimize the wing vein patterns so that they were within our fabrication tolerances. Simulations were performed for both the detailed and simplified models. The natural frequency and corresponding mode shapes, modal assurance criterion (MAC) and static bend-twist coupling results were very similar. This analysis shows that a simplified model can be designed and fabricated to closely biomimic a real dragonfly wing." 15679. Sniegula, S.; Golab, M.J.; Drobniak, S.M.; Johansson, F. (2016): Seasonal time constraints reduce genetic variation in life-history traits along a latitudinal gradient. *Journal of Animal Ecology* 85(1): 187-198. (in English) ["(1.) Time constraints cause strong selection on life-history traits, because populations need to complete their life cycles within a shorter time. We therefore expect lower genetic variation in these traits in high- than in low-latitude populations, since the former are more time-constrained. (2.) The aim was to estimate life-history traits and their genetic variation in an obligately univoltine *Lestes sponsa* along a latitudinal gradient of 2730 km. (3.) Populations were grown in the laboratory at temperatures and photoperiods simulating those at their place of origin. In a complementary experiment, individuals from the same families were grown in constant temperature and photoperiod that mimicked average conditions across the latitude. (4.) Development time and size was faster and smaller, respectively, and growth rate was higher at northern latitudes. Additive genetic variance was very low for life-history traits, and estimates for egg development time and larval growth rate showed significant decreases towards northern latitudes. The expression of genetic effects in life-history traits differed considerably when individuals were grown in constant rather than simulated and naturally variable conditions. (5.) Our results support strong selection by time constraints. They also highlight the importance of growing organisms in their native environment for correct estimates of genetic variance at their place of origin. Our results also suggest that the evolutionary potential of life-history traits is very low at northern compared to southern latitudes, but that changes in climate could alter this pattern." 15681. Sugiura, S. (2016): Impacts of introduced species on the biota of an oceanic archipelago: the relative importance of competitive and trophic interactions. *Ecological Research* 31(2): 155-164. (in English) ["Introduced species negatively impact native species through competitive and trophic interactions, particularly on oceanic islands that have never been connected to any continental landmass. However, there are few studies on the relative importance of competitive interactions (resource competition with introduced species) and trophic interactions (predation or herbivory by introduced species) with respect to the negative impacts on native organisms on oceanic islands. A literature review on introduced and native species of the oceanic Ogasawara (Bonin) Islands in the western Pacific Ocean indicated that many native species (e.g., bees, beetles, damselflies, butterflies, land snails, birds, and plants) have been negatively impacted by introduced predators and herbivores (e.g., lizards, rats, flatworms, and goats). Several native plants and bees have been negatively affected by introduced competitors. However, the native species that have competed with introduced species have also suffered from either intense herbivory or predation by other introduced species. Thus, introduced predators and herbivores have had greater impacts on native species than introduced competitors in the Ogasawara Islands." (Holotype male deposited in FSCA: Ecuador, Esmeraldas Province, small stream 5.6 km NW of Lita, 00.893°N 78.510°W, 4.II.1997, KJT leg.) is described and illustrated based on specimens from Ecuador, Panama, Costa Rica, and Nicaragua, bringing the total number of species in the genus to five. The new species is closely related to *P. remissa* (Calvert), a Mexican/northern Central American species with broad, foliate male cerci, but is distinct in that the long flagella of the genital ligula lack a small sharp spine unique to *P. remissa*, labrum and clypeus are orangered, and the back of the head is mostly pale in both males and females. In life, the eyes of

the new species are bright red in males versus green and black in *P. remissa*." (Author)] Address: Tennessen, K., Florida State Collection of Arthropods, PO Box 585, Wautoma, WI 54982, USA. E-mail: ktennessen@centurytel.net

15683. Troast, D.; Suhling, F.; Jinguji, H.; Sahlén, G.; Ware, J. (2016): A global population genetic study of *Pantala flavescens*. *PLoS ONE* 11(3): e0148949. doi:10.1371/journal.pone.0148949: 13 pp. (in English) ["Among terrestrial arthropods, the dragonfly species *Pantala flavescens* is remarkable due to their nearly global distribution and extensive migratory ranges; the largest of any known insect. Capable of migrating across oceans, the potential for high rates of gene flow among geographically distant populations is significant. It has been hypothesized that *P. flavescens* may be a global panmictic population but no sufficient genetic evidence has been collected thus far. Through a population genetic analysis of *P. flavescens* samples from North America, South America, and Asia, the current study aimed to examine the extent at which gene flow is occurring on a global scale and discusses the implications of the genetic patterns we uncovered on population structure and genetic diversity of the species. This was accomplished using PCR-amplified cytochrome oxidase one (CO1) mitochondrial DNA data to reconstruct phylogenetic trees, a haplotype network, and perform molecular variance analyses. Our results suggested high rates of gene flow are occurring among all included geographic regions; providing the first significant evidence that *Pantala flavescens* should be considered a global panmictic population." 15684. Valente-Neto, F.; Roque, F.; Rodrigues, M.E.; Juen, L.; Swan, C.M. (2016): Toward a practical use of Neotropical odonates as bioindicators: Testing congruence across taxonomic resolution and life stages. *Ecological Indicators* 61(2): 952-959. (in English) ["Highlights: •We assessed environmental factors driving larvae and adults of odonates. •We evaluated the congruency between and within life-history stages. •Larvae vs. adult and adult genera vs. species were congruent. •Environmental variables were important to explain the congruence pattern. •For operational reasons, adult genera are recommended in biomonitoring programs. Abstract: Odonates are suggested as bioindicators of human impact. However, their complex life cycles add additional challenges in the practical use as bioindicators, because the level of taxonomic identification could be dependent on life-history stage and, during their ontogeny, dramatic changes occur in their niche (ontogenetic niche shifts). Considering that larvae and adults have different biological characteristics, which could interfere in their performance as bioindicators, we first sought to understand how similar or different environmental factors affect larval and adult life stages in the Odonata. Second, we assessed the level of congruence between (larvae and adult) and within (adult genera and species) life-history stages, considering the taxonomic and numerical resolution. We sampled larvae and adults in 44 streams distributed along a riverine

network in southwest Brazil. Larvae samples constituted 20 sampling units of 1 m length each, using the kick sampling method; adults were collected for 1 h at each site with a hand net along a 100-m transect parallel to the stream/river banks. The influence of environmental factors on larvae and adult was assessed by redundancy analysis coupled with forward selection. The congruence level between response matrices was determined by Procrustes analysis. Our results revealed that a set of environmental variables explained a portion of larvae and adults distribution and some environmental factors affect both between (larvae and adults) and within (adult genera and species) life-history stages. Larvae and adult were about 54% congruent, regardless of taxonomic level of adults. Abundance of adult genera and species were 94% congruent, but numerical resolution (abundance vs. incidence) decreased the congruency by 10%. Environmental variables could influence larvae and adults individually or via carry-over effects, i.e., larval environmental conditions that could affect adult fitness components or vice versa. In addition, some odonate behaviours, such as female selection of more appropriate habitats for laying their eggs, could also help us to explain our results, because it could determine larvae distribution. In a biomonitoring perspective, considering the cost-benefit of taxonomic level and sampling of larvae and adults, our results suggest that abundance of adult genera could be used in biomonitoring programs since they capture, respectively, 94% and 54% of the information carried by adult species and larvae." 15685. Van Dinh, K.; Janssens, L.; Therry, L.; Gyulavári, H.A.; Bervoets, L.; Stoks, R. (2016): Rapid evolution of increased vulnerability to an insecticide at the expansion front in a poleward moving damselfly. *Evolutionary Applications* 9(3): 450-461. (in English) ["Many species are too slow to track their poleward moving climate niche under global warming. Pesticide exposure may contribute to this by reducing population growth and impairing flight ability. Moreover, edge populations at the moving range front may be more vulnerable to pesticides because of the rapid evolution of traits to enhance their rate of spread that shunt energy away from detoxification and repair. We exposed replicated edge and core populations of the poleward moving damselfly *Coenagrion scitulum* to the pesticide esfenvalerate at low and high densities. Exposure to esfenvalerate had strong negative effects on survival, growth rate and development time in the larval stage and negatively affected flight-related adult traits (mass at emergence, flight muscle mass and fat content) across metamorphosis. Pesticide effects did not differ between edge and core populations, except that at the high concentration the pesticide-induced mortality was 17% stronger in edge populations. Pesticide exposure may therefore slow down the range expansion by lowering population growth rates, especially because edge populations suffered a higher mortality, and by

negatively affecting dispersal ability by impairing flight-related traits. These results emphasize the need for direct conservation efforts toward leading-edge populations for facilitating future range shifts under global warming." 15686. Vilela, D.S.; Ferreira, R.G.; Del-Claro, K. (2016): The Odonata community of a Brazilian vereda: seasonal patterns, species diversity and rarity in a palm swamp environment. *Biosci. J., Uberlândia* 32(2): 486-495. (in English, with Spanish summary) ["Studies concerning the occurrence of species and seasonality are of great importance for both the elucidation of species distribution and conservation of natural habitats. We performed a survey of Odonata species and studied their seasonality in an endemic endangered palm swamp (i.e. Veredas) environment of the Ecological Reserve of Clube de Caça e Pesca Itororó de Uberlândia, Southeastern Brazil. Between July 2010 and June 2011, we recorded 31 species of five different families and 21 genera. The community was strongly seasonal, since 24 species occurred in the wet season, while ten occurred in both dry and wet season, and only two species occurred only in the dry season. All Anisoptera species preferred lentic habitats, whereas seven of the 18 Zygoptera species preferred lentic habitats and 11 species preferred lotic sites. The five Calopterygidae and Protoneuridae species preferred lotic habitats. The study site exhibits a great diversity of dragonflies and damselflies, which are important elements of the trophic chain in the Cerrado aquatic and neighbouring land environments. This justifies the development of conservation actions in palm swamp areas, which are poorly known and threatened by the constant advance of urban, monoculture and pasture areas in Cerrado." 15687. Villalobos-Jimenez, G.; Dunn, A.M.; Hassall, C. (2016): Dragonflies and damselflies (Odonata) in urban ecosystems: A review. *Eur. J. Entomol.* 113: 217-232. (in English) ["The expansion of urban areas is one of the most significant anthropogenic impacts on the natural landscape. Due to their sensitivity to stressors in both aquatic and terrestrial habitats, dragonflies and damselflies (the Odonata) may provide insights into the effects of urbanisation on biodiversity. However, while knowledge about the impacts of urbanisation on odonates is growing, there has not been a comprehensive review of this body of literature until now. This is the first systematic literature review conducted to evaluate both the quantity and topics of research conducted on odonates in urban ecosystems. From this research, 79 peer-reviewed papers were identified, the vast majority (89.87%) of which related to studies of changing patterns of biodiversity in urban odonate communities. From the papers regarding biodiversity changes, 31 were performed in an urban-rural gradient and 21 of these reported lower diversity towards built up city cores. Twelve of the cases of

biodiversity loss were directly related to the concentrations of pollutants in the water. Other studies found higher concentrations of pollutants in odonates from built-up catchments and suggested that odonates such as *Aeshna juncea* and *Platycnemis pennipes* may be candidate indicators for particular contaminants. We conclude by identifying current research needs, which include the need for more studies regarding behavioural ecology and life-history traits in response to urbanisation, and a need to investigate the mechanisms behind diversity trends beyond pollution." 15688. Vinatier, F.; Lagacherie, P.; Voltz, M.; Petit, S.; Lavigne, C.; Brunet, Y.; Lescourret, F. (2016): An unified framework to integrate biotic, abiotic processes and human activities in spatially explicit models of agricultural landscapes. *Front. Environ. Sci.*, 02 February 2016 | <http://dx.doi.org/10.3389/fenvs.2016.00006> : 7 pp. (in English) ["Recent concern over possible ways to sustain ecosystem services has triggered important research worldwide on ecosystem processes at the landscape scale. Understanding this complexity of landscape functioning calls for coupled and spatially-explicit modelling approaches. However, disciplinary boundaries have limited the number of multi-process studies at the landscape scale, and current progress in coupling processes at this scale often reveals strong imbalance between biotic and abiotic processes, depending on the core discipline of the modellers. We propose a spatially-explicit, unified conceptual framework that allows researchers from different fields to develop a shared view of agricultural landscapes. In particular, we distinguish landscape elements that are mobile in space and represent biotic or abiotic objects (for example water, fauna or flora populations), and elements that are immobile and represent fixed landscape elements with a given geometry (for example ditch section or plot). The shared representation of these elements allows setting common objects and spatio-temporal process boundaries that may otherwise differ between disciplines. We present guidelines and an assessment of the applicability of this framework to a virtual landscape system with realistic properties. This framework allows the complex system to be represented with a limited set of concepts but leaves the possibility to include current modelling strategies specific to biotic or abiotic disciplines. Future operational challenges include model design, space and time discretization, and the availability of both landscape modelling platforms and data." 15689. Wellenreuther, M.; Sánchez-Guillén, R.A. (2016): Non-adaptive radiation in damselflies. *Evolutionary Applications* 9(1): 103-118. (in English) ["Adaptive radiations have long served as living libraries to study the build-up of species richness, however, they do not provide good models for radiations that exhibit negligible adaptive disparity. Here we

review work on damselflies to argue that non-adaptive mechanisms were predominant in the radiation of this group and have driven species divergence through sexual selection arising from male–female mating interactions. Three damselfly genera (*Calopteryx*, *Enallagma* and *Ischnura*) are highlighted and the extent of (i) adaptive ecological divergence in niche use and (ii) non-adaptive differentiation in characters associated with reproduction (e.g. sexual morphology and behaviours) evaluated. We demonstrate that species diversification in the genus *Calopteryx* is caused by non-adaptive divergence in colouration and behaviour affecting premating isolation, and structural differentiation in reproductive morphology affecting postmating isolation. Similarly, the vast majority of diversification events in the sister genera *Enallagma* and *Ischnura* are entirely driven by differentiation in genital structures used in species recognition. The finding that closely related species can show negligible ecological differences yet are completely reproductively isolated suggests that the evolution of reproductive isolation can be uncoupled from niche-based divergent natural selection, challenging traditional niche models of species coexistence." 15690. Wiwatanaratnabutra, I.; Zhang, C. (2016): *Wolbachia* infections in mosquitoes and their predators inhabiting rice field communities in Thailand and China. *Acta Tropica* 159: 153-160. (in English) ["*Wolbachia* are inherited, endocyttoplasmic bacteria that infect a wide range of arthropods. Here is the first systematic report on the study of *Wolbachia* infection in mosquitoes and their predators from both Thailand and China. In Thailand, 632 mosquito specimens (20 spp.) and 424 insect predators (23 spp.) were collected from the rice agroecosystem, mostly from the Central region, followed by the Northeast, the North and the South and were inhabiting rice fields, wetlands and ditches. In China, 928 mosquitoes (15 spp.) and 149 insect predators (16 spp.) were collected from rice fields along the Weishan Lake in Shandong province. Specimens were classified in the orders Diptera, Coleoptera, Odonata and Hemiptera. Using *wsp*, *ftsZ*, 16S rRNA and *groE* gene amplifications, *Wolbachia* were detected in 12 mosquito spp. and 6 predator spp. from Thailand and 11 mosquito spp. and 5 predator spp. from China. The relative *Wolbachia* densities of these species were determined using quantitative real-time PCR. The mosquito, *Aedes albopictus*, and the predator, *Agriocnemis femina*, had the highest bacterial densities. These results imply that *Wolbachia* of supergroup B are distributed throughout these insects, probably via horizontal transmission in rice agroecosystems." 15691. Worthen, W.B.; Hart, T.M. (2016): Resistance to *Arrenurus* spp. parasitism in odonates: Patterns across species and comparisons between a resistant and susceptible

host. *Journal of Insect Science* 16(1)(37): 6 pp. (in English) ["Some adult odonates resist parasitism by larval water mites (*Arrenurus* spp.) with melanotic encapsulation, in which the mite's styletome is clogged and the mite starves. In summer 2014, we counted the engorged and resisted mites on 2,729 adult odonates sampled by aerial net at 11 water bodies in Greenville Co. and Pickens Co., SC, and tested the hypothesis that the frequency and intensity of resistance correlates with parasite prevalence (the percentage of parasitized hosts). Resistance prevalence (the percentage of parasitized hosts that resisted at least one mite) varied significantly among host species, exceeding 60% for *Argia fumipennis* and *Celithemis fasciata* but less than 20% for other species. However, neither resistance prevalence nor mean resistance intensity (mean percentage of resisted mites on resisting hosts) correlated with parasite prevalence. We described potential effects of parasitism on host development of *A. fumipennis* and *Pachydiplax longipennis* by comparing the percent asymmetry of forewing lengths between parasitized and unparasitized individuals. There was no significant difference in asymmetry for either males or females of *A. fumipennis*, or males of *Pa. longipennis* (females were not sampled). We also evaluated differences in melanotic encapsulation between *A. fumipennis*, which readily encapsulates mites in nature, and *Pa. longipennis*. We inserted a 2.0-mm piece of sterile monofilament line into the thorax of captured individuals for 24h and compared mean gray value scores of inserted and emergent ends using Image-J software. There was no difference in melanotic encapsulation between species." (Authors)] Address: Hart, T.M., Biology Department, Furman University, Greenville, SC 29613, USA. E-mail: Thomasmhart0@gmail.com

15692. Xu, Q.; Lin, W.; Zhuang, F.; Shen, C.; Lin, X. (2016): Acute toxicity of three pesticides to *Orthetrum* larvae. *Chinese Agricultural Science Bulletin* 32(2): 73-76. (in Chinese, with English summary) ["To select efficient and safe pesticides and control dragonfly larvae in fishing ponds, acute toxicity tests of three pesticides (trichlorfon, bifenthrin and clothianidin) to last-stadium larvae of *Orthetrum* were performed respectively. The results showed that LC50 (96 h) values of trichlorfon, bifenthrin and clothianidin to last-stadium larvae of *Orthetrum* were 0.2506, 0.0012 and 0.0517 mg a.i./L, respectively. Comparing LC50 (96 h) values of the three pesticides to the last-stadium larvae of *Orthetrum*, freshwater fishes and the tadpole of *Rana grylio*, and the aquatic ecological characteristics of the three pesticides, clothianidin was recommended as the suitable pesticide for controlling dragonfly larvae in fishing ponds." 15695. Yeates, D.K.; Meusemann, K.; Trautwein, M.; Wiegmann, B.; Zwick, A. (2016): Power, resolution and bias: recent advances in insect phylogeny driven by the genomic revolution. *Current Opinion in Insect Science* 13: 16-23. (in English) ["Our understanding on the phylogenetic relationships of insects has been revolutionised in the last decade by the proliferation of next generation sequencing technologies (NGS). NGS has allowed insect systematists to assemble very large molecular datasets that include both model and non-model organisms. Such datasets often include a large proportion of the total number of protein coding sequences available for phylogenetic comparison. We review some early entomological phylogenomic studies that employ a range of different data sampling protocols and analyses strategies, illustrating a fundamental renaissance

in our understanding of insect evolution all driven by the genomic revolution. The analysis of phylogenomic datasets is challenging because of their size and complexity, and it is obvious that the increasing size alone does not ensure that phylogenetic signal overcomes systematic biases in the data. Biases can be due to various factors such as the method of data generation and assembly, or intrinsic biological feature of the data per se, such as similarities due to saturation or compositional heterogeneity. Such biases often cause violations in the underlying assumptions of phylogenetic models. We review some of the bioinformatics tools available and being developed to detect and minimise systematic biases in phylogenomic datasets. Phylogenomic-scale data coupled with sophisticated analyses will revolutionise our understanding of insect functional genomics. This will illuminate the relationship between the vast range of insect phenotypic diversity and underlying genetic diversity. In combination with rapidly developing methods to estimate divergence times, these analyses will also provide a compelling view of the rates and patterns of lineagenesis (birth of lineages) over the half billion years of insect evolution." 15696. Yu, P.; Cheng, X.; Ma, Y.; Yu, D.; Zhang, J. (2016): The complete mitochondrial genome of *Brachythemis contaminata* (Odonata: Libellulidae). *Mitochondrial DNA* 27(3): 2272-2273. (in English) ["In this study, we reported the complete mitochondrial genome of the dragonfly *Brachythemis contaminata* (Odonata: Libellulidae). The entire circular genome is 15,056 bp in length and represents the smallest in presently known odonatan mitogenomes. The DNA molecule contains 13 protein-coding genes, 2 rRNA genes, 22 tRNA genes and a non-coding control region of 323 bp. There were a total of 137 bp short intergenic spacers and 89 bp overlaps in the genome. The gene arrangement is similar to other dragonflies. The base composition of the genome is A (40.2%), T (32.8%), C (15.6%) and G (11.4%) with an AT content of 73.0%. Four start codons (ATA, ATT, ATC and ATG) and two stop codons (TAG and TAA/TA) were found in 13 protein-coding genes. The length of 22 tRNA genes ranged from 63 (trnP) to 72 bp (trnK)."] (Authors)] Address: Zhang, J., Institute of Ecology, Zhejiang Normal University, Jinhua 321004, Zhejiang Province, P. R. China. 15697. Yuto, C.M.M.; Lumogdang, L.; Tabugo, S.R.M. (2016): Fluctuating asymmetry as an indicator of ecological stress in *Rhinocypha colorata* (Odonata: Chlorocyphidae) in Iligan city, Mindanao, Philippines. *Entomology and Applied Science Letters* 3(1): 13-20. (in English) ["Odonata species are known to be successful biological indicators because they are particularly sensitive to human disturbances due to their habitat selection which makes them vulnerable to changes. A useful trait to monitor developmental instability (DI) and ecological stress is fluctuating asymmetry (FA),

which is a measure of the differences between the left and right side of bilateral symmetrical organisms. It refers to a slight number and nondirectional deviations from strict bilateral symmetry of biological objects that occur as a result of stochastic microscopic processes. In this study, fore-wing variation of *Rhinocypha colorata*, a Philippine endemic species was investigated. It assessed developmental stability via fluctuating asymmetry in the fore-wings of *R. colorata*, in three populations from three areas: Buruun, Dituclalan, Dalipuga, Iligan City, Mindanao, Philippines. Analysis was based on Procrustes method that makes comparison of FA indices of homologous points. Using landmark method for shape asymmetry, anatomical landmarks were used and analyzed using Symmetry and Asymmetry in Geometric Data (SAGE) program. Twenty landmarks on the fore-wings were tested on samples for all populations. Results obtained showed variation and significantly high FA for all populations with relatively higher FA for Dalipuga. Principal component analysis (PCA) showed that barangay Dalipuga exhibited more variations (74.93%) than that of Dituclalan (72.19%) and Buru-un (67.97%). Possible reasons behind high FA values were anthropogenic activities in the area. FA has been considered as a good indicator of DI and thus acts as a biomarker for environmental stress. Hence, results may reflect inability of the organism to cope with stressing factors and any perturbations during development. Here-with, understanding the relationship between the species and its environment would help determine the health of a given ecosystem. Nonetheless, Odonata, as bioindicator species, can play an important role for biomonitoring purposes." 15698. Zaliyati, A.M.; Shariff, S.M. (2016): Diversity of dragonfly communities at two habitats in Negeri Sembilan. *Regional conference on science, technology and social sciences (RCSTSS 2014)*: 557-564. (in English) ["Kuala Pilah and Batu kikir are located in Negeri Sembilan, Malaysia. The changes of flora and fauna community have always been related with the anthropogenic activities. This study was conducted in order to determine the species diversity of dragonfly within two different habitats in Negeri Sembilan. The sampling was carried out from August 2013 to October 2013 at two habitats comprising of UiTM Forest Reserve (Kuala Pilah) and Kampung Lonek Paddy Field (Batu Kikir). A total of 164 individuals of dragonflies were collected, which comprise of 14 species. For Kuala Pilah, a total of 11 species with 62 individuals were collected while for Batu kikir, a total of 9 species with 102 individuals were collected. Family Libellulidae was the dominant family that indicates 99 % of the total collected followed by one percent of total collected by Family Gomphidae. The highest total number of dragonfly individuals was shown by *Potamarcha congener* with 52 individuals that indicate 32 % of total collected while the least number of individuals was shown by the species of *Orthetrum chrysis*, *Tholymis tillarga*, and *Ictinogomphus decoratus* with one individual that indicate only one

percent, respectively. Thus, there was high species diversity ($H' = 1.9$), high species richness ($R = 2.423$), and high species evenness of dragonfly ($E = 0.792$) in UiTM Forest Reserve as compared to Kampung Lonek Paddy Field." 15700. Zheng, D.; Nel, A.; Wang, B.; Jarzembowski, E.; Chang, S.-C.; Zhang, H. (2016): The first Early Cretaceous damsel-dragonfly (Odonata: Stenophlebiidae: Stenophlebia) from western Liaoning, China. *Cretaceous Research* 61: 124-128. (in English) ["A well-preserved forewing of the damsel-dragonfly *Stenophlebia liaoningensis* sp. nov. is described from the Lower Cretaceous Yixian Formation in the Huangbanjigou Village, western Liaoning, China. This is the first discovery of the genus *Stenophlebia* in China, although it was widely distributed in Europe during the Late Jurassic. The discovery adds to the biodiversity of Stenophlebiidae in the Chinese Cretaceous, and provides insight on the evolution of this extinct family." 15701. Zheng, D.; Zhang, Q.; Chang, S.-C.; Wang, B. (2016): A new damselfly (Odonata: Zygoptera: Platystictidae) from mid-Cretaceous Burmese amber. *Cretaceous Research* 63: 142-147. (in English) ["The genus *Mesosticta* Huang, Azar, Cai et Nel, 2015 was established based on the wing bases of two damselflies from mid-Cretaceous Burmese amber. Here we describe a new well-preserved platystictid damselfly, *Mesosticta electronica* sp. nov., with complete forewings and hindwings. The diagnosis of *Mesosticta* is revised and augmented in this paper. *Mesosticta electronica* sp. nov. differs from *Mesosticta burmatica* Huang, Azar, Cai et Nel, 2015 in having the arculus slightly distal of Ax2, a free subdiscoidal cell, the hindwing AA ending on the middle area of the posterior side of the discoidal cell, and the base of RP2 being three or four cells distal of

the subnodus. The new discovery adds to the diversity of damselflies in mid-Cretaceous Burmese amber and puts the origin of Platystictidae to at least the mid-Cretaceous." (Authors)] Address: Zheng, D., State Key Laboratory of Palaeobiology and Stratigraphy, Nanjing Institute of Geology and Palaeontology, Chinese Academy of Sciences, 39 East Beijing Road, Nanjing 210008, China.
